SCIENCE

NEW SERIES. VOLUME XLI

JANUARY-JUNE, 1915

NEW YORK
THE SCIENCE PRESS
1915

- Cabrera, A., Fauna Ibérica, W. J. HOLLAND, 214
 Calkins, G. N., Biology, C. E. McCLEUNG, 580
 CALKINS, M. W., Psychology, E. M. OGDEN, 248
 CAMERON, F. K., Biochemistry and Soil Conditions, E. J. RUSSELL, 794
 CAMPBELL, D. H., Botany in America, 185
 CAMPBELL, W., Metallurgy, W. ROSENHAU, 762
 CAMPBELL, W. W., Pacific Assoc. of Sci. Societies, 687
 CANNON, A. J., Mrs. Henry Draper, 380
 CANNON, W. B., Physiology, L. LUCIANI, 289
 CARLSON, A. J., Amer. Physiol. Soc., 142
 Carnegie Institution, 191
 CARRUTH, F. E., and W. A. WITHERS, Gossypol, 324
 CASSINO, S. E., Naturalist's Directory, 502
 CASTLE, W. E., Mendelism and Mutation, 94
 CATTELL, J. MCKEN, Scientific Research, 729
 Cavern of Three Brothers, G. G. MACCUBRY, 782
 Cereal Investigations, Interstate Conference, 602
 CHAMBERS, B. J., Germ. Cell, 290
 Chemical Industry in Great Britain, 601, Amer. Soc., New Orleans Meeting, C. L. PARSONS, 697, Seattle Meeting, 817
 Chemist and Industry, B. C. HESS, 665
 Chicago Acad. of Sci., 586
 Child, E. G., Electric Arcs, R. G. HUDSON, 829
 CHINA, Medicine in, G. BLUMER, 940
 Chaparde, E., Letter, 634
 CLARK, A. H., Shark Intoxication, 795
 CLARK, G. A., Pristif Islands, 902
 CLARK, O. L., Counting Seeds, 132, Eye Screen for Microscope, 792
 CLARKE, J. M., New Glacial Park, 382
 Claypole, Edith Jane, 754
 Clinical Departments of Medical Schools, A. D. BEVAN, 388, G. LUSK, 531, Instruction, M. G. SEELIG, 594
 COBB, M. V., Origin of Human Twins, 501
 COCKERELL, T. D. A., Red Sunflower, 33, Wonder of Life, J. A. Thompson, 290, Ants, W. M. Wheeler, 906
 COCKS, R. S., New Orleans Acad. of Sci., 478, 664, 880
 COLE, A. D., The Nucleus Atom, 73, Amer. Physiol. Soc., 259, 841, San Francisco Meeting, 934
 COLE, F. N., Amer. Math. Soc., 144, 476, 698
 Commercial Geography and World Politics, 86
 COMPTON, K. T., and E. A. TROUSDALE, Magnetic Particle, 611
 CONKLIN, E. G., Zoology and Humanity, 338, August Weismann, 917
 Conserve the Collector, J. GRINNELL, 229
 Coral Reefs, W. M. DAVIS, 455
 Cornell Med. Soc. of N. Y. City, 892
 Cotton, Worm Moth, A. P. SAUNDERS, 65, J. H. GEROUUD, 464, Bleaching, B. S. LEVINE, 543
 COULTER, J. M., Charles E. Bessy, 599
 Counting Seeds, O. L. CLARK, 132
 COWLES, H. C., Economic Trend of Botany, 223
 Cragg, F. W., and W. S. PATTON, Medical Entomology, C. A. KOPON, 167
 CROSBY, M. S., Albumin, 678
 D. G. V. N., Forsyth Dental Infirmary, 30
 DALL, W. H., Magnetic Storms, K. BIRKELAND, 29
 DALL, W. H., Molluscan Fauna, G. D. HARRIS, 612
 Daly's Igneous Rocks, W. LINDGREN, 166
 DANFORTH, C. H., St. Louis Acad. of Sci., 108, 588
 DAVENPORT, C. H., Scientific Genealogy, 337
 DAVIS, B. M., Amer. Soc. Naturalists, 369
 DAVIS, W. M., Coral Reefs, 456
 DAY, A. L., Nat. Acad. of Sci., Washington Meeting, 566, Annual Meeting, 698
 Denudation, Continental, E. W. SHAW, 244
 DEWEY, J., Amer. Assoc. of University Professors, 147, A. O. LOVEJOY, and E. R. A. SELIGMAN, University of Utah, 685
 DILLON, J. S., Relief of Pacific Coast, 48
 Dinosaurs, Sphenoidal Sinus in, E. L. MOODIE, 388
 Discussion and Correspondence, 26, 63, 94, 131, 166, 207, 244, 288, 324, 358, 388, 424, 462, 501, 531, 575, 608, 644, 682, 725, 757, 790, 823, 868, 897, 939
 DOTEN, S. B., Agric. Exper. Stations, 138
 DOWNING, E. B., Secondary Schools, 232
 Draper, Mrs. Henry, A. J. CANNON, 380
 DRUMMOND, J., Albinism in English Sparrow, 579
 Dye, Lewis Landsey, F. STRONG, 380
 Dynamics, L. M. HOSKINS, 608, 684
 Earthquakes in Panama, D. F. McDONALD, 788
 Edison and Science, E. C. MACLAURIN, 618

SOME ASPECTS OF PROGRESS IN MODERN ZOOLOGY¹

It is our privilege to live in a time of almost unexampled progress in natural science—a time distinguished alike by discoveries of the first magnitude and by far-reaching changes in method and in point of view. The advances of recent years have revolutionized our conceptions of the structure of matter and have seriously raised the question of the transmutation of the chemical elements. They have continually extended the proofs of organic evolution but have at the same time opened wide the door to a reexamination of its conditions, its causes and its essential nature. Such has been the swiftness of these advances that some effort is still required to realize what remarkable new horizons of discovery they have brought into view. A few years ago the possibility of investigating by direct experiment the internal structure of atoms or the topographical grouping of hereditary units in the germ cells would have seemed a wild dream. To-day these questions stand among the substantial realities of scientific inquiry. And lest we should lose our heads amid advances so sweeping, the principles that guide scientific research have been subjected as never before to critical examination. We have become more circumspect in our attitude towards natural laws. We have attained to a clearer view of our working hypotheses—of their uses and their limitations. With the best of intentions

¹MS. Intended for publication and books etc. intended for review should be sent to Professor J. McKeen Cattell, Garrison 60 Hudson N. Y.

¹Address of the President of the American Association for the Advancement of Science, Philadelphia, December 28, 1914.

we do not always succeed in keeping them clear of metaphysics but at least we have learned to try. We perceive more and more clearly that science does not deal with ultimate problems or with final solutions. In order to live science must move. She attempts no more than to win successive points of vantage which may serve one after another as stepping stones to further progress. When these have played their part they are often left behind as the general advance proceeds.

In respect to the practical applications of science we have almost ceased to wonder at incredible prodigies of achievement yet in some directions they retain a hold on our imagination that daily familiarity can not shake. Not in our time at least will the magnificent conquests of sanitary science and experimental medicine sink to the level of the commonplace. Science here renders her most direct and personal service to human welfare and here in less direct ways she plays a part in the advance of our civilization that would have been inconceivable to our fathers. Popular writers delight to portray the naturalist as a kind of reanimated antediluvian wandering aimlessly in a modern world where he plays the part of a harmless visionary but what master of romance would have had the ingenuity to put into the head of his mythical naturalist a dream that the construction of the Panama Canal would turn upon our acquaintance with the natural history of the mosquito or that the health and happiness of nations—nay their advance in science letters and the arts—might depend measurably on the cultivation of our intimacy with the family lives of house flies, fleas and creatures of still more dubious antecedents!

1

Fourteen years ago to night it was my privilege to deliver an address before the

American Society of Naturalists entitled

Aims and Methods of Study in Natural History ² in which I indicated certain important changes that were then rapidly gathering headway in zoology. To night I once more ask attention to this subject as viewed in the fuller light of the remarkable period of progress through which biology has since been passing. I will not try to range over the whole vast field of zoology or to catalogue its specific advances. I will only permit myself a few rather desultory reflections suggested by a retrospect upon the progress of the past twenty five years. If my view is not fully rounded if it is colored by a long standing habit of looking at biological phenomena through the eyes of an embryologist I will make no apology for what I am not able to avoid. Let me remind you also at how many points the boundaries between this and other branches of biology have become obliterated. The traditional separation between zoology and botany for instance has lost all significance for such subjects as genetics or cytology. Again the artificial boundary often set up between zoology and animal physiology has wholly disappeared owing to the extension of experimental methods to morphology and of comparative methods to physiology. I trust therefore that our brethren in botany and physiology—perhaps I should include also those in psychology—will not take it amiss if I include them with us under the good old fashioned name of *naturalists*.

The sum and substance of biological inquiry may be embodied in two questions. What is the living organism and how has it come to be? We often find it convenient to lay the emphasis on one or the other of these questions but fundamentally they are inseparable. The existing animal bears

² SCIENCE N S XLII No 314 January 4 1901

the indelible impress of its past, the extinct animal can be comprehended only in the light of the present. For instance, the paleontologist is most directly concerned with problems of the past but at every step he is confronted by phenomena only to be comprehended through the study of organisms as they now are. Our main causal analysis of evolution must be carried out by experimental studies on existing forms. All this seems self-evident yet the singular fact is that only in more recent years have students of evolution taken its truth fully to heart. And here lies the key to the modern movement in zoology of which I propose to speak.

I do not wish to dwell on matters of ancient history, but permit me a word concerning the conditions under which this movement first began to take definite shape as the nineteenth century drew towards its close. In the first three decades after the "Origin of Species" studies upon existing animals were largely dominated by efforts to reconstruct their history in the past. Many of us will recall with what ardor naturalists of the time threw themselves into this profoundly interesting task. Many of us afterwards turned to work of widely different type but have our later interests, I wonder, been keener or more spontaneous than those awakened by the morphological historical problems, some of them already half forgotten, which we then so eagerly tried to follow? I am disposed to doubt it. The enthusiasm of youth! No doubt, but something more, too. Efforts to solve those problems have in the past often failed, they no longer occupy a place of dominating importance, but they will continue so long as biology endures because they are the offspring of an ineradicable historical instinct and their achievement stands secure in the great body of solid fact

which they have built into the framework of our science. Says Poincaré

The advance of science is not comparable to the changes of a city where old edifices are pitilessly torn down to give place to new, but to the continuous evolution of zoologic types which develop ceaselessly and end by becoming unrecognizable to the common sight, but where an expert eye finds always traces of the prior work of the centuries past. One must not think then that the old-fashioned theories have been sterile and vain.

And after all, science impresses us by something more than the cold light of her latest facts and formulas. The drama of progress, whether displayed in the evolution of living things or in man's age-long struggle to comprehend the world of which he is a product, stirs the imagination by a warmer appeal. Without it we should miss something that we fain would keep—something, one may suspect, that has played an important part at the higher levels of scientific achievement.

I seem to have been caught unawares in the act of moralizing. If so, let it charitably be set down as an attempt to soften the hard fact that thirty years after the

"Origin of Species" we found ourselves growing discontented with the existing methods and results of phylogenetic inquiry and with current explanations of evolution and adaptation. Almost as if by a preconcerted plan naturalists began to turn aside from historical problems in order to learn more of organisms as they now are. They began to ask themselves whether they had not been overemphasizing the problems of evolution at the cost of those presented by life processes everywhere before our eyes to day. They awoke to the insufficiency of their traditional methods of observation and comparison and they turned more and more to the method by which all the great conquests of physico-chemical science had been achieved, that which undertakes the analysis of phenom

ena by deliberate control of the conditions under which they take place—the *method of experiment*. Its steadily increasing importance is the most salient feature of the new zoology.

Experimental work in zoology is as old as zoology itself, nevertheless, the main movement in this direction belongs to the past two decades. I will make no attempt to trace its development, but let me try to suggest somewhat of its character and consequences by a few outlines of what took place in embryology.

The development of the egg has always cast a peculiar spell on the scientific imagination. As we follow it hour by hour in the living object we witness a spectacular exhibition that seems to bring us very close to the secrets of animal life. It awakens an irrepressible desire to look below the surface of the phenomena, to penetrate the mystery of development. The singular fact nevertheless is that during the phylogenetic period of embryological research this great problem though always before our eyes, seemed almost to be forgotten in our preoccupation with purely historical questions—such as the origin of vertebrates or of annelids, the homologies of germ layers, gill-slits or nephridia, and a hundred others of the same type. Now, these questions are and always will remain of great interest, but embryology, as at last we came to see, is but indirectly connected with historical problems of this type. The embryologist seeks first of all to attain to some understanding of development. It was therefore a notable event when, in the later eighties, a small group of embryologists headed by Wilhelm Roux turned away from the historical aspects of embryology and addressed themselves to experiments designed solely to throw light upon the mechanism of development. The full significance of this step first came home to

us in the early nineties with Driesch's memorable discovery that by a simple mechanical operation we can at will cause one egg to produce two, or even more than two, perfect embryos. I will not pause to inquire why this result should have seemed so revolutionary. It was as if the scales had fallen from our eyes. With almost a feeling of shock we took the measure of our ignorance and saw the whole problem of development reopened.

The immediate and most important result of this was to stimulate a great number of important objective investigations in embryology. But let me pause for a moment to point out that at nearly the same time a similar reawakening of interest in the experimental investigation of problems of the present became evident in many other directions—for example, in studies on growth and regeneration, on cytology and protozoology, on economic biology, on ecology, the behavior of animals and their reactions to stimuli, on heredity, variation and selection. The heaven was indeed at work in almost every field of zoology, and everywhere led to like results. It was a day of rapid obliteration of conventional boundary lines, of revolt from speculative systems towards the concrete and empirical methods of the laboratory, of general and far reaching extension of experimental methods in our science.

But I will return to embryology. It may be doubted whether any period in the long history of this science has been more productive of varied and important discoveries than that which followed upon its adoption of experimental methods. In one direction the embryologist went forward to investigations that brought him into intimate relations with the physicist, the chemist, the pathologist and even the surgeon. A flood of light was thrown on the phenomena of development by studies on differen-

tiation, regeneration, transplantation and grafting, on the development of isolated blastomeres and of egg fragments, on the symmetry and polarity of the egg, on the relations of development to mechanical, physical and chemical conditions in the environment, on isolated living cells and tissues cultivated like microorganisms, outside the body *in vitro*, on fertilization, artificial parthenogenesis and the chemical physiology of development. In respect to the extension of our real knowledge these advances constitute an epoch making gain to biological science. And yet these same researches afford a most interesting demonstration of how the remoter problems of science, like distant mountain peaks, seem to recede before us even while our actual knowledge is rapidly advancing. Thirty years after Roux's pioneer researches we find ourselves constrained to admit that in spite of all that we have learned of development the egg has not yet yielded up its inmost secrets. I have referred to the admirable discovery of Driesch concerning the artificial production of twins. That brilliant leader of embryological research had in earlier years sought for an understanding of development along the lines of the mechanistic or physico-chemical analysis, assuming the egg to be essentially a physico-chemical machine. He now admitted his failure and, becoming at last convinced that the quest had from the first been hopeless, threw all his energies into an attempt to resuscitate the half-extinct doctrines of vitalism and to found a new philosophy of the organism. Thus the embryologist, starting from a simple laboratory experiment, strayed further and further from his native land until he found himself at last quite outside the pale of science. He did not always return. Instead he sometimes made himself a new home—upon occasion even established him-

self in the honored occupancy of a university chair of philosophy!

The theme that is here suggested tempts me to a digression because of the clear light in which it displays the attitude of modern biology towards the study of living things. It is impossible not to admire the keenness of analysis, and often the artistic refinement of skill (which so captivates us for instance in the work of M. Bergson) with which the neo-vitalistic writers have set forth their views. For my part, I am ready to go further, admitting freely that the position of these writers *may* at bottom be well grounded. At any rate it is well for us now and then to be rudely shaken out of the ruts of our accustomed modes of thought by a challenge that forces upon us the question whether we really expect our scalpels and microscopes, our salt solutions, formulas and tables of statistics to tell the whole story of living things. It is of course, impossible for us to assert that they will. And yet the more we ponder the question the stronger grows our conviction that the "entelechies" and such like agencies conjured forth by modern vitalism are as sterile for science as the final causes of an earlier philosophy, so that Bacon might have said of the former as he did of the latter that they are like the Vestal virgins—dedicated to God, and barren. We must not deal too severely with the naturalist who now and then permits himself an hour of dalliance with them. An uneasy conscience will sooner or later drive him back into his own straight and narrow way with the insistent query. The specific vital agents *sui generis*, that are postulated by the vitalist—are they sober realities? Can the existence of an "élan vital," of "entelechies," of "psychoids" be experimentally verified? Even if beyond the reach of verification may they still be of prac-

tical use in our investigations on living things or find their justification on larger grounds of scientific expediency. However philosophy may answer, science can find but one reply. *The scientific method is the mechanistic method.* The moment we swerve from it by a single step we set foot in a foreign land where a different idiom from ours is spoken. We have it is true, no proof whatever of its final validity. We do not adopt the mechanistic view of organic nature as a dogma but only as a practical program of work, neither more nor less. We know full well that our present mechanistic conceptions of animals and plants have not yet made any approach to a complete solution of the problems of life, whether past or present. This should encourage us to fresh efforts, for just in the present inadequacy of these conceptions lies the assurance of our future progress. But the way of unverifiable (and irrefutable) imaginative constructions is not our way. We must hold fast to the method by which all the great advances in our knowledge of nature have been achieved. We shall make lasting progress only by plodding along the old, hard beaten trail blazed by our scientific fathers—the way of observation, comparison, experiment, analysis, synthesis, prediction, verification. If this seems a prosaic program, we may learn otherwise from great discoverers in every field of science who have demonstrated how free is the play that it gives to the constructive imagination and even to the faculty of artistic creation.

II

Thus far I have desired to emphasize especially the reawakening of our interest in problems of the present and the growing importance of experimental methods in our science. It is interesting to observe how these changes have affected our atti-

tude towards the historical problem as displayed in the modern study of genetics. Even here we are struck by the same shifting of the center of gravity that has been remarked in other fields of inquiry. In the Darwinian era studies on variation and heredity seemed significant mainly as a means of approach to the problems of evolution. The post-Darwinians awoke once more to the profound interest that lies in the genetic composition and capacities of living things as they now are. They turned aside from general theories of evolution and their deductive application to special problems of descent in order to take up objective experiments on variation and heredity for their own sake. This was not due to any doubts concerning the reality of evolution or to any lack of interest in its problems. It was a policy of masterly inactivity deliberately adopted for further discussion concerning the causes of evolution had clearly become futile until a more adequate and critical view of existing genetic phenomena had been gained. Investigators in genetics here followed precisely the same impulse that had actuated the embryologists and they too reaped a rich harvest of new discoveries. Foremost among them stands the rediscovery of Mendel's long forgotten law of heredity—a biological achievement of the first rank which in the year 1900 suddenly illuminated the obscurity in which students of heredity had been groping. Another towering landmark of progress is De Vries's great work on the mutation theory published a year later which marked almost as great a transformation in our views of variation and displayed the whole evolution problem in a new light. In the era that followed the study of heredity quickly became not only an experimental but almost an exact science, fairly comparable to chemistry in its systematic employment

of qualitative and quantitative analysis, synthesis, prediction and verification. More and more clearly it became evident that the phenomena of heredity are manifestations of definite mechanism in the living body. Microscopical studies on the germ cells made known an important part of this mechanism and provided us with a simple mechanical explanation of Mendel's law. And suddenly in the midst of all this by a kaleidoscopic turn the fundamental problem of organic evolution crystallizes before our eyes into a new form that seems to turn all our previous conceptions topsy-turvy.

I will comment briefly on this latest view of evolution partly because of its inherent interest but also because it again exemplifies as in the case of embryology that temptation to wander off into metaphysics (*sic venia verborum*) which seems so often to be engendered by new and telling discoveries in science. The fundamental question which it raises shows an interesting analogy to that encountered in the study of embryology and may conveniently be approached from this side.

To judge by its external aspects individual development like evolution would seem to proceed from the simple to the complex but is this true when we consider its inner or essential nature? The egg appears to the eye far simpler than the adult yet genetic experiment seems continually to accumulate evidence that for each independent hereditary trait of the adult the egg contains a corresponding *something* (we know not what) that grows divides and is transmitted by cell division without loss of its specific character and independently of other somethings of like order. Thus arises what I will call the puzzle of the microcosm. Is the appearance of simplicity in the egg illusory? Is the hen's egg fundamentally as complex

as the hen and is development merely the transformation of one kind of complexity into another? Such is the ultimate question of ontogeny which in one form or another has been debated by embryologists for more than two centuries. We still cannot answer it. If we attempt to do so each replies according to the dictates of his individual temperament—that is to say he resorts to some kind of symbolism and he still remains free to choose that particular form which he finds most convenient provided it does not stand in the way of practical efforts to advance our real knowledge through observation and experiment. Those who must have everything reduced to hard and fast formulas will no doubt find this rather disconcerting but worse is to follow. Genetic research now confronts us with essentially the same question as applied to the evolutionary germ. The puzzle of the microcosm has become that of the macrocosm. Were the primitive forms of life really simpler than their apparently more complex descendants? Has organic evolution been from the simple to the complex or only from one kind of complexity to another? May it even have been from the complex to the simple by successive losses of inhibiting factors which as they disappear set free qualities previously held in check? The last of these is the startling question that the president of the British Association propounded in his recent brilliant address at Melbourne asking us seriously to open our minds to the inquiry. Whether evolution can at all reasonably be represented as an unpacking of an original complex which contained within itself the whole range of complexity which living things exhibit? This conception manifestly is nearly akin to the theory of pangenesis and individual development as elaborated especially by De Vries and by Weismann. It inevitably re-

calls also, if less directly, Bonnet's vision of "palingenesis," which dates from the eighteenth century

We should be grateful to those who help us to open our minds, and Professor Bateson, as is his wont, performs this difficult operation in so large and masterly a fashion as to command our lively admiration. It must be said of his picturesque and vigorous discussion that we are kept guessing how far we are expected to take it seriously or at least literally. We have always a lurking suspicion that possibly his main purpose may after all be to remind us, by an object lesson, how far we still are from comprehending the nature and causes of evolution, and this suspicion is strengthened by the explicit statement in a subsequent address, delivered at Sydney, that our knowledge of the nature of life is "altogether too slender to warrant speculation on these fundamental questions." Let us, however, assume that we are seriously asked to go further and to enter the *cul de sac* that Professor Bateson so invitingly places in our way. Once within it, evidently, we are stalemated in respect to the origin and early history of life, but as to that, one form of total ignorance is perhaps as good as another, and we can still work out how the game has been played, even though we can never find out how the pieces were set up. But has the day so soon arrived when we must resign our selves to such an ending? Are we prepared to stake so much upon the correctness of a single hypothesis of allelomorphism and dominance? This hypothesis—that of "presence and absence"—has undoubtedly been a potent instrument of investigation, but there are some competent students of genetics who seem to find it equally simple to formulate and analyze the phenomena by the use of a quite different hypothesis, and one that involves no such paradoxical consequences in respect to the nature of

evolution. Are we not then invited to strain at a gnat and to swallow a camel?

But I pass over the technical basis of the conception in order to look more broadly at its theoretic superstructure. Is not this, once again, a kind of symbolism by which the endeavor is made to deal with a problem that is for the present out of our reach? Neither you nor I, I dare say, will hesitate to maintain that the primordial *Amœba* (if we may so dub the earliest of our ancestors) embodied in some sense or other all the potentialities, for better or for worse, that are realized before us at this moment in the American Association for the Advancement of Science. But if we ask ourselves exactly what we mean by this we discover our total inability to answer in more intelligible terms. We can not, it is true, even if we would, conquer the temptation now and then to spread the wings of our imagination in the thin atmosphere of these upper regions; and this is no doubt an excellent tonic for the cerebrum provided we cherish no illusions as to what we are about. No embryologist, for example, can help puzzling over what I have called the problem of the microcosm, but he should be perfectly well aware that in striving to picture to his imagination the organization of the egg, of the embryological germ, that is actually in his hands for observation and experiment, he is perilously near to the habitat of the mystic and the transcendentalist. The student of evolution is far over the frontier of that forbidden land, in any present attack upon the corresponding problem of the macrocosm, for the primordial *Amœba*, the evolutionary germ, is inconceivably far out of our reach, hidden behind the veil of a past whose beginnings lie wholly beyond our ken. And why, after all, should we as yet attempt the exploration of a region which still remains so barren and remote?

Surely not for the lack of accessible fields of genetic research that are fertile and varied enough to reward our best efforts, as no one has more forcibly urged or more brilliantly demonstrated by his own example than Professor Bateson himself.

Perhaps it would be the part of discretion to go no further. But the remarkable questions that Professor Bateson has raised concerning the nature of evolution leave almost untouched the equally momentous problem as to what has guided its actual course. In approaching my close I shall be bold enough to venture a step in this direction, even one that will bring us upon the hazardous ground of organic adaptations and the theory of natural selection. I need not say that this subject is beset by intricate and baffling difficulties which have made it a veritable bone of contention among naturalists in recent years. In our attempts to meet them we have gone to some curious extremes. On the one hand, some naturalists have in effect abandoned the problem cutting the Gordian knot with the conclusion that the power of adaptation is something given with organization itself and as such offers a riddle that is for the present insoluble. In another direction we find attempts to take the problem in flank—to restate it, to ignore it—sometimes, it would almost seem to argue it out of existence. It has been urged in a recent valuable work—by an author, I hasten to say, who fully accepts both the mechanistic philosophy and the principle of selection—that fitness is a reciprocal relation, involving the environment no less than the organism. This is both a true and a suggestive thought, but does it not leave the naturalist floundering amid the same old quicksands? The historical problem with which he has to deal must be grappled at closer quarters. He is everywhere confronted with specific devices in the organ-

ism that must have arisen long after the conditions of environment to which they are adjusted. Animals that live in water are provided with gills. Were this all we could probably muddle along with the notion that gills are no more than lucky accidents. But we encounter a sticking point in the fact that gills are so often accompanied by a variety of ingenious devices, such as reservoirs, tubes, valves, pumps, strainers, scrubbing brushes and the like that are obviously tributary to the main function of breathing. Given water, asks the naturalist, how has all this come into existence and been perfected? The question is an inevitable product of our common sense. The metaphysician, I think is not he who asks but he who would suppress it.

For all that it would seem that some persons find the very word adaptation of too questionable a reputation for mention in polite scientific society. Allow me to illustrate by a leaf taken from my own notebook. I once ventured to publish a small experimental work on the movements of the freshwater Hydra with respect to light. What was my surprise to receive a reproof from a friendly critic, because I had not been content with an objective description of the movements but had also been so indiscreet as to emphasize their evident utility to the animal. I was no doubt too young then—I fear I am too old now—to comprehend in what respect I had sinned against the light. That was long ago. I will cite a more recent example from a public discussion on adaptation that took place before the American Society of Naturalists a year or two since. "The dominance of the concept of adaptation," said one naturalist, "which now distinguishes our science from the non biological ones, is related to the comparatively youthful stage of development so far attained by biology, and not to any observed character in the

living objects with which we deal." Here we almost seem to catch an echo from the utterances of a certain sect of self-styled "scientists" who love to please themselves with the quaint fancy that physical disease is but one of the "errors of mortal mind."

Now, it is undoubtedly true that many adaptations to cite Professor Bateson once more, are "not in practice a very close fit." Even the eye as Helmholtz long ago taught us, has some defects as an optical instrument, nevertheless it enables us to see well enough to discern some food for reflection concerning adaptations among living things. And it is my impression that efforts to explain adaptations are likely to continue for the reason that naturalists as a body perhaps influenced by Huxley's definition of science have an obstinate habit of clinging to their common sense.

At the present day there is no longer the smallest doubt of the great outstanding fact that many complex structural adaptations—it would probably be correct to say all such—have not come into existence at a single stroke but have moved forward step by step to the attainment of their full degree of perfection. What has dominated the direction and final outcome of such advancing lines? We can not yet answer this question with any degree of assurance, but procrastinate as we may it must in the end squarely be faced. We have seen one theory after another forced back within narrower lines or crumbling away before the adverse fire of criticism. I will not pause to recount the heavy losses that must be placed to the account of sexual selection, of neo-Lamarckism, of orthogenesis. Some naturalists, no doubt, would assign a prominent place in this list of casualties to natural selection but probably there are none who would hold that it has been destroyed utterly. The crux lies in the degree

of its efficacy. Stated as an irreducible minimum the survival of the fit is an evident fact. Individuals that are unfitted to live, or to reproduce, leave few or no descendants—so much at least, must be admitted by all. But does this colorless and trite conclusion end the matter or adequately place before us the significance of the facts? Just here lies the whole issue. Does destruction of the unfit accomplish no other result than to maintain the *status quo*, or has it conditioned the direction of progress? Accepting the second of these alternatives Darwin went so far as to assign to it a leading role among the conditions to which the living world owes its existing configuration. Since his time the aspect of the problem has widely changed. We must rule out the question of the origin of neutral or useless traits. We must not confuse the evolution of adaptations with the origin of species. We must bear in mind the fact that Darwin often failed to distinguish between non-heritable fluctuations and hereditary mutations of small degree. We are now aware that many apparently new variations may be no more than recombination products of preexisting elements. We should, no doubt, make a larger allowance for the role of single "lucky accidents" in evolution than did many of the earlier evolutionists. And yet, as far as the essence of the principle is concerned I am bound to make confession of my doubts whether any existing discussion of this problem affords more food for reflection, even to day than that contained in the sixth and seventh chapters of the "Origin of Species" and elsewhere in the works of Darwin.

Undeniably there is a large measure of truth in the contention that natural selection still belongs rather to the philosophy than to the science of biology. In spite of many important experimental and

critical studies on the subject Darwin's conception still remains to day in the main what it was in his own time a theory a logical construction based it is true on a multitude of facts yet still awaiting adequate experimental test Simple though the principle is its actual effect in nature is determined by conditions that are too intricate and operate through periods too great to be duplicated in the experimental laboratory Hence it is that even after more than fifty years of Darwinism the time has not yet come for a true estimate of Darwin's proposed solution of the great problem

But there is still another word to be said Too often in the past the facile formulas of natural selection have been made use of to carry us lightly over the surface of unsuspected depths that would richly have repaid serious exploration In a healthy reaction from this purblind course we have made it the mode to minimize Darwin's theory and no doubt a great service has been rendered to our study of this problem by the critical and sceptical spirit of modern experimental science But there is a homely German saying that impresses upon us the need of caution as we empty out the bath lest we pour out the child too This suggests that we should take heed how we underestimate the one really simple and intelligible explanation of organic adaptations inadequate though it now may seem that has thus far been placed in our hands And in some minds—if I include my own among them let it be set down to that indiscretion at which I have hinted—the impression grows that our preoccupation with the problem as it appears at short focus may in some measure have dimmed our vision of larger outlines that must be viewed at longer range that we may have emphasized minor difficulties at the cost of a larger truth To such minds it will seem that the principle of natural selection

while it may not provide a master key to all the riddles of evolution still looms up as one of the great contributions of modern science to our understanding of nature

I have taken but a passing glance at a vast and many sided subject I have tried to suggest that the tide of speculation in our science has far receded that experimental methods have taken their rightful place of importance that we have attained to a truer perspective of past and present in our study of the problems of animal life The destructive phase through which we have passed has thoroughly cleared the ground for the new constructive era on which we now have entered All the signs of the times indicate that this era will long endure And this is of good augury for a future of productive effort guided by the methods of physico-chemical science impatient of merely *a priori* constructions of academic discussions of hypotheses that can not be brought to the test of experimental verification The work ahead will make exacting technical demands upon us The pioneer days of zoology are past The naturalist of the future must be thoroughly trained in the methods and results of chemistry and physics He must prepare himself for a life of intensive research of high specialization but in the future even more than in the past he will wander in vain amid the dry sands of special detail if the larger problems and general aims of his science be not held steadfastly in view For these are the outstanding beacon lights of progress and while science viewed at close range seems always to grow more complex a wider vision shows that her signal discoveries are often singularly simple This perhaps may help us to keep alive the spirit of the pioneers who led the advances of a simpler age and it is full of hope for the future

EDMUND B. WILSON

COLUMBIA UNIVERSITY

NATIONAL ACADEMIES AND THE PROGRESS OF RESEARCH II

USES OF AN ACADEMY BUILDING

In addition to experimental and illustrated lectures, the Academy might advantageously maintain exhibits freely open to the public, showing the current researches of its members, the most recent European advances in science, and new applications of scientific methods in the industries. It goes without saying that ample space and the best of facilities would be required for this purpose. If carefully worked out, this plan should provide an additional means of keeping the public informed of the progress of research and its bearing on the industries of the country. While emphasis should always be laid in such exhibits on pure science, which it is the Academy's prime object to advance, some of the most striking illustrations of the applications of science should also be introduced.

It is obvious that the Academy can not undertake such activities unless it can obtain a large building of its own. The advantages of having such a building for other purposes have already been touched upon. The attractiveness of the annual meetings would be greatly enhanced if they were held in such surroundings as an Academy building could supply. There is a very real difference between the atmosphere of bare halls, casually occupied, and attractively furnished rooms, permanently belonging to the Academy, and charged with the stimulating traditions accumulated during the process of time. The walls should be hung with portraits of past presidents and other eminent men of science, which could easily be obtained if there were a place for them. Moreover, the example of the Royal Society in preserving Newton's telescope and of the Royal Institution in exhibiting the original instruments of Davy, Faraday and other

great investigators, should be followed as soon as possible by the National Academy. Doubtless it is still feasible to secure instruments used by Joseph Henry, the two Agassizs, and others who have played a similar part in the history of the Academy. A permanent committee, charged with the collection of portraits, manuscripts, and instruments, and exercising care and discrimination in its selections, would gradually bring together many objects which would become more and more valuable with the passage of time.¹⁸

HISTORICAL EXHIBITS

[Few writers on civilization in America appreciate how largely the United States has contributed to the development of certain fields of research. The mathematical memoirs of Gibbs were of fundamental importance, while in such fields as celestial mechanics, practical astronomy, astrophysics, experimental physics, geology and paleontology, and in many of the newer phases of biology and experimental medicine, National Academy members have led the way in a long series of advances. An exhibit of original instruments, manuscripts, and photographs, arranged so as to show the successive contributions of American investigators in various departments of research, would prove an inspiration to many a young and enthusiastic aspirant to the pleasures of original discovery. I shall never forget my own delight in first seeing some of Henry Draper's original negatives of stellar spectra. Many of these are now in the possession of the Academy, ready for use in an exhibit of continuous progress in astronomical spectroscopy covering the

¹⁸ [A committee of this kind, which was appointed in November, 1913, has already received from Mrs. Henry Draper valuable instruments and original negatives illustrating the pioneer researches in astrophysics of the late Henry Draper.]

whole history of the Academy. Rutherford's first successful diffraction gratings and large scale photographs of the solar spectrum, Draper's spectra of stars and planets, the first to show the lines, Young's pioneer observations of the spectra of sun spots and the chromosphere, Langley's bolometric investigations in the invisible region of the infra red, and his measures of the solar constant of radiation, Pickering's extensive discoveries and classification of stellar spectra photographed with the objective prism, Rowland's invention of the concave grating and his fundamental studies of solar and laboratory spectra, Michelson's ingenious and varied contributions to the instruments of spectroscopy, comprising the interferometer, echelon and large grating, and his researches with them, Keeler's studies of celestial spectra in inaugurating the era of accurate radial velocity measurements, Campbell's perfection of the stellar spectrograph and the far reaching results of his years of observation. Each of these American investigators marked a distinct epoch in astrophysical research and their labors form a continuous chain covering the entire life of their subject. It is still possible to obtain many of their original instruments and earliest photographs, and to exhibit them in an attractive manner. Who would not like to see an actual spectrum formed by Rowland's earliest grating? A touch of a button operating an arc light mounted before the spectroscope slit, is all that would be necessary. And if this can be done in one field of research, there is no reason why similar stimulus can not be given in others, though of course in varying degree. If many subjects can show any such series of advances as we have seen in astronomical spectroscopy, the pessimism shown by some writers regarding American research must surely give way to optimism. And no

method of bringing the true state of affairs to easy comprehension, both to men of science and to the public, could equal that of the proposed exhibit. It goes without saying that the ingenious and attractive devices of modern museums should be employed instead of the dry and forbidding exhibition methods of former times.]

The committee on historical apparatus might also have charge of instruments belonging to the various trust funds and no longer in use by the persons to whom the original grants for their purchase were made. In the course of time such a collection would naturally grow to considerable proportions, and the Academy would be enabled to assist its members by the loan of these instruments as the Royal Society has done so effectively. The objection which is sometimes made to the purchase of standard instruments by the recipients of grants would thus be removed as such instruments might prove of great service in a collection for general use.

TENTATIVE DESIGN OF AN ACADEMY BUILDING

[The design of an Academy building here reproduced¹⁹ is intended merely as a

¹⁹ [From preliminary sketches by the firm of Shepley, Rutan and Coolidge. Some of the designs of rooms here employed should be modified. The name 'conversaz one room' for the large public hall comes from the annual conversaz ones of the Royal Society where many instruments and experimental exhibits are shown. The photographic room (not needed on this floor) should be used for council meetings setting free the room allotted in the plan to the council for a members ante room adjoining the meeting room. The meeting lecture and exhibition halls are shown in Fig. 2 as extending up through the second floor but the laboratories and other parts of the building would be divided into several stories of ordinary height. The laboratories may of course be devoted to any desired field of research and the designations are merely intended to suggest that one of these be in the physical and the other in the biological sciences.]

FIG 1

FIG 2

basis for discussion. The large public hall into which the main entrance leads is for the proposed exhibit of current research, illustrating the latest advances in pure and applied science, both American and foreign. The public would undoubtedly appreciate an opportunity to see under microscopes the most recently discovered bacilli, and to examine specimens illustrating the experimental variation of plants or animals, photographs showing new astronomical discoveries, experimental demonstrations of physical phenomena like the recently found Stark effect (the influence of an electric field on radiation), the structure of crystals, X-ray spectra and their bearing on the constitution of the atom, etc. As the home of such an exhibit, and the place of publication of the *Proceedings*, announcing the current advances of American research, the Academy would soon be recognized in its true character as the natural center and promoter of the scientific work of the United States.

In the adjoining room to the right the exhibit of historical research would connect the present with the past, and give a clear picture of American progress in the field of science. The possibilities of this exhibit have already been mentioned, but it may be remarked here that one of its prime purposes should be to stimulate further investigation and to aid in the Academy's work of correlating science by indicating converging lines of research. Both of these objects are of course perfectly compatible with the initial idea of commemorating the labors of Academy members.

The lecture hall at the rear of the building completes the group of rooms open to the public. This should embody some of the features which make the lecture hall of the Royal Institution so attractive. The provision of ample facilities for experi-

mental demonstrations (including a well-equipped preparation room) which no large lecture hall in Washington contains at present, would add greatly to the means of interesting both men of science and the public.

To the left of the central hall is the Academy meeting room, which might advantageously combine various features found in European academies. One of the most attractive meeting rooms abroad is that of the Paris Academy of Sciences. The provision of a comfortable ante room,²⁰ equipped like a club and providing abundant opportunity for conversation among members, would be a valuable addition. Instead of admitting visitors to the meeting room they could be better accommodated in a second floor gallery, above the ante room, similar to the visitors' gallery of the Amsterdam Academy. Finally, a modified seating arrangement (probably retaining the tables for officers and members) would permit the inclusion of a screen and experiment table at one end of the room.

The main floor would also contain a council room²¹ and various offices, cloak rooms, serving rooms, apparatus rooms, etc., needed for use in connection with meetings, lectures, exhibits, public receptions and other functions. The offices of the secretaries, editorial rooms, library and reading rooms, private research rooms and other rooms not for public purposes would be on the floors above. The example of the Berlin Academy²² which provides numerous offices (45 in all) in its new building for the compilation of data required for a general catalogue of stars, bodies of

²¹ In the space here marked "Photograph Room."

²² See "The Work of European Academies," SCIENCE, November 14, 1913, p. 692.

Greek and Latin inscriptions, a great Egyptian dictionary, and other similar undertakings, might well be imitated here. For instance, it would have been of great advantage to the Academy if it had been able to furnish Professor Newcomb with offices for the computers employed in his extensive astronomical researches, during the active period which followed his retirement from the Nautical Almanac office. Small study rooms for members staying in Washington, engaged in writing or research involving the use of the Academy library, would also be useful.

The two wings shown to the right and left of the main building are intended for research laboratories. While the great majority of members seem to favor the inclusion of such laboratories in the Academy's scheme of development there are a few who do not, and it is desirable to point out why they appear desirable. The Academy stands, first and foremost, for research, which it seeks to advance in every effective way. It may thus follow the example of various academies abroad, such as St. Petersburg, which carries on important researches in physics and other subjects, Stockholm, which has long provided in its own laboratories for the spectroscopic investigations of Hasselberg, and Berlin, which has produced the extensive investigations already enumerated. Nothing could do more to advance the Academy's influence on the progress of science than the production of important results from its own laboratories. But there is another and even stronger argument in favor of their establishment.

It has been well said by one who has studied the problems of the Academy, that the success of its future work must depend upon the discovery of men who are willing and able to devote the necessary time and energy to it. Two Academy members, in

commenting on suggestions for a building, remark that not laboratories, but *men* are needed. Those who are familiar with the history of the Academy are aware of the great amount of unselfish effort which it owes to its officers and members. But the fact remains that a man's first allegiance is to the university or other institution which counts him on its staff. As long as he retains such connections he can devote only his spare time to the work of the Academy, which, nevertheless, demands his best efforts.

The provision of research laboratories, with funds for their maintenance, would enable the Academy to command the entire time and effort of some of the ablest men in the country. The growing work, which already throws heavier burdens than the members realize on the willing shoulders of the Home Secretary, may later demand (as in the Royal Society) the services of two men, one representing the mathematical and physical, the other the biological sciences. The only way to secure the undivided service of such men is to offer them adequate salaries, a suitable staff of assistants, and ample laboratory facilities. Thus, while carrying on their researches in the name of the Academy, they would be able to direct the extensive work which the exhibits of current and historical research, the publication of the *Proceedings* and other contemplated activities must involve. Their position would be much like that of Faraday at the Royal Institution, with added duties defined by the broader range of the Academy's field.

An important object of the proposed research laboratories, therefore, is to attract and hold the men whose unrestricted time and energy the Academy urgently needs. Volunteer service will continue and multiply, but it can never hope to accomplish all that the future will require.

No details of laboratory design need be discussed here. The use of the unit system of rooms, exemplified in the Harvard Medical School, would eliminate many difficulties, and facilitate alterations to meet changing needs. A common plant of refrigerating machinery, compression pumps, constant temperature rooms and other requirements of both laboratories, could be placed on the ground floor of the main building, which would also contain rooms for storing reserve Academy publications and for other miscellaneous purposes.

Enough has been said to indicate some of the possible uses of an Academy building, and the corresponding necessities of the design. The present plan, which is merely tentative, may serve to bring out criticisms and suggestions from members who will undoubtedly think of many advantageous modifications. A classic treatment is indicated but this is mainly because of the prevailing conditions in Washington, and the probability that a government site could not be obtained for a building of collegiate Gothic design, for example.

It would be advantageous for the Academy to appoint a strong committee, representing all branches of science, to design a suitable building. Much time and thought are necessary to secure a satisfactory plan, which will provide for present needs, and be readily adaptable to future developments. As for funds, some time may be required to find the sum needed, but the opportunity is such an exceptional one that a willing donor is sure to appear in the future. The only way to obtain gifts for building or endowment is to have a scheme so promising, and plans so attractive as to convince a prospective investor that his funds will be effectively used. Notable cases might be cited where large gifts followed the presentation of effective building designs, which appealed

not only to the eye, but equally to the judgment of the donor.]

TRUST FUNDS

The trust funds of the Academy, as shown in a previous article, have a total of over eighty thousand dollars, the income of which is exclusively devoted to research. In addition, there are other funds totaling over thirty six thousand dollars, primarily intended for the endowment of medals and prizes, which enjoy a considerable surplus income also available for original investigation. By these means the Academy has been able to assist many of the most important researches of American science. A closer connection between the various committees, and the adoption of a concerted plan of action, would perhaps increase still further the usefulness of the funds. As a committee charged with the study of the use of trust funds has admirably expressed it

The Academy should take the initiative in the organization and conduct of research. It should not wait for applications or for suggestions to come in wholly from the outside. Such suggestions should be urged but the Academy should not relegate itself to the function of a mere disbursing organization, it should seek rather to determine what projects are worthy of investigation and how the funds may be most judiciously administered.

Such a policy would seem to imply a careful examination on the part of each committee of the existing conditions and needs of research in its own field, and an endeavor, through cooperation with the other committees to secure a well balanced and thoroughly effective use of all Academy funds available for investigation. As already suggested, the gradual accumulation of instruments, returned on the completion of the work for which they were purchased, should ultimately result in a marked gain in the efficiency of the funds.

and in the Academy's ability to assist in investigators

[As a body which is rapidly becoming truly representative of the investigators of America, the National Academy is well qualified to act in an advisory capacity to other institutions having funds available for use in research. It frequently happens that trustees of funds thus applicable require such expert advice as the Academy can give. A parallel case is that of the Royal Society, which selects annually the recipients of the Government Grant Fund of £4,000

MEDALS AND PRIZES

In bestowing the Academy's gold medals for investigations in physics, astronomy, astrophysics, oceanography and the study of meteoric bodies, an attempt should be made, not only to recognize and reward successful investigators but to do this in accordance with the best interests of future research. A few of the numerous medals awarded by academies, such as the Copley Medal of the Royal Society, may be advantageously reserved as a fitting recognition of many years of eminent service to science. But, as Diels²³ has justly remarked, the majority of medals and prizes will prove of greater value if given to comparatively young men who still need support and encouragement. By acquaintance with the circumstances under which such men are working, an award may be made at a moment so favorable as to increase its value many fold. Thus recognition by the Academy may supply the precise argument needed to convince university authorities or others in control of research funds of the importance of providing the means necessary to continue and extend the work of the medallist. The same may be said

of grants from trust funds. Cases are known in which a comparatively small grant has favorably influenced a board of trustees in deciding to devote large sums to research.

This leads to a consideration of the question of membership in the National Academy. In his valuable discussion of the organization of science to which reference has already been made, Professor Diels lays great emphasis upon the importance of aiding and encouraging the younger men of science through the award of grants for investigation. That this feeling is general throughout the German academies is shown by the fact that approximately one half of their resources are used for this purpose. Diels also finds cause for congratulation in the fact that the papers of these non-academicians published in the proceedings, often prove to be the most brilliant of Germany's contributions to science and at the same time greatly aid in enlivening the work of the Academies.²⁴

Nothing could point more clearly to the best field of usefulness of our own National Academy. As the future of research depends directly upon the younger men, the Academy may properly devote a large share of its efforts to their support and advancement. But moral encouragement is no less important than financial aid. The latter may well be given from the trust funds of the Academy, but the former should not be neglected. The Academy does grant medals, but these are available in only a few fields of research.²⁵ Fortunately it also possesses a still more powerful resource in its opportunity to be

²³ Diels *ibid* p. 665

²⁵ An attempt should be made to secure medals (or preferably money prizes available for the purchase of books or instruments) for mathematics, engineering, chemistry, geology, and the various branches of biology.

²⁴ "Die Kultur der Gegenwart," Teil I, Abteilung I, zweite Auflage, p. 666

stow all the advantages and privileges of actual membership

MEMBERSHIP

The great European academies differ among themselves in many particulars most of all as regards membership. At one extreme we find the St. Petersburg Academy with a president, a director and fifteen members who are paid good salaries and provided with dwelling houses and laboratory facilities. At the other extreme stands the Royal Society with 477 members who receive no salaries or other tangible benefits. The other leading academies such as Berlin, Paris, Rome and Vienna lie between these limits.⁴⁶

The large membership of the Royal Society probably reflects in some degree the strongly democratic tendencies of England. But the working body of scientific investigators is sufficiently large to prevent the distinction of election to this venerable society from being impaired. In fact on account of the great pains taken by the Council to inquire into the qualifications of the fifteen Fellows elected annually the significance of the coveted title of F.R.S. is perhaps even greater to day than at any earlier period in the history of the Society.

It can hardly be doubted that investigators of real ability are quite as numerous in the United States as in England. The available statistics indeed indicate that a much greater number of men are engaged here in research. The conditions are thus very different from those existing in 1863 when the National Academy was founded with 50 members as its limiting number. Since 1906 when the maximum number of members elected annually was increased from five to ten there has been a very perceptible change in the spirit of the Acad-

emy. By taking in a larger proportion of the younger men actively engaged in research the Academy has increased its contact with living issues and made itself more truly representative of American science. For the present the election of ten new members annually may suffice but I believe that the time will soon come when the limit should be raised from ten to fifteen.

It can not be gainsaid that a large number of able American investigators who in England would certainly be elected to membership in the Royal Society are still outside of our National Academy. The reason for this lies partly in the limit imposed on membership and partly in the method of nomination which seems to me susceptible of improvement. One difficulty which will certainly increase in the future has come about through the development of new fields of research. A man classed as a mathematician or an astronomer both of which subjects are well represented in the Academy is sure to receive consideration when nominations are being made. But if his subject be a comparatively new one not represented among the nominating sections included in the existing classification of the Academy his claims to recognition will be much less likely to command due attention. The constitution provides that the Council may nominate new members but this privilege is exercised only in rare cases and in any event there are certain disadvantages in this procedure. I trust that some means can be found of improving the system of nominations so as to overcome this difficulty which now deprives the Academy of valuable members.⁴⁷

As for the qualifications of membership it can hardly be doubted that the original plan of basing selections solely on the original contributions to science of the candidates should always be maintained. While

⁴⁶ See *The Work of European Academies*, SCIENCE 38: 686 et seq. 1913.

⁴⁷ [A committee is now at work on this subject.]

it is true that eminent administrators and others who exercise large influence in the intellectual world might prove to be of great service as members of the Academy, a wide departure from this fundamental principle would soon detract from the standing of the Academy as the national representative of original research. Thus while eminent services to the public should by no means be excluded from the field of the Academy's interests and may well be recognized by the award of special medals founded for this purpose actual membership should be confined to original investigators.

SCOPE OF THE ACADEMY

Here we may inquire as to the true scope of the Academy's work. In what degree should it confine its choice of members to the physical and natural sciences, and in what measure may it recognize successful research in such fields as philosophy, archeology, political economy, and history? The answer to this question will depend in part upon one's opinion of the chief object of the Academy. There are those who feel that the most important function of the National Academy is to confer distinction by election to membership. If this were its prime object the participation of the members in the work of the Academy would be a minor matter and any one of sufficient reputation as an investigator might be chosen. But if we agree as I think the large majority will, that the Academy should be looked upon as a working body, and that its privilege of conferring distinction by election to membership is only one of many important functions, it seems to me that a means of defining our choice of investigators in the humanities may easily be found.

A single philologist, or a single political economist, may find but little of interest to

himself in the proceedings of a body made up almost exclusively of representatives of the physical and natural sciences. If so, he may not attend the meetings, and his membership would then serve merely as a mark of distinction. Deferring for a moment the discussion of the broad question whether the Academy should ever be reorganized in two or more large classes, after the manner of the Berlin Academy, it seems to me that we should augment the value of election by furnishing real reason to every member for participation in the work of the Academy. For example, in its committee on anthropology and psychology the National Academy now has three members engaged in the study of archeological problems. Although their work relates primarily to American ethnology, it differs in no essential respect from that of the classical archeologist or the student of Egyptology or Assyriology. Would it not be advisable therefore, when the Academy chooses its next member from outside the domain of the physical and natural sciences to elect an archeologist from one of these fields? If this were done he might be expected to take a more active interest in the work of the Academy which would benefit by his contributions to its proceedings.²⁵

The advantages which might result from a wider extension of the scope of the National Academy raise the question whether an organization resembling that of the Berlin Academy will ever become desirable. This problem was long and seriously discussed by the Royal Society, and the negative decision of its deliberations led to the establishment of the British Academy. In spite of this decision, some of its leading

²⁵ William Dwight Whitney and William James resigned from the Academy, probably because they were the sole representatives of their subjects.

Fellows still believe that the Royal Society should have made room for a larger body of philosophers, historians and philologists than it now contains. Both the Royal Society and the National Academy have wisely refused to limit their membership to the physical and natural sciences. Such historians as Bryce and Morley and such Egyptologists as Petrie are now counted among the Fellows of the Royal Society, and Weld states that 116 archeological papers were published in the *Philosophical Transactions* before 1848.⁹⁹ But the large proportion of Fellows concerned with the physical and natural sciences, and the failure of the Society to recognize the philosophical historical group in its organization, has prevented the Royal Society from taking part in the Section of Letters of the International Association of Academies, where the British Academy now represents England.

The National Academy, as a member of the Section of Science of the International Association, is in a position to secure adequate representation in foreign affairs of American interests in the natural sciences. The United States are also entitled to representation in the Section of Letters, but the present organization of the National Academy and the absence of a national body similar to the British Academy,¹⁰⁰ still leaves a vacancy there.

In my opinion it would not be advisable, under present conditions, to reorganize the National Academy on the model of the Berlin Academy. But I am heartily in sympathy with the idea of widening its scope and its field of interests, in some such way as that indicated above. This plan would permit the Academy to honor able

investigators outside of the physical and natural sciences, and at the same time gradually to build up small groups of these members who would aid the Academy in the development of its work. Ultimately the Academy might extend this phase of its activities sufficiently to secure representation in the Section of Letters of the International Association of Academies.

LOCAL ACADEMIES

A subject to which I have devoted special attention in the study of the problems of the National Academy, is its relationship to the various local academies which are widely distributed over the United States. These societies are of the greatest importance in the further development of American research, and the cultivation of an intelligent interest in the problems of science. Some of them have grown to such large proportions and established such excellent organizations that they need no assistance or encouragement from the National Academy. But after these exceptional societies have been excluded, there remain a great number of others, which the National Academy ought to be in a position to assist in various ways.

In an early period of its history, the Paris Academy of Sciences established close official relations with certain provincial academies in various parts of France. In fact, the Society of Montpellier is described in its royal letters patent as "an extension and a part" of the Paris Academy of Sciences.¹⁰¹ But a general plan of federation between the provincial academies and the Institute of France, such as that described by Boullier in the work just cited, has never been carried into effect, and the old official relations have been discontinued. After careful consideration of Boullier's

⁹⁹ "History of the Royal Society," Vol 2, p 565

¹⁰⁰ The National Institute of Arts and Letters occupies a different field.

¹⁰¹ Boullier, "L'Institut et les Académies de Province," p 70

plan I doubt whether it could be advantageously applied in the United States under existing conditions

This conclusion however does not mean that the National Academy can not be of service to local organizations I believe on the contrary that it might find many ways and means of aiding them The prime object is to secure a high standard of accomplishment among the minor academies remote from the chief centers of research and to give the encouragement which the production of good work under unfavorable conditions so richly deserves It should be possible to discover methods of realizing these ends and thus to contribute to the strength and standing of the local academies and the progress of American research

[It will be noticed that comparatively little attention has been given in this paper to the relationship of the Academy to the national government This is due to no underestimate of the importance of the connection but rather to the strong desire that this chief implication of the Academy's charter should ultimately be realized in the fullest sense Valuable suggestions for cooperation with various departments of the government have been made by Academy members and every effort should be exerted to carry them into effect But recent experience indicates that the most promising way to accomplish this lies in first developing the standing and prestige of the Academy When it becomes more widely and favorably known for its contributions to scientific progress and is universally recognized as the national and authoritative representative of American science the Academy's influence with Congress and with the various officers of the government will be far more potent than at present I therefore believe that no effort should be made to press a demand for

greater government recognition until the publication of the *Proceedings* and other new activities have had time to produce their anticipated effect]

In summarizing the suggestions offered in this paper we see that many of the new activities proposed for the National Academy can not be undertaken without a suitable building If this can be obtained and adequately endowed the Academy will be able greatly to extend its influence and usefulness both at home and abroad through original researches increased service to members public lectures and exhibits and greater cooperation in international projects Under present conditions the International Association of Academies could hardly be invited to meet in Washington But if established in a home of its own the Academy might ultimately succeed the Royal Society and the Academies of Paris Rome St Petersburg and Berlin as the leading Academy of the Association for a period of three years In this position it could contribute in a more effective way to the furtherance of international science and to the study of the great problems of cooperative research which offer large possibilities of extension and development

The one way to secure a building and endowment is to prove by continual increase of efficiency that the Academy can use them to advantage The establishment of *Proceedings* the institution of lecture courses the encouragement of broader methods of science teaching and closer identification with the general interests of science as represented in all movements for the promotion of research and the diffusion of scientific knowledge are opportunities open to immediate realization and deserving of

⁵² I hope to discuss the international relations of the Academy in a future article

the most careful consideration by the Academy

SCIENTIFIC NOTES AND NEWS

THE sixty sixth meeting of the American Association for the Advancement of Science, in conjunction with a large number of national scientific societies is meeting in Philadelphia, as we go to press, under the presidency of Dr Charles W Eliot, of Harvard University. The address of the retiring president, Dr Edmund B Wilson, of Columbia University, is printed in the current issue of *SCIENCE*. We hope to print next week an account of the meeting to be followed by the more important addresses and papers and accounts of the proceedings of the section of the association and of the national societies.

DR C S SHERRINGTON has been elected Fullerian professor of physiology at the Royal Institution for a term of three years the appointment to date from January 15 1915.

At the annual meeting and election of the Academy of Natural Sciences held on December 15, the following were elected: *President* Dr Samuel G Dixon, *vice presidents* Edwin G Conklin, PhD, and John Cudwalader, *recording secretary and librarian* Dr Edward J Nolan, *corresponding secretary* J Percy Moore, PhD, *treasurer* George Vaux, Jr., *curators* Dr Samuel G Dixon, Henry A Pilsbry, Dr Witmer Stone and Dr Henry Tucker, *councillors* Charles B Penrose Charles Morris Spencer Trotter and William E Hughes.

DR LOUIS SCHAPIRO, of Milwaukee, has accepted an appointment on the International Health Commission of the Rockefeller Foundation. After traveling through the southern states with other members of the commission, Dr Schapiro will go to Costa Rica. After initiating work in the eradication of intestinal parasites, he will leave it in charge of local physicians and then probably will take charge of the work in northern Egypt.

R D HILTZEL director of extension for the Oregon Agricultural College, has been appointed chairman of the extension section of the American Association of Agricultural Colleges and Experiment Stations for the coming year.

SIR ERNEST and Lady Rutherford and Miss Fileen Rutherford spent a week in Montreal on their way home from New Zealand. Sir Ernest addressed the Physical and Chemical Societies of McGill University at a joint meeting on December 23 on "The Spectrum of X rays and γ rays."

For the purpose of studying the art, history and ethnology of China at close range, an expedition soon will be sent abroad by the University of Pennsylvania Museum under the direction of C W Bishop, who has been curator since last June. His appointment was made with the idea of his leading this expedition. Mr Bishop will first study Chinese art collections in the ancient cities of Japan at Nikko, Nara and Kioto where the temples and palaces contain some of the finest specimens in the world. He will then proceed to China and his first explorations will cover a year of preliminary work. Special attention will be given to the art and ethnology of the Shans, Loles and Miotzes, which are remnants of the primitive tribes before the Chinese invasion.

DR SIMON R KLIN formerly professor of histology and embryology in Fordham University School of Medicine New York City, has been appointed pathologist of the Norwich State Hospital for the Insane.

THE professors of chemistry of The Ohio State University gave a complimentary dinner on December 14 to Mr John J Miller, who is retiring from the editorship of *Chemical Abstracts*.

THE natural history department of the British Museum has the following men serving at the front in the war: Captain E E Austen (Diptera) with the 28th County of London Regt (Artists Rifles), private K G Blair (Coleoptera), with the 4th Battalion Seaforth Highlanders, Lieutenant N D Riley (Lepi-

doptera) with the Army Service Corps private C Court Treatt (Birds) with the 28th City of London private A K Totton (sponges etc) with the 28th City of London Lieutenant Campbell Smith (Mineralogy) with the 28th City of London There are also many assistants serving for example nine from the department of zoology All were unwounded as recently as December 4 Many of the museum staff who are unable to go into active service have been formed into a detachment of the Red Cross Society

PROFESSOR WILLIAM M CAMPBELL of the department of physics of New York University has resigned to take the position of president of the American Savings Bank

F D SANDERS IV dean of the college of agriculture and director of the West Virginia agricultural experiment station of West Virginia University has resigned to take effect on September 1 It is stated that he expects to pursue graduate studies

WALTER HARVEY WELF mining geologist has removed his offices and that of the *Copper Handbook* of which he is editor and owner to 29 Broadway New York City

DR VICTOR C VAUGHAN of the University of Michigan president of the American Medical Association was the guest of the St Louis Medical Society at its meeting on December 12 and addressed the members on Professional Ideals Dr Abraham Jacoby of New York also delivered a short address

A DISCUSSION on preventive inoculation was opened by Professor G Sims Woodhead at a meeting of the Royal Sanitary Institute at 90 Buckingham Palace Road on December 15 The chair was taken by Sir Shirley Murphy

DR JOSEPH T ROTHROCK general secretary of the Pennsylvania Forestry Association at the annual meeting held on December 14 advocated the use of the forest reserve lands of this state as outing grounds for the training of young men in physical endurance

PROFESSOR U S GRANT of Northwestern University Evanston Ill lectured on December 10 before the State Microscopical Society

of Illinois in Chicago upon 'The preparation of rock and mineral sections and their structure'

SIR FREDERIC EVE in his Bradshaw lecture before the Royal College of Surgeons of England on December 15 dealt with acute hemorrhagic pancreatitis and the etiology of chronic pancreatitis

A MEETING of the John Morgan Memorial Committee of the Philadelphia Alumni Society Medical Department University of Pennsylvania has been held to consider plans looking toward the erection of a suitable memorial which shall do honor to the man who is called the founder of medicine in the United States

SAMUEL BENEDICT CHRISTY professor of mining and metallurgy in the University of California and dean of the college of mining died in Berkeley California on November 30, 1914 at the age of sixty one years A graduate of the University of California of 1874, he had been continuously a member of its faculty since that time He was a pioneer in the development of the cyanide process for the treatment of refractory ores The engineers whom he has trained hold positions of great importance all over the world At one time there were more of his graduates in important positions in South Africa than from all the other American universities put together In 1902 he was given the degree of ScD by Columbia The Hearst Memorial Mining Building built by Mrs Phoebe A Hearst some years ago as a mining laboratory for the university at a cost of \$640 000 embodies Professor Christy's ideas as to equipment for mining and metallurgical instruction

THE death is reported in his sixty second year of Dr John Nisbet forestry adviser to the Scottish Board of Agriculture

ACCORDING to the *Journal* of the American Medical Association the International Health Commission of the Rockefeller Foundation has established laboratory stations for the diagnosis and treatment of hookworm at Panama, La Chorrera and Bocas del Toro The work

was organized by Dr L W Hackett of the commission and according to the *Canal Record* October 28 out of the first thousand men women and children reporting at the La Chorrera laboratory more than 700 were found to be harboring hookworm. An effort is being made to induce every inhabitant of this village of 4000 to submit to examination for hookworm and circulars in simple language have been distributed and house to house visits and investigations have been made. Treatment is free but not compulsory although the work is carried on at the request and with the co-operation of the Panama government and pressure may be brought to bear to make the campaign a thorough one. The establishment of laboratories in Panama is in pursuance of the plan of the International Health Commission for a world wide campaign of health work in countries requesting the cooperation of the commission. Panama was one of the first countries to invite assistance. Great Britain has already solicited cooperation in behalf of her tropical possessions and a French and Dutch colonial service and an oriental service are also under consideration.

"In 20 years the reindeer industry has made the Eskimos of Alaska civilized and thrifty men," says the United States Bureau of Education in a bulletin just issued. The reindeer industry began in Alaska in 1892 when the Bureau of Education imported from Siberia 171 reindeer. The object of the importation according to the bulletin was to furnish a source of supply for food and clothing to the Eskimos in the vicinity of Bering Strait. This importation was continued until 1902 and a total of 1280 reindeer were brought from Siberia. There are now 47206 reindeer distributed among 62 herds and 30532 of these are owned by the natives. This industry has given to the Alaskan Eskimos not only food and clothing but a means of transportation superior to dog teams. Instead of being nomadic hunters eking out a precarious existence on the vast untimbered lands of the Arctic coast region "the Eskimos" according to the Bureau's bulletin "Now have assured support and opportunity to acquire

wealth by the sale of meat and skins to the white men." The reindeer industry is carefully guarded. No native is permitted to sell or otherwise dispose of a female reindeer to any person other than a native of Alaska." This is done the bulletin states lest white men deprive the natives of their reindeer and destroy this great native industry which the Bureau of Education has in the last 20 years built up and fostered. The reindeer service is an integral part of the educational system of the Bureau of Education for northern and western Alaska. The district superintendents of schools are also superintendents of the reindeer service. Promising and ambitious young natives are selected by superintendents as apprentices in the reindeer service receiving 6, 8 or 10 reindeer at the close of the first second and third years respectively and 10 more at the close of the fourth year. Upon the satisfactory termination of his apprenticeship the native becomes a herder and assumes entire charge of a herd.

UNIVERSITY AND EDUCATIONAL NEWS

MR G S YUILL a graduate of Aberdeen University has made a gift of £4000 to the university the interest upon this amount to be applied in furthering the study of chemistry.

MRS A HOSMER of Oakland has presented to the University of California several thousand sand molluscan shells selected from the museum of the late Henry Hemphill who assembled the most notable museum of Pacific coast molluscan shells ever collected.

DR GEORGE HERBERT EVANS of San Francisco has been appointed assistant clinical professor of medicine in the University of California Medical School.

MR T V BARKER fellow of Brasenose College Oxford has been appointed university lecturer in chemical crystallography and Mr A G Gibson Christ Church, university lecturer in morbid anatomy.

THE chair of medicine and clinical medicine in the University of Edinburgh has become vacant through the retirement of Professor John Wyllie.

DISCUSSION AND CORRESPONDENCE

GONIONEMUS MURBACHII MAYER

THE following note may be of interest to those who, since the discovery of *G. murbachii* in the "Eel Pond" at Woods Hole in 1894, have observed its persistence during succeeding summers at the original locality and have noted its rare occurrence elsewhere along the Sound.

According to Mayer' this medusa has been found occasionally in Woods Hole Harbor and has been reported from Noank, Connecticut and from Hadley Harbor, Muskeget (Muskeget) Island.

In the summer of 1911 while collecting zoological material at Groton, Conn., I found *G. murbachii* in abundance at Pine Island, off Avery Point near the mouth of Poquonock River. This locality is five miles west of Noank. The little animals were common during the month of July and could usually be collected almost any time of the day by disturbing the rockweed along the sheltered side of the wharf at the west end of the island.

During a trip made in August of 1914 I failed to find the medusa at this place and was unable to locate it in the vicinity.

AMHERST, MASS.

NOTE ON AMOBA CLAVELLINAE NOV. SP.

THIS species may be recommended to the attention of any worker desirous of investigating a parasitic *Amoeba* which is visible *in vivo* within its host.

Its habitat is the stomach of *Clavellina lepadiformis*, where I noticed it from April to June 1910 at Naples. The cilia of the stomach wall keep it in constant rotation. When the host individuals are small they are almost transparent, and the ceaselessly whirling mass of parasites at once attracts attention.

In shape the organism is subspherical, pseudopodia were never observed. The average diameter varies from 12μ to 17μ . An ectoplasm may be present and sharply defined, or it may be totally absent. The nucleus is nearly spherical, with a diameter of 4μ to 5μ , in it is

"Medusae of the World," 1910, p. 344

a nucleus of 2μ to $2\frac{1}{2}\mu$ diameter, containing a vacuole or two. The nuclear membrane is thick and definite. In the clear space between membrane and nucleolus is a band or ring of tangible material usually in the form of fine granules. No division figures or further stages in the life history were noticed.

The few rough notes and figures which I possess relative to this animal would be freely put at the disposal of any one inclined to take up the study of the species.

ALBINISM IN THE ENGLISH SPARROW

ON several occasions during the past summer the writer saw a single female English sparrow (*Passer domesticus*) whose plumage was pure white. On account of the fact that the bird was seen on the busy streets of Salt Lake City, it was impossible to take it, due to the ordinance against the discharge of firearms within the city limits. The bird was observed from a distance of a very few feet and seemed to be normal in size, the beak, legs and feet were nearly the color of those of the ordinary house canary and so far as could be observed, every feather was pure white. She was always seen in company with normal members of her own species.

I have never seen any reference to albinism in the English sparrow, but, no doubt, other observers have noted it. This note is published in the hope that others who have made like observations may advise us whether or not albinism is common in the English sparrow.

THE TEACHING OF THE HISTORY OF SCIENCE

TO THE EDITOR OF SCIENCE. The communication of Professor Walter Libby on the teaching of the history of science, published in your issue of November 6, deserves more than a passing notice. The obvious importance of such teaching led one of us more than twenty-

five years ago to begin regular instruction in the subject to small classes in the Massachusetts Institute of Technology, and both of the undersigned have now been teaching the history of science in collaboration for the last ten years or more. Like Professor Libby we have keenly felt the need of a text book and *faute de mieux* have now in hand the first of two volumes entitled "Outlines of the History of Science" designed expressly for the use of our own classes. Next summer we hope to have ready Volume I dealing with the rise and progress of science and the scientific spirit to the fall of the Roman Empire. Volume II treating of the development of science in medieval and modern times should be ready a year later.

The course at the Massachusetts Institute of Technology is now an elective for all students in the third (junior) year and consists of one hour (lecture) and two hours (preparation) in the first half year and two hours (lecture) and three hours (preparation) in the second half.

SCIENTIFIC BOOKS

Paul Ehrlich. *Eine Darstellung seines Wissenschaftlichen Wirkens*. Festschrift zum 60. Geburtstag des Forschers (14 März 1914).

Mit 1 Bildnis. Gustav Fischer, Jena, 1914.

Thirty-seven authors join their efforts in this book of 668 pages to present a summary of the investigations of Paul Ehrlich. The contributions of Ehrlich himself and of his immediate coworkers only are considered primarily, and according to the bibliography (up to February 1, 1914) at the end of volume it concerns in addition to several books and monographs by Ehrlich no less than 612 separate scientific articles.

The book opens with an interesting biographical introduction by A. von Weinberg. In the gymnasium Ehrlich excelled in mathematics and Latin. In the university he early was recognized as of unusual ability and originality. While still a young medical student

he became interested in problems presented by the selective affinity of lead for certain tissues, an interest which soon extended to the problems of protoplasmic affinity in general and thus really determined the main scope and nature of his later work.

The main part of the book is divided into five sections covering different phases of Ehrlich's investigations. The first section is devoted to work that especially concerns the histology and biology of cells and tissues. Here is included Ehrlich's early work. Among the more notable results discussed in the seven articles of the section the introduction to which is by Professor Waldeyer of Berlin may be mentioned important discoveries in bacterial staining methods now in daily use every where in the working out of which Ehrlich cooperated with Koch, the microchemical differentiation of leucocytes, the demonstration of the methylene blue reaction of living tissues, and the development of new concepts of the structure and function of protoplasm (Ehrlich's *Das Sauerstoffbedürfnis des Organismus*, 1885) which form the basis of the celebrated side-chain theory advanced in the nineties to further the understanding of reactions in immunity.

The next and the largest section deals with Ehrlich's contributions to the study of immunity. It contains fifteen articles by well known workers in the field in question. The side-chain theory in the course of the proving of which so much of the work now considered was carried out is discussed by Wassermann. Of the other subjects dealt with in this section may be mentioned the technical methods employed in the investigation of immunological problems, toxins, antitoxins, and other antibodies, hypersusceptibility, and the working out under the guidance of the side-chain theory of a practical method of standardization of diphtheria antitoxin. From the reading of these articles one is deeply impressed with the great usefulness of Ehrlich's theory of the constitution and affinities of protoplasm in promoting fruitful investigation of the complex problems in chemical biology presented by the phenomena of immunity. The immu-

mediate practical results of this work are seen most clearly perhaps in the standardization of diphtheria antitoxin, as Ehrlich's method is used exclusively everywhere but the influence of the work may be said to dominate in large measure every department of investigation of immunity and every branch of the practical application of the knowledge and principles derived therefrom

The third section (three articles) considers Ehrlich's work on cancer which forms a sort of interlude between the period of intensely active investigation of problems in immunity and the latest phase of his remarkable activity, namely the development of experimental chemotherapy. The principal outcome of the work of cancer is pointed out to be the demonstration that the cancer cell increases in power of growth on passage from animal to animal, and the formulation of the view that resistance to the growth of cancer cells often observed in experimental inoculation, depends on the lack of available food particles for the cancer cells (atropic immunity).

The two remaining sections of eleven articles deal with Ehrlich's contributions to chemistry and his chemotherapy of syphilis and certain other spirochetal infections. The development through a long series of systematic biochemical experiments based on original conceptions of the affinities of cellular constituents, of a successful chemotherapy of important human infections, by direct attack on the parasites by substances specially built up for that purpose and introduced from without, is emphasized and properly so, as the logical culmination of a unique investigative activity of the highest order. Even now Ehrlich's results fully justify Huxley's prediction in 1881 that through discoveries in therapeutics it would become possible "to introduce into the economy a molecular mechanism which like a cunningly contrived torpedo shall find its way to some particular group of living elements and cause an explosion among them, leaving the rest untouched."

Most of the articles are written by men who have worked under Ehrlich and every now

and then we catch interesting glimpses of his picturesque and genial personality as well as hints to his methods of work. Naturally the many articles are not of the same merit and interest, but altogether they give us a very good and comprehensive idea of the tremendous achievements of Paul Ehrlich.

LUDVIG HEKTOEN

Infection and Resistance By DR HANS ZINSSER Professor of Bacteriology at the College of Physicians and Surgeons Columbia University New York The Macmillan Company 1914

The purpose of Dr Zinsser's book of 546 pages is to render easily accessible the knowledge that has accumulated especially from laboratory work in regard to the intimate mechanisms of infection and immunity. There are twenty-one chapters: infection and the problem of virulence; bacterial poisons, immunity in general; natural and artificial, the mechanism of natural immunity, and the phenomena following on active immunization, toxin and antitoxin, bactericidal properties of serum and cytolysis, complement fixation (two chapters), agglutination, precipitation, phagocytosis (five chapters), anaphylaxis (five chapters), therapeutic immunization in man, protective ferments, colloids. The last chapter, on colloids which is very useful in view of the many allusions in the other chapters to the analogies between colloidal reactions and the reactions between the substances concerned in the phenomena of immunity, is written by Professor Stewart W. Young. As each chapter so far as possible has been prepared as a separate unit more or less repetition could not be avoided, but as compensation there is increased clearness in the presentation of each subject. We are told in the preface that the book is intended primarily for the undergraduate medical student, and the author replies to anticipated criticism of his treatment as being too difficult and too technical for the student by saying that his experience in teaching does not indicate such to be the case. Herein the reviewer is inclined to agree with

the author but at the same time it must be said that more attention has been given to the details of certain controversies and experiments now largely of historical interest only than might be regarded as required in a book like this. This fondness for detail however does not detract seriously from the usefulness of the book to student and practitioner. The references to original sources are very abundant and will prove of great help but they are not given according to any accepted bibliographic standard the page being omitted in most cases. There are altogether but very few books that attempt to give a comprehensive summary of immunological knowledge of the same general scope as this one by Dr Zinsser but their number is increasing for the present Dr Zinsser's is the most serviceable.

LUDVIG HILKOTEN

The Norwegian Aurora Polar expedition 1902-03 Vol I On the Cause of Magnetic Storms and the Origin of Terrestrial Magnetism By KR BIRKELAND Second Section Christiania H Aschehoug & Co 1913 4° Pp x+319 801 with many maps and plates

Five years have elapsed since the publication of the first section of the present work yet in spite of incessant labor this second section could not be sooner completed. This was due to the great number and variety of the computations and experiments necessary. The author considers that the results attained by the investigation of conditions during positive and negative Polar storms and particularly the diurnal motion of the respective magnetic storm centers are so valuable as to fully compensate for the exertions and personal sacrifices that the work has cost.

In order to make it clear whether his conclusions from widely spread observations in different parts of the world could be harmonized with his previous theoretic assumptions, he has carried out a long series of experiments with a "terrella" or magnetic globe suspended in a large vacuum box intended for electrical discharges. He has thus been able

to obtain photographic representation of the way in which cathode rays move singly and group themselves in crowds about such a magnetic globe. Special study has been made of these groups of rays which produce magnetic effects analogous to those observed upon the earth during positive and negative magnetic polar storms. The photographic plates of these experiments are veritably fascinating.

The author holds that he has demonstrated that the magnetic storms on the earth polar and equatorial may be assumed to have as their primary cause the precipitation toward the earth of heliocathode rays of which the magnetic rigidity is so great that the product $H\rho$ for them is usually about 3×10^6 C.G.S. units. He discusses the objections raised to this theory by Schuster and Hale and states that the experiments which were originally intended to procure analogies capable of explaining terrestrial phenomena such as the Aurora and magnetic storms were afterward continued to derive information in regard to the conditions under which the emission of the assumed heliocathode rays from the sun might be supposed to take place. The terrella was made the cathode in the vacuum chamber and experiments carried on for many years. In this research there gradually appeared experimental analogies to various cosmic phenomena such as zodiacal light, Saturn's rings, sun spots and spiral nebulae. Whatever be the fate of the author's hypotheses the facts recorded in this work are well worthy the careful study of those interested in electromagnetism.

W H DALL

Physics of the Household By CARLTON JOHN LYNDE Macdonall College Canada 1914 12mo Cloth Pp 313

Professor Lynde's book indicates that the author believes in teaching physics by consulting and describing first the student's own environment in information experiences and appliances. These things are the fundamentals of this book. The reasons assigned in the preface for the teaching of physics to young students are: First that they may ob-

tain knowledge of the physical world about them, and second that they may gain through this knowledge the power to control the forces of nature for their own benefit and for the benefit of others. In other words, we wish them to acquire knowledge which they will use in every day life.

This work with other recent publications from a similar point of view represents a reaction against the prevailing formal text books and formal treatment for beginners in the study of science. Those who consider fundamental things in physics to be the laws and generalization of the science will, perhaps feel that the traditional logical development is very much neglected at some points. On the other hand there is a growing demand among experienced teachers and critics of educational efficiency for a readjustment of textbook treatment. Where the strictly logical conflicts with what is considered profitable educational procedure the tendency is to defer logical organization of subject matter till later. Experienced teachers, critics of education and the general public are demanding less drill work in abstraction and more practical work dealing with experiences and appliances such as one encounters in the world of reality. Lynde's book is a valuable contribution to the problem of teaching physics in a more practical way.

The first two chapters deal with a multitude of familiar mechanical contrivances with discussions of the lever principle and other simple machines. This reminds one of the popular old text books on natural philosophy of fifty or seventy five years ago and it is an altogether desirable revival. The chapter on mechanics of liquids is introduced with discussion of a city water supply, water supply for country homes, wells, etc. Following a chapter dealing with atmospheric pressure a variety of air appliances are discussed including pumps, the pneumatic tank system of water supply for homes, the hydraulic ram, the air pump types of vacuum cleaners, the fire extinguisher, the siphon, the trap, the gas meter, etc. In the chapters on heat a similar list of important familiar appliances are to be

found. As a rule the author presents a descriptive treatment of a series of practical physical situations in order to form a basis for discussion of the principles involved.

The chapters on electricity, light and sound follow more closely the customary treatment and contain less of the distinctive feature of the first half of the book. For the sake of consistency in the general plan there is much material of a practical and illustrative nature that should have been incorporated in these latter chapters. It is somewhat disappointing to find a commendable book with so many amateurish free-hand drawings.

F F Good

TEACHERS COLLEGE
COLUMBIA UNIVERSITY

THE FORSYTH DENTAL INFIRMARY FOR CHILDREN

THIS Boston institution pioneer among charities for the adequate care of the mouths and throats of the children poor or rich of a large city was dedicated formally by the Governor and others on Tuesday November 24 and began its actual work the first of December. It is in the form of a splendid memorial erected by Thomas Alexander Forsyth and John Hamilton Forsyth to their brothers James Bennett Forsyth and George Henry Forsyth of whom however at present only the first named is living. The amount already provided for this important work it is understood, in the building and in endowment is well along toward three millions of dollars.

Beautiful bas-relief bronze doors ("The Mother giver of life and love" and "The Commonwealth giver of health and learning") by Roger Noble Burnham, a bronze bust of James Forsyth by Bela Pratt and one of George Forsyth by Mr Burnham and charming Dutch and American tiling of elaborate design (A H Hepburn) are perhaps chief among the internal works of art of the beautiful white marble building situated on The Fenway north of the Museum of Fine Arts although bronze doors ("Uncle Remus" "Br'er Rabbit" "Alice in Wonderland" etc.), also ornament the entrance way for the chil-

dren patients from Forsyth Park on the north. The land on the south side of the hospital is also to be parked by the city.

The therapeutic and surgical outfit of this perfectly fire proof infirmary may not be adequately described in this place. Suffice it that its present means for caring for six hundred patients a day are the most timely and complete that expert technical thought and information served with unlimited funds could provide so that several features wholly new have their place in this institution. The sixty eight (at present) dental chairs for example in the great operating room are the most elaborate ever constructed for each has running water warmed to suit the requirements of a tooth cavity compressed air air suction electricity an electric signal system etc while many of them are equipped with the most recent of anesthesia mechanisms all are finished throughout in white enameled metal in line with modern ideas toward asepsis. The dental instruments which have been used for a patient are enclosed in a flat covered metallic tray and sent to the sterilizing room where each night they are in tiers subjected to dry heat at 300° F in gas thermostatically controlled ovens. This careful system of asepsis will require the daily use of a thousand sets of dental instruments when the number of chairs has been increased to the capacity of the Infirmary.

The arrangements for amusing the children while awaiting their unpleasant experiences in the dental chairs or in the nose and throat department (which is very elaborate and complete) are a noteworthy part of this institution quite in line with modern medical principles of good humor and the related esthetic index. The little patients (none over sixteen) have a large room known as the Children's Room close to their special entrance which is quite after their own youthful hearts. Miss Tower a skilled kindergartner here makes it her sole business to see to it that the children forget for the time why they are come hither and the approaching disagreeable duty of having one's teeth put in order or one's throat treated. Here for example is an

alluring aquarium nine feet long and three feet square two thirds of which is for graceful plants and a few score of our more interesting native fish in large variety while one third is a reptile tank so built and arranged as to at once display and make comfortable all manner of American amphibious little beasts. Here too is a library of story books games etc and later on there will be other things as actual experience shows their need. Around the walls of this children's room are extremely elaborate friezes of Delft tiling illustrating some familiar fairy stories—Oliver Wendell Holmes's 'Dorchester Giant' 'Rip Van Winkle' Hawthorne's 'Golden Pheasant' and Mrs Prescott Peabody's 'Pied Piper'.

Connected with the Children's Room is a metallic cloakroom so constructed that its entire contents can be fumigated and thus sterilized at night electric pumps forcing in and removing the respective atmospheres at the instigation respectively of two push buttons. The plumbing everywhere is extensive and to some extent original and unique. There is a small ward for the girls who may chance to need its care and a like one for the boys and there is of course a small but adequate amphitheater for the professional study of oral or of nose or throat operations and a large research laboratory there is much museum space a library and a lecture room that will seat about three hundred persons.

In addition to a large number of routine operating dentists (some of whom work full time and others half time or third time) the following at present constitute the staff of the Forsyth Infirmary: Director Dr Harold De Witt Cross assistant to the director William Z Hill nose and throat department William F Cheney consulting otologist Edgar M Holmes extracting staff Edward V Bulger and eleven others. X-ray department Arl W George consultant F Albert Kinley Jr consulting surgeons Fred B Lund Harry H Germain Hugh Cabot and Hugh Williams consulting physiologist George V N Dearborn oral surgeons Albert Midgley Harry B Shuman Leroy M S Miner and B H Strout orthodontia Frank A Delabarre,

head of department, consulting orthodontists, George C Ainsworth, Alfred Rogers and Lawrence W Baker, assistants, Arthur L Morse, Harry W Perkins, Ernest W Gates and Norman G Reoch

The trustees of the institution besides Thomas Alexander Forsyth, Director Cross and John Francis Dowsley the president of the State Board of Registration in Dentistry, are Edwin Hamlin, Chester Bradley Humphrey, Edward Walter Branigan (deceased), Harold Williams, Timothy Leary Gordon Robert McKay, Erwin Arthur Johnson and Nelson Curtis. There is a good work well begun
G V N D

FIRST EXPLORATION OF AN ALASKAN GLACIER

THE first exploration of the Harvard Glacier and the continuation of the observations of previous scientific expeditions in regard to the great glaciers of Prince William Sound, Alaska have resulted from a field expedition recently completed by Miss Dora Keen, of Philadelphia, with the aid of three men

Leaving Valdez Alaska on August 15, 1914, in a small launch the party was set down next day near the head of College Fjord with six weeks' outfit and two small boats to one of which a detachable motor was affixed. The object of the expedition was twofold (1) to explore the sources of the Harvard Glacier in the unmapped section of the Chugach Mountains. If a pass were found, it was planned to cross the divide and return to tidewater down the Matanuska Glacier and the Valley trail of the same name—a traverse of some 50 miles of snow and ice, almost entirely without timber, and a succeeding 100 miles of a hard trail chiefly through uninhabited country (2) To continue the observations of the changes taking place in the glaciers of College Fjord and Harriman Fjord by means of photographs taken from lettered stations variously occupied since 1899 by the Harriman Expedition, U S Geological Survey, and the National Geographic Society's Expeditions. Both of these objects were accomplished, in spite of

almost constant rain or snow, during an expedition that lasted six and a half weeks actually in the field

The expedition was a private one, but undertaken at the suggestion and under the guidance of the junior leader of the National Geographic Society's Expeditions, Professor Lawrence Martin of the University of Wisconsin. The party consisted of Miss Keen, leader, whose previous experience had been on the glaciers of the Alps and in two extended expeditions in Alaska, entirely on the glaciers of the Wrangell Mountains and resulting in the first ascent of Mt. Blackburn, 10 140 ft., Mr. G. W. Handy of McCarthy Alaska who had been responsible for the success of her second attempt on Mt. Blackburn, G. A. Rabehl, also an old timer in Alaska, and Mr. H. L. Tucker, of Boston topographer whose previous experience had been on the 1910 Parker Browne Expedition to Mt. McKinley and with the Yale Peruvian Expedition on Coropuna, 21,000 feet

Exploration of the Harvard Glacier

The Harvard Glacier has a tidal ice cliff a mile and a quarter wide and 350 ft. high, from which ice breaks constantly in summer, causing danger to small boats. Still, a landing was effected in safety on one side and supplies gradually relayed to a point seven miles from the face where the ice was at last smooth enough to make travel on the glacier itself possible. Over another nine miles of crevasses the party succeeded in reaching the sources of the glacier, to a point where further progress was impossible even on snowshoes, because of the shattered condition of the glaciers flowing from the steep divide. No pass being found, the return was made from this point, by the same route. All the way, food, tents etc., and for most of the distance fuel, had to be relayed on the backs of the party, and all the going was hard, so that three and a half weeks were spent in reaching an altitude of 6,100 feet, sixteen miles from the face of the ice

Danger from snow slides also prevented any high ascent, but data of value were secured

from which the first map of the region will be prepared. Observations of snowfall and temperatures will also throw light on the almentation of the glacier and its many tributaries.

Photographs of the Glaciers of Prince William Sound

Observations of some 20 glaciers in College Fjord Harriman Fjord and Columbia Bay constituted the second part of the work which is a continuance of the study of the advance and recession of these glaciers with a view to determining their causes. Some glaciers appear to have receded as much as a quarter of a mile in a year while others near by seem to have advanced as great an amount.

In spite of great difficulty and some risk in forcing a frail row boat through solid jams of icebergs which threatened to crush it this part of the expedition also was accomplished without accident.

SPECIAL ARTICLES

AN EARLY OBSERVATION ON THE RED SUNFLOWER

UNTIL the present month (November 1914) I supposed that the red sunflower found at Boulder was the first of its kind ever seen by a botanist. I have however recently learned from Dr David Griffiths of the U S Department of Agriculture that as long ago as 1892 he found a few plants of the wild annual sunflower on the Missouri River bottom in Potter County South Dakota having the rays marked at the base with maroon about the same color as is seen in the dark forms of *Lepachys*. Again in 1897 he saw in the Sundance region of Wyoming (probably within 16 or 20 miles of Sundance) a single plant having the rays maroon with only a narrow fringe of yellow. Dr Griffiths discussed the matter with Mr T A Williams who had also seen a plant somewhere he thinks in the Bad Lands of South Dakota. It thus appears that the red sunflower has arisen independently as a "sport" in at least three widely separated places a fact which may have a certain bearing on the suggestions of Professor Bateson regarding its nature. It is to be noted that the two cases reported by Dr Griffiths represent

different subvarieties both different from the original Boulder one.

In *Botanical Gazette* October 1914 Professor E C Jeffrey has a very interesting article on the relation between hybridism and imperfection of pollen.¹ The various forms of red sunflowers which have been developed for horticultural purposes result from crossing the original wild sport of *Helianthus lenticularis* with various garden forms ascribed to *H. annuus*. Speaking broadly these crosses in all directions and through several generations have been perfectly fertile at least in the sense that they have produced abundant seed. Deficiency of pollen has however been common especially in dark red varieties and doubles. My wife who made the crosses was sometimes unable to get pollen from some of the most beautiful plants though she could obtain seed from these by using pollen from others. According to Dr Jeffrey's criteria this might seem to indicate that *H. lenticularis* and *annuus* are distinct species although in this case it seems nearly certain the species *annuus* arose in cultivation. It is possible of course, that the prairie sunflower *H. lenticularis* is a mixture of more or less different things. Thus we obtain seed of the wild Californian form which appeared to be true *lenticularis* but had the physiological peculiarity of remaining in flower after the Colorado plants were over. If however the present red sunflower of horticulture is in any sense a crypt hybrid it certainly presents a very different case from the hybrids between it and the undoubtedly distinct species *H. cucumerifolius*. These latter hybrids of various kinds according to the particular varieties used are some of them very attractive. They can be produced in quantity as F_1 plants but so far it has proved impracticable to get enough F_2 seed for horticultural purposes. The behavior here is much more like that usually expected of hybrids.

¹ With regard to *Sorbus* which is specially cited by Dr Jeffrey in illustration of his theory it is to be noted that this genus was apparently producing hybrids in Miocene times. (*Amer Jour Science* Jan 1910 p 76)

A paper by Dr G H Shull² on the apparent independence in inheritance of the stem and bud colors (anthocyan) in *Fuchsia* suggests a reference to the condition found in the new garden sunflower with wine red on the rays. The more usual red (chestnut red & e red on orange) variety can nearly always be recognized in the seedling stage by the dark purple stems a fact of utility in horticultural practice. To our surprise when we came to raise the wine red (red on primrose yellow) form in quantity we found that the purple-stem character failed in spite of the fact that the history of the plant indicated that it differed from the other red one in the yellow background not at all in the anthocyan factor. Mr Leonard Sutton who grew the wine red variety in England from our seed also reports 'It is a remarkable fact as you mention that the purplish color is not shown in the stems of this new variety'.³ The question naturally arises whether in such a case it is necessary to assume a splitting or complexity of the factor representing anthocyanin whether it is not equally possible that some condition has arisen controlling the expression of the factor for red that factor remaining genetically the same. In the course of breeding plants, we are doubtless too apt to assume that our recorded data represent the whole of the pertinent facts. It is evident that any given plant represents in addition to the known 'units' an assemblage of others which are unknown & merely suspected while the known ones may have unknown properties. Thus in spite of records and observations the stage may be invaded at any moment by unnoticed *dramatis personae* and the development of the plot may belie the promise of the first acts.

A REMARKABLE MICROSAUR FROM THE COAL MEASURES OF OHIO

THE Amphibia of the American Coal Measures as now known are represented by eighty eight species representing seventeen families

² *Journal of Genetics* June 1914

³ *Letter of September 1914*

and five orders. All of the species of *Branchiosauria* and all of the hitherto recognized *Microsauria* are uniform in the absence of an osseous carpus and tarsus. It is thus with considerable interest that we find an osseous tarsus in a microsaurian species from Linton Ohio. The species was described many years ago by Cope¹ and it has not since been studied until Professor Grabau recently forwarded the type specimen to me from Columbia University where it forms a part of the geological collections.

Ichthyocanthus platypus referred by Cope to the Permian genus *Fryxops* is a small microsauro which in life probably did not attain a length of more than eight inches but was of a very active nature as seems to be indicated by the scanty remains preserved which consist of the posterior half of the body.

At first glance the specimen recalls a reptile, such as *Eosaurus* Cope. Will but closer examination reveals remarkable differences. The femur in its well ossified condition and the high degree of development of the trochanters is typically reptilian and there is nothing strikingly amphibian in the tibia and fibula. The tarsus however is reptilian with its central and the distal row being composed of five elements. All of the elements are well ossified and articulate with phalanges which have a typical amphibian arrangement with the formula 2-2-3-3-2. The sharply clawed ungual phalanges add to the animal nature of the species.

The recognition of the exact nature of this species adds considerably to our knowledge of the diversity of structure among the Coal Measure Amphibia. Environmental conditions prior to the Coal Measures had effected a wide diversity of structure within the group. So early in the geologic history of the land vertebrates as the Pennsylvanian the Amphibia had assumed a variety of forms which had specialized into strictly aquatic, terrestrial, subterranean and arboreal. Specialization had extended to the loss of limbs, ribs and

¹ Cope F D 1877 *Proc Amer Phil Soc*, p. 574 1888, *Trans Amer Phil Soc*, p. 289, Fig 1

ventral armature in a few species and to the acquirement of claws, running legs or a long propelling tail with expanded neural and hemal arches in others. This wide diversity of structure is intensified by the recognition of *Ichthyosaurus platypus* as a microsauro with an osseous tarsus serving to confuse still further our hazy ideas of amphibian phylogenesis.

A full description with illustrations will be given of this interesting form in another place.

THE OHIO ACADEMY OF SCIENCE

THE twenty-fourth annual meeting of the Ohio Academy of Science was held at Ohio State University, Columbus, Ohio, on November 26, 27 and 28, 1914, under the presidency of Dr. F. C. Mendenhall, of Ravenna.

The address of the president was delivered Friday evening, on the subject 'Some Pioneers of Science in Ohio', and on Saturday morning the academy listened to a very timely lecture upon 'Foot and Mouth Disease' by Dean D. S. White of the College of Veterinary Medicine of Ohio State University.

The trustees of the research fund announced a further gift of \$250 from Mr. Emerson McMillin of New York for the encouragement of the research work of the academy.

In accordance with the report of a committee appointed a year ago, the academy voted to deposit the library of the academy with the library of Ohio State University—an arrangement which may be terminated by either party on suitable notice.

The matter of the celebration of the annual meeting of 1915 as a quarter centennial anniversary was referred to the executive committee.

Twenty-three new members were elected, making the total membership of the academy two hundred and fifty-four.

The officers of the academy for the year 1914-1915 are as follows:

President—Professor J. Warren Smith, Ohio State University and Ohio Section U. S. Weather Bureau.

Vice presidents—(Zoology) Professor F. C. Waite, Western Reserve University (Botany)

Professor F. O. Grover, Oberlin College, (Geology) Professor C. G. Shatzer, Wittenberg College, (Physics) Professor J. A. Culler, Miami University.

Secretary—Professor L. L. Rice, Ohio Wesleyan University.

Treasurer—Professor J. S. Hine, Ohio State University.

Librarian—Professor W. C. Mills, Ohio State University.

Executive Committee, together with the president, secretary and treasurer, members ex officio—Professor C. D. Coons, Denison University, Professor T. M. Hills, Ohio State University.

Board of Trustees of the Research Fund—Professor W. R. Lazenby, Ohio State University, Professor M. M. Metcalf, Oberlin College, Professor N. M. Fenneman, University of Cincinnati.

Publication Committee—Professor J. H. Schaffner, Ohio State University, Professor C. H. Lake Hamilton, Professor I. B. Walton, Kenyon College.

The complete scientific program follows:

Presidential Address—'Some Pioneers of Science in Ohio,' Dr. F. C. Mendenhall.

Lecture, 'The Foot and Mouth Disease,' Dean D. S. White, College of Veterinary Medicine, Ohio State University.

Papers

Efficacy of Lightning Rods, J. Warren Smith.

'Thunderbolt from Whitecliff Bay,' Katharine Doris Sharp.

'A Preliminary Survey of Plant Distribution in Ohio,' John H. Schaffner.

'Akron Fishbait Industry,' Chas. P. Fox.

'The Physiographic Provinces which meet in Ohio,' N. M. Fenneman.

'Color and Coat Inheritance in Guinea Pigs,' W. M. Barrows.

'Note on a New Nematode Parasite of Cryptobranchus,' F. H. Kreeker.

'Prediction of Minimum Temperatures for Frost Protection,' J. Warren Smith.

'Is a Dry Summer and Autumn Apt to be Followed by a Wet Winter and Spring with Possible Floods?' J. Warren Smith.

'Comparative Rate of Growth of Certain Timber Trees,' William R. Lazenby.

'Inheritance of Taillessness in the Cat,' W. M. Barrows and C. A. Reese.

'The Cause of Milk Sickness and Trembles,' F. L. Moseley.

THE WAR AND THE CHEMICAL INDUSTRY¹

PHILADELPHIA was the cradle of chemistry in this country. What was possibly the first chemical society in the world was founded here in 1792. A few years later one of its members addressing the society said

The only true basis on which the independence of our country can rest is agriculture and manufactures. To the promotion of these nothing tends in a higher degree than chemistry. It is this science which teaches man how to correct the bad qualities of the soil he cultivates by a proper application of the various species of manure, and it is by means of a knowledge of this science that he is enabled to pursue the metals through the various forms they put on in the earth separate them from substances which render them useless, and at length manufacture them into various forms for use and ornament as we see them. If such are the effects of chemistry how much should the wish for its promotion be excited in the heart of every American! It is to a general diffusion of knowledge of this science next to the virtue of our countrymen, that we are to look for the firm establishment of our independence. And may your endeavors, gentlemen, in this cause, entitle you to the gratitude of your fellow citizens.

Considering the time when these words were spoken, we must marvel at the vision of the future which must have illumined the mind of the speaker. If in the last clause quoted he had said "ladies and gentlemen" it would have been complete.

But Philadelphia was also the cradle of the chemical industry in this country, and up to the present day occupies a very important part of that field. Some of the pleasantest recollections of my earlier life

¹ Address complimentary to the citizens of Philadelphia given by Dr Wm H Nichols at the Philadelphia Meeting of the American Association for the Advancement of Science.

are associated with those fine men then prominent here but now mostly passed on who made this city respected wherever chemical products were concerned and not an insignificant part of my youthful enthusiasm was imbibed from them

Therefore when I was asked to talk to you on the subject of the war and the chemical industry I accepted with the hope that I might add something to the general knowledge on the subject and in a modest way pay a portion of an old debt. In the interval which has elapsed however the ground has been covered by many men on many occasions and I find myself in the position of talking to you on a subject as well understood by most of you as it is by myself. There may be certain phases however which will repay further thought and possibly there may be deductions worth considering. I shall therefore ask your indulgence if I ramble somewhat and talk largely about what we have not done avoiding dry statistics as far as possible.

Some of us may be old enough to remember our own civil war. Most of us remember the so-called Spanish war. Any knowledge or experience gained from these wars intimate as the former was gives no data on which to base any calculation as to the world-wide results of the present devastating struggle. Even our imaginations are unable to satisfy our judgments which are more or less consciously or unconsciously influenced by our point of view. It is simply impossible to forecast the results industrial, geographical or moral. The world has never seen anything like it before and therefore reasoning from analogy is entirely out of the question. We know this however that where such an enormous number of men are withdrawn from ordinary pursuits many never to return and such incalculable damage is done to property the world must feel for

many years to come the effects which this impoverishment must produce. We might just as well accustom ourselves to the thought that before us lie years of painful toil and reconstruction so that prudence that great virtue of our forebears may become more and more a part of us and drive out the vice of extravagance which has become such a prominent characteristic of our people.

Judging from what we read in the papers we might conclude that the chemical industry in the United States is in an infantile condition and hardly worthy of serious consideration. Those not acquainted with the subject are ready to admit without argument that almost any European country is far and away ahead of us in volume and ability to produce economically. A glance at the 13th United States census will dispel at least some of these views and is well worth taking. It includes under the heading chemicals and allied products nine principal divisions and gives the value of the output of each.

1 Paint and varnish	\$125 000 000
2 Chemicals (general)	117 000 000
3 Fertilizers	104 000 000
4 Explosives	40 000 000
5 Dyestuffs and extracts	16 000 000
6 Sulphuric nitric and mixed acids	10 000 000
7 Wood (except rosin and turpentine)	10 000 000
8 Essential oils	2 000 000
9 Bone carbon and lamp black	2 000 000

The above values were produced by 2 140 establishments having a capital of \$483 000 000 and employing 88 000 persons. The census does not state however what is probably the fact that the United States produces more sulphuric acid by catalysis than any other country in the world and possibly more than all other countries combined. This fact has a bearing on what will be alluded to later namely the possible manufacture of coal tar dyes and other products for which fuming sulphuric acid is often an absolute necessity.

The census furthermore shows that the return on capital invested in the chemical and allied industries is not so great as in other branches of manufacturing endeavor. This is due to the high initial cost of plant, frequent alterations and reconstructions made necessary by the advance of knowledge and I imagine by a somewhat senseless competition which has seemed to affect chemical manufacturers for as long as I can remember.

Owing to the enormous territory covered the conditions governing the industry are quite different from those existing in other countries. Like all industries the greatest economies can be practised in the largest units, but this fact of extensive territory which is served makes numerous small units necessary. The products usually are bulky and low priced and rail road freights play an important part in the problem. This fact must be borne in mind constantly when comparing the industry in this country with that in any other.

We Americans are apt to pride ourselves on the progress which we have made along manufacturing lines and take to ourselves great credit for what has been accomplished. In view of the enormous supply of various raw materials which this country has at its disposal an analysis of what we have done I fear would show that instead of taking undue credit to ourselves we should be very humble because we have not done much better. Of course I realize that this is a comparatively new country, and that it took time to get things into working order. Lines of communication had to be constructed, factories had to be built and rebuilt and all the necessary impedimenta of industry had to be evolved from a condition which at the time the Philadelphia chemist quoted in the beginning spoke consisted of little more than

forests, prairies and prospects of mines. If during this period of development a good deal of waste occurred and a number of abuses crept in it is not so much to be wondered at. We have however arrived at a period when it is borne in upon us from all sides that conservation of natural resources as well as human energy is absolutely essential if we are to go forward with anything like the strength and certainty to which our resources entitle us.

Of raw materials for the chemical industry without going into unnecessary voluminous details we have an abundance—cheap phosphate, rock salt, copper, sulphur, coal, wood, bauxite, zinc. In addition to raw materials and among our most valuable assets are our college professors of chemistry who I am sure could if called upon render additional priceless service to the lasting benefit of the world and of themselves.

On the other hand we must import much of our sulphur in the form of pyrites, nearly all of our potash, all of our tin, nickel and nitrate of soda. We have large supplies of nitrogen available from animals and coal. But the great supply of the future is still in the air. This source of supply however has up to the present time proved rather difficult of access. Of course it must be secured, but just how is not altogether clear in spite of the good work already accomplished. This is one of the problems which the chemist, chemical engineer and electrical engineer must solve, however, within a comparatively few years as the nitrate beds of Chili while still very large will some time come to an end.

With the Allies in command of the sea the war has not affected any of these raw materials very greatly except potash. This salt is widely enough disseminated in various forms in this country but where of hopeful strength it is inaccessible and

where accessible it can not be produced without expensive plant construction which would probably be useless as soon as the German supply is once more obtainable. In arriving at this conclusion due note must be made of the German costs and not of the German selling prices. The Stassfurt salts can be produced very cheaply indeed, and the price which they have been able to bring in the markets of the world have yielded an enormous profit. This fact, of course, is a determining one when we talk of producing our own potash.

One of the most important of the chemical industries is the manufacture of fertilizers for the soil. We have in this country enormous deposits of phosphate rock easily accessible and cheaply mined. This rock has been exported in large quantities to Europe and the Orient and is in sufficient quantity to last a number of years even in the careless way in which it has been used. A complete fertilizer however, requires potash and as noted above we have been in the habit for a number of years of getting our potash from Germany and there is every reason to expect that we will continue to do so for many years to come. If, as one of the results of the war while it lasts, enough potash can not be obtained to make the fertilizers to which we have been accustomed, I feel that this will not be an absolutely hopeless misfortune. It is quite possible that the propaganda for the use of potash has been carried too far and that less could be used on the soil without any great disadvantage. At any rate we will be quite able to furnish an abundance of fertilizers in this country containing phosphoric acid and nitrogen, and if for a while we have to rely more or less upon the soil to furnish its own potash, I imagine we will not suffer beyond redemption. From some quarters in the south and elsewhere I have heard rumors

that a smaller cotton crop would be looked upon as a blessing, and it is quite likely that without government or other assistance the natural laws of supply and demand will produce a smaller crop next year, simply because there may not be enough potash to supply the requirements of a large one.

With here and there an exception, the only effect the war has had upon the chemical industry is the effect which it has had upon those industries which consume its output and I think this can be taken as a general statement covering all articles. Of course there are notable exceptions, such as smokeless powder and other products required for war purposes.

Some heavy chemicals, the receipt of raw material for which has been very much curtailed or stopped altogether, have advanced sharply in value but generally speaking the chemical industry has not profited by advanced prices as a result of the war. Owing to reduced home consumption, the result in some cases has been a great falling off in profit a condition which I trust will not be of long duration. I am a believer that the manufacturing industries of this country will before very long be on the up grade and all of the chemicals produced, speaking generally, will be needed.

More has been talked and printed lately about a portion of the chemical industry which has not taken very deep root in this country, than about all the rest of the industry put together. I refer to the organic chemicals resulting from products of the distillation of coal tar. Many have wondered why the American chemist has not stepped up and taken the place of the foreign manufacturer in supplying the textile and other industries with colors, evidently not understanding the size and complexity of the question. I think it worth while, there-

fore, to discuss this at some length, as it is probably the most pressing question before the chemical world in this country to day and I fear the one least likely to receive a favorable reply. A few years ago every coke oven in this country was what is known as a bee hive oven, and all the by-products of the distillation of coal were lost. It is only in comparatively recent years that by-product furnaces have been constructed and various by-products saved. The ammonia was naturally first utilized and the products of the distillation of tar have been among the last. In fact, a theory existed in the minds of many people that the tar produced by American coal did not possess the necessary constituents to make it useful as a basis for the production of organic chemicals. I have been myself told by one of the large producers in Germany that it was absolutely certain that American coal did not possess the necessary qualities. The object of this information was probably to put out of my mind any latent ambition along forbidden lines, but as it was given by the commercial manager and not by one of the scientific staff I believed him, but wondered if it were true.

In a lecture delivered to the board of directors of the General Chemical Company on October 23, 1914, the subject and its difficulties were outlined by Dr. B. C. Hesse. Owing to the immensity of the subject only a small part of it was treated. This able lecture has since been published in the *Journal of Industrial Chemistry*, but I can not do better than quote from it freely, as I consider it the best exposition of the case that has come to my attention. He says:

At the very beginning it should be pointed out that the world's market in coal tar dyes, as it stands to day, comprises, in round numbers, 900 distinct and different chemical substances which

are made by the aid of 300 products of transformation, themselves not dyes, of 10 products obtained or obtainable from coal tar by distillation, refrigeration, expression or the like. Therefore, actually and in reality the present coal tar dye industry comprises no fewer than 1,200 different products and as many or more different processes of manufacture and requires many hundred different sets of apparatus of varying capacity and of different kind for many hundred different operations. A manufacturing problem comprising so many independent and yet interlaced units of manufacture and production has therefore within it many elements of complexity.

World's figures are not available. The fullest, best most dependable and most recent figures are those dealing with Germany. In the year 1913 the total export value of Germany's coal tar industry including dyes and products of chemical transformation or intermediates, amounted to \$55,264,522 distributed over 33 countries and shared in by 22 factories, on June 30, 1912, 21 of these factories had a combined capitalization of \$36,700,000 and declared and paid dividends of \$11,600,000 or 21.74 per cent of the capitalization, for that year.

Of the 5,369 active corporations in Germany on June 30, 1912 1,004 or 18.69 per cent are divided into 19 groups of the chemical and allied industries. Arranged in the order of their income producing effects these 19 groups are, in part, as follows:

	Per Cent	No. of Corporations
Coal tar dyes	21.74	21
Metallurgy	11.75	61
Soaps and candles	11.65	21
Glass	11.61	39
Heavy chemicals	11.51	104
Explosives	11.22	28

The remainder range between 5 per cent and 10 per cent except mining which is at the foot of the list with 0.51 per cent return.

Therefore, any attempt to take away coal tar dye business from Germany means attacking the best equipped and the best income producer of Germany's entire chemical and allied industry.

Dr. Hesse estimates as follows on the entire world production:

Germany	\$63,222,846
Great Britain	5,982,675
Switzerland	6,452,651
France	5,000,000
United States	3,750,000
	\$89,408,172

with Russia, Holland, Austria and Belgium to be added. Allowing \$10,000,000 for these, which is clearly very high, it makes the absolute maximum production all over the world substantially \$100,000,000.

The development of the coal-tar dye industry called for 8,062 German patents in the years 1876-1912 or 224 per year; corresponding patents have been taken out in other countries, *e. g.*, 2,432 in the United States.

But it is authoritatively said that only 1 in 100 of the German patents is a money maker, and as a matter of fact, in the case of the 921 dyes in the world markets at the end of 1912, only 485 U. S. patents and 762 German patents were involved or 19.91 per cent. of the total U. S. and 9.46 per cent. of the total German patents. Of these 921 dyes 50 per cent. were never patented in the United States, the U. S. patents on 26 per cent. have now expired, leaving 24 per cent. still covered by existing U. S. patents and many of those expiring in 1915.

Broadly speaking, the entire coal-tar dye industry is a complicated maze and network of interlocking and interlacing products and by-products; these are great in number but, in most cases, small in volume individually. In numerous instances the very existence of the by-products was the sole directing cause for the invention of new dyes and classes of dyes.

The average annual unit gross per year of the 900 coal-tar dyes, exclusive of alizarin and indigo, all over the world outside of Germany has previously been shown to be about \$11,000. Add to this fact the interlocked and interlaced dependence of intermediates and finished dyes, further that the German works have long ago fully paid for their plant, their experience and their sales organization and the result is what seems to be a complete answer why Germany controls the world's coal-tar dye market. In fact, the whole industry, taking everything into account, is just about a one nation business. It is a business made up of a large number of small units and all units essential to success.

Germany has this business established in 33 other countries; it is evident that any country starting in now would be greatly handicapped thereby if it attempted to enter the race for the full distance.

Although Germany has relied upon Great Britain for its crudes, *i. e.*, its benzol, its toluol, its naph-

thalene and its anthracene up to the middle of the '90's, and perhaps later, yet England has not been able to make any headway, but on the contrary has always lost ground. Many of these non patented world's dyes are also non patented in England, yet most of Great Britain's requirements of those materials have always been supplied by Germany.

The answer to the question as to why Great Britain has not succeeded against Germany can not be that Great Britain is not a nation with highly developed chemical industries. A German chemist as well equipped as any other living man to express an opinion and to compare German industries with British industries has said the following:

"To be sure, we know that several of the European countries, *e. g.*, England, are still ahead of us in many branches of the chemical industry, especially in inorganic manufacture. But in no country on earth are those branches of the chemical industry which demand versatility of thought, and particularly a large body of scientifically trained employees, so well developed as with us. Our synthetic dye, synthetic drug, and perfumery industries are foremost throughout the world, and there is probably no country in which the heads of factories are so imbued with the conviction that their employees must needs cast a glance beyond domestic boundaries."

Each one of the large chemical manufacturing countries of Europe, without exception, buys more intermediate products from Germany than it sells to Germany and all of the countries but one, namely, Switzerland, buy more dyestuffs from Germany than they sell to Germany. In other words, and broadly speaking, all the rest of the world, outside of Germany, merely assembles intermediates purchased from Germany, into finished dyes; Germany alone makes all its own intermediates; that is, Germany makes all the dye-parts and the rest of the world assembles these dye parts into finished dyes. Needless to say, the one who controls the manufacture of dye-parts actually controls the manufacture of dyes.

Where Austria, Belgium, France, Great Britain, Italy, Russia and Switzerland singly and combined have failed, in spite of their large other chemical industries, to take away this business from Germany, the American chemist should not be blamed nor found fault with because he has not succeeded, nor should it be assumed that transplanting of the whole industry can be done at once and is a perfectly easy thing to do, as so many seem to think. The transplanting of that industry

out of Germany is an undertaking properly and fitly to be described as titanic.

Why the other countries have failed is probably due to the fact that they contributed little or nothing to the real upbuilding of the business and to its creation, for the coal tar dye business is a created business, those who aided in its creation were in a position first to reap the benefits—an advantage they have no doubt earned and deserved through the effort they expended and the risks they assumed.

In 1913 Germany had for sale to foreigners \$3 worth of these products as against every dollar's worth that it needed at home.

Nine hundred different dyes were on the United States markets of which one hundred were made or assembled in this country from intermediates purchased from Germany. Yet these one hundred do not seem to be enough for American dye users. How much less than the full nine hundred will satisfy American users is known to them and to the importers, the latter can not be expected to divulge that information, if the former want substantial help from American chemical makers they must divulge it no other way of ascertaining being available.

In 1909 the United States produced \$1462436 worth of artificial dyes which are probably artificial dyes in the strict sense. Compared with Switzerland's \$3,000,000 production the 'assembly' in 1909 this is an achievement of which Americans need not be ashamed. The wonder is not that we have not done more but that in the face of the well organized manufacturing plants of Germany and of Germany's very much superior facilities for foreign trade both banking and carrying, that we have done as much as we have. Blame should not be parcelled out for what American chemists have not done, but credit, which has been so far withheld should be given for what has been done in spite of obstacles abroad and obstacles at home. The users of dyestuffs have invariably opposed any tariff enactment that would substantially encourage a domestic production of coal tar dyes. That so many are produced in this country as are being produced is due to no cooperation of dye stuffs users but was accomplished in spite of their obstruction and if to day the users are in serious difficulty through a lack of dye stuffs they have their own shortsightedness to blame and can not, by any argumentation whatever, shift the blame to American chemists. With proper help and encouragement the American chemist will be able to increase the domestic production of coal tar dyes

and to inaugurate the making of intermediates, in the course of time this country may then ultimately look forward to a substantial share of the world's coal tar dye business.

Hardly any of the valuable or useful intermediates ever were patented. A considerable number of non-German chemists have invented and patented finished dyes made from non-patented intermediates. These inventors had perfect freedom to make the needful intermediates and an exclusive right to make sell and use their new dyes therefrom, yet they bought their intermediates from Germany rather than make them themselves. The patent situation is therefore really that Germany excelled the rest of the world in making patentable combinations from non-patented and non-patentable intermediates and further in making those non-patented and non-patentable intermediates in open competition with the rest of the world. So, from one point of view it appears that the rest of the world, inclusive of the United States lay back let the Germans do all the hard work and when the rest of the world finally woke up to the value of what the Germans had accomplished they became very busy making excuses and explaining instead of making a determined direct, united and effective attempt to recover the ground so lost. That such a recovery will require the hardest kind of work on the part of all users, capitalists, consumers and makers alike is self evident and obvious and the question is: do we want to pay the price? It can be done, if the price be paid.

At the conclusion of Dr. Hesse's lecture the directors were called upon for remarks. One well qualified arose and simply quoted from Mrs. Stowe's "Old Town Folks":

One of the characters Sam Lawson had gone to 'meetin' house' to hear the new preacher and returning shortly afterwards to the kitchen where the "women folks" were preparing the meal they inquired of him why he happened to come so soon — "surely meetin' couldn't be out."

He replied "No meetin' isn't out, but the preacher said how by a state of natur' we were all down in a deep well, and the sides of the well were glar ice. There warn't one in ten warn't one in one hundred, warn't one in a thousan' never get out, and yet it war the particlur duty of every one of us to get out. At that pint in the discourse I rose and went out thinkin' any one was welcome to my chance."

From the foregoing it will appear as if the opportunity to produce colors and other articles and products in a large way in this country while open are not likely to be availed of to any great extent during the existence of the present war unless the war should last much longer than even the most pessimistic fear.

I might say however in this connection that I remember distinctly being told by one of the best authorities on the subject that it was absolutely impossible to manufacture Portland cement in this country and it might just as well be put aside as one of the things for which this country was not adapted. I have also heard exactly the same statement regarding soda ash and caustic soda and yet these articles some how or other have become rather important articles of our manufacture and for a long time we have not been obliged to call loudly for outside help.

In spite of the difficulties however some feeble steps have been taken here partly I confess out of curiosity to learn if it were really true that our country lacked the self respect to hold all the treasures it should possess when strange to relate out came aniline oil of the best quality. What happened then is worthy of note as it shows at least one state of affairs which it is necessary to correct if we are going to escape from the dilemma which discouraged Sam Lawson. As soon as American aniline oil was offered for sale down went the price below cost. A tariff of 10 per cent put upon it by Congress as a compromise between judgment and party was immediately absorbed by the foreign makers and the price here became lower still. You see on the other side of the Atlantic they believe in cooperation. Here our legislators think we believe in destructive competition and have made cooperation one of the seven deadly sins. Nothing but

demonstration by the ballot box will prove the contrary. A man with his ear to the ground does not always hear the "music of the spheres." The low price of aniline oil had no relation to its cost. It was simply dumped by agreement to discourage the American infant. And it did.

Many devices have been suggested to encourage the coal tar dye industry in this country such as a high protective tariff and changes in the patent law.

The former does not seem likely to be evolved although a good deal can be said on the side that a high tariff in these articles would either result in the establishment of the industry or else produce a considerable revenue either end most desirable to attain. The latter is such a complex subject that it is not so clear that good results would ensue on changing the patent laws. While it is important to establish a coal tar dye industry as far as is practicable we must not be selfish enough to forget that there are other important industries already established and the American people must learn more and more to consider the rights and needs of the individual in their relation to the rights and needs of all.

Another obstacle besides the patent laws and the absence of tariff protection to the establishment in this country of any new industry strongly entrenched abroad, is to be found in the inadequacy of the anti-trust laws to protect American industry against systematic dumping of goods from abroad at prices substantially less than foreign prices with intent to injure or destroy the local industry.

Much has been done by the present Congress in the creation of a trade commission and in the statutory condemnation of certain specific practices to render those laws more efficient, but, taken as a whole, the efficiency of those laws, so complete for

domestic commerce, is quite unsatisfactory when applied to imports from abroad, and that despite the very real help to be expected from the new trade commission

The trouble lies partly in the inherent difficulty of the subject and partly in the inadequacy or ambiguity of previous legislation. First of all, our anti-trust laws can have no extra-territorial force. Cartels and trusts that would be invalid here are lawful abroad, and in so far as these operate on their own soil, even to our detriment the individuals concerned can with difficulty be reached so long as the acts done are lawful in the country where they are done. But these unfair practices must express themselves in imports into this country, and this implies the existence of importers or agents who must either be, or occasionally come, within the jurisdiction of our laws.

And so we find in 1894 our Congress partially legislated on this very subject, and by the anti-trust sections of the Wilson tariff law (secs 73-77) visited upon importers who should combine in importing to restrain trade in this country all the pains and penalties of the Sherman law of 1890, namely, fines, imprisonment, forfeiture of goods in transit, triple damages, injunction and dissolution.

But this Wilson bill which may well be deemed to be the exclusive expression of congressional purpose on this subject of imports, is confined to restraint of trade by two or more—and it does not, like the Sherman law, prohibit monopolizing, nor acts done by one person or corporation alone, nor does it prohibit unfair methods as such.

Now the unfair methods here complained of are precisely those which tend to monopoly by the destruction of competitors, and they can as well be employed by a single powerful concern as by a combination.

Viewed merely as "unfair methods," it is probable that they would not have been held by the courts to have fallen under the Sherman law so long ago as 1894, but would have been classed among those acts which the Supreme Court has lately characterized as "no more than ordinary acts of competition or the small dishonesties of trade."

But in the last few years ideas on this subject have undergone a complete change, and many methods formerly thought legitimate have passed under the ban of the law. Railway rebates are a notable example of this, and now with the legislation of this year we find legislative authority for the condemnation of unfair methods of competition generally, and notably discrimination in prices with intent to injure.

Admirable as are these provisions, there is nothing in the new statutes which extends their scope by way of amendment to the Wilson bill and to imports—and there is much to indicate the legislative intent to confine those provisions to domestic commerce alone. The word "commerce" both in the unfair methods clause (sec 5, commission bill) and in the price discrimination clause (sec 2, Clayton bill) is defined as commerce among the states or between this country and a foreign country, and this definition excludes the idea of its including also commerce within a foreign country.

The practices that we complain of involve commerce not in the restricted sense as defined but a commerce that includes foreign countries as well as our own. But if these practices of foreigners and importers are nevertheless to be deemed unfair methods within the commission bill (sec 5), the only remedy for them is an order of the trade commission to desist. They are not expressly prohibited by the act itself, nor made punishable in any way. If, however,

these practises are to be deemed price discriminations within the Clayton bill (sec 2), which seems impossible, then the only remedy besides an order to desist is a right to sue for triple damages. The difficulty in estimating any damages at all is obvious enough in any case, especially so in the case of the destruction of a small *new* industry, and still more so in the case of an embryo industry that has never raised its head.

Even if Sec 2 of the Clayton bill apply, we must assume that it creates a new offence not included in either the Sherman or the Wilson bills, hence that there would be no authority of law for any remedy except those alluded to as given in the act creating the offence, especially so inasmuch as the Wilson law stands out unrepealed as the sole legislative expression on the subject of imports and is silent and unamended upon the subject of price discrimination.

If this conclusion be correct (and it is almost as bad if the law be in doubt) there exists a situation where the equal protection of the laws is not extended to the importer and the domestic manufacturer alike. On the contrary, a practical license is given to the importer to do that which the citizen is forbidden to do.

The foreign manufacturer or importer seldom has any inducement to act in restraint of trade as we commonly understand it, or to monopolize competing plants in this country, quite the reverse. His object is to build his monopoly by destroying a domestic industry, and one of his most potent weapons in doing this if he be well enough entrenched is to drop prices in this country below the prices which yield him profits abroad for a long enough period to drive out American competitors, when, having the market to himself, he may raise them again.

The penalties to be invoked against the foreign manufacturer and importer as deterrents are utterly inadequate to deter them from trying it on as before. The most that they can suffer from their practises is, as we have seen, a commission's order to desist, and perhaps in some cases a suit, difficult to prove for triple damages.

What is needed is that these people should have before their eyes the same deterrents of fine, imprisonment, forfeiture of goods, triple damages, possible injunction and dissolution as have rendered American business men careful neither to restrain trade nor monopolize nor indulge in unfair practises. The practises here condemned in reality amount to much more than mere unfair methods of competition, they verge on an illegal attempt at monopolizing. It is of the essence of monopolizing to exclude. The legislation of 1914 does not subject unfair methods in general to the criminal features of the anti-trust laws, and this is doubtless wise. But this particular offence is in its nature monopolistic and criminal and it is the most effective form by which the foreigner can evade our anti-trust laws and illegally injure or destroy American industry. What is needed is an amendment of the anti-trust sections of the Wilson tariff act carrying into it the prohibitions against monopolizing of the Sherman act even when practised by one person alone, and expressly defining the practise here condemned as an act of monopolizing. The pains and penalties of the Sherman and Wilson acts would then follow on these practises as a matter of course.

At the present time, when there can be no longer any thought of procuring additional protection of new industries through the tariff, it will be rash to hope that American capital and enterprise should further

embark in any of those industries new or unknown here which are firmly intrenched abroad and where as soon as the war is over the foreigner can return to the work of attack and destruction by the methods above mentioned

This plan which aims to place Americans and foreigners on the same footing here could it seems to me be easily and quickly enacted by the present Congress. It would put American manufacturers including American chemists in a position to act without having all the chances against them. Are they not entitled to at least this much?

I do not believe in hothouse development of industries for which we are not adapted but save us from the cold storage conditions resulting from perfect organization being arrayed against us so that our real opportunities which we are in every way qualified to enjoy are frozen to death. The little aniline oil experiment alluded to above has come to life again and in its small way has proved during these war times to be a godsend to our manufacturers. It is gratifying to note that it is even growing in a manner which it is hoped will be permanent. It seems too bad that it should require a dreadful war to make such a little start possible. It should have been accomplished as soon as our by-product coke ovens and fuming sulphuric acid production made it possible.

To sum up the effects of the war on the chemical industry already established in this country are measured in general by their effects on the industries consuming chemical products. It has however been brought very close to us that certain industries not thoroughly established here but highly organized abroad are of tremendous importance to us. We have seen that this branch of chemical industry has been the

result of marvelous ingenuity, patience, research and cooperation during the more than half century since Perkin produced the first coal tar dye in England. One of the lessons to us which it seems to me lies near the surface and probably one of the most important lessons this people must thoroughly learn is that of cooperation which has had more to do with the making of the great coal tar chemical industry than any other one influence. We as a nation have passed our childhood and youth; we have made gigantic progress at tremendous cost of materials and possibly of moral fiber; we have come to the parting of the ways. If we continue too long as we have been going we will deserve disaster if we do not actually experience it. We know on the highest authority that a house divided against itself must fall. The laws of the resultant of forces familiar to us all show us what would happen if we all pulled in different directions. I feel strongly that our future success as a nation lies in universal cooperation—the government and its departments with the manufacturer, the manufacturer with the workman and all together for the country and for the world; and this cooperation must not be based solely on self interest but more particularly on those moral qualities which lie at the foundation of universal brotherhood. It must not be the survival of the fittest but the survival of all and the very best that is in them brought out of all. When we have learned and adopted this lesson of cooperation for the good of all we have started on the road to a national greatness both material and moral which I modestly feel that the possessions of this people qualify it richly to enjoy.

WM. H. NICHOLS

NEW YORK, N. Y.

THE RELIEF OF OUR PACIFIC COAST¹

EVER since the landing of the Pilgrims on Plymouth Rock and the founding of Jamestown, if not even in the Garden of Eden, "Westward Ho" has been the cry, and the inspiration of this call of the wild is well portrayed by Leutze in his famous painting at the national capitol

"Westward the Star of Empire takes its way" is no less true to day than two centuries ago, but from a more commercial point of view

The near sea level transcontinental water route of the Panama Canal is in strong contrast with the bold relief of the immigrant route of the early days in wagons across the Great Plains and Rocky mountains with the privations of the Great Basin to the ranges of the Pacific coast with luxuriant wealth of forest and field, affording the framework for the Golden Gate where the Panama Pacific Exposition is about to celebrate the opening of the great canal

Many a traveler will find his way from the Atlantic coast to California on that occasion, and to prepare him for the strong contrast between the surface features of the two ocean borders I have selected as my theme on this occasion "The Relief of Our Pacific Coast" It will indeed be a great relief to the generous heart of the Pacific coast to welcome a large number of visitors to the Panama Pacific Exposition, but that is not the relief to which I refer It is to the form of the land surface, its ups and downs with reference to the sea level along our Pacific coast, that your attention is invited It is the subject which in one form or another has held

my attention as a field of investigation in connection with the United States Geological Survey for many years Do not be dismayed at this length of service as affording a suggestion of the duration of this discourse But quite the contrary, the proportion should be inverse for it seems quite probable that my eminent predecessor Professor Lesley was right when he declared that geologists talk too much, and I shall heed his admonition

The backbone of the North American continent is in the Rocky Mountain system relatively near the Pacific coast The great valley of the Mississippi lies to the east with the Appalachians and the coastal plain of the Atlantic States beyond A 200 mile wide belt on the Atlantic coast, at least from Virginia southward is a coastal plain and piedmont region without mountains or even big hills but on the Pacific coast the 200 mile belt is mountainous in the extreme from Canada to Mexico

The mountain belt of the Pacific coast is but a member of that merged group of mountain systems the Cordilleran, that runs through the western United States and Mexico and forms the continental bond of Panama now so happily pierced for the commerce of the world and so fittingly and attractively celebrated in the Panama Pacific Exposition

Indeed it is believed that the mountain belt of our Pacific coast is no small part of the attraction to the exposition It constitutes not only the framework of the Golden Gate, the scene of the great event, but in itself embraces some of the finest scenic features of the world among which are four national parks, the Yosemite, General Grant, Crater lake, and Mount Rainier besides three national monuments, the Pinnacles and Cinder Cone in California, the caves of Oregon, and Mount Olympus in Washington, all districts of

¹ Address of the Vice president and Chairman of Section of Geology and Geography American Association for the Advancement of Science, Philadelphia meeting, December 1914 Published with the permission of the Director of the U S Geological Survey

profound geologic and geographic interest and each so distinctive as to be especially attractive

The relief of a country may be expressed in terms of water power and considering the rainfall the water power is proportional to the relief. From this point of view the Pacific coast relief is greatly in excess of an equal area of the Atlantic coast.

The area of the direct drainage into the ocean from the Atlantic States is approximately 284 000 square miles² while that into the Pacific not counting the Colorado River is about one fourth greater than that of our Atlantic coast and yet the energy represented by the Pacific drainage is more than seven times that of the Atlantic coast. By far the greater portion is undeveloped and gives some idea of the latent possibilities of the empire of our west. Attention should be called to the fact however that much of the Pacific coast power is in the Columbia river of which the greater part lies east of the mountain belt but even excluding that portion of the Columbia the enormous power of the mountain belt greatly exceeds that of an equal area along our Atlantic coast.

With this may be coupled also that of the production of precious metals which are vein deposits formed as an adjunct of stresses that express themselves in relief. The production of precious metals in the mountain belt of the Pacific coast in recent years has been hundreds of times that of the Atlantic States.

The mountain building period on the Pacific coast bordering the larger ocean may have been longer and more intense than that on the Atlantic resulting in greater and perhaps later segregation so that erosion has not removed the moun-

tains as has been the case upon the Atlantic side.

That this is not simply a matter of time but of actual deformation and uplift may be inferred from the enormous deposits of limestone and coal to the east which indicate not only a region of low relief but low relief of wide extent. Strengthening the contrast in the relief of the coasts but balances the values of the mineral deposits.

PACIFIC COAST MOUNTAIN BELT

The continental feature bordering the Pacific coast of the United States is a mountainous belt of surpassing grandeur lying between the Great Basin platform of the interior on the east and the Pacific ocean on the west. It is the crushed and upheaved edge of the continent along the line of counter stress between the land and sea. The great uplifts of the earth's surface in that region are so young as to preserve much of the prominent form and mass resulting from the deformation.

It is remarkable for its lineal continuity with a width ranging from 100 to 200 miles throughout a length of 2 500 miles. Some of it indeed at both the northern and southern ends is below sea level but other portions especially in California, Oregon and Washington bear the highest peaks in the United States south of Alaska.

The general form of the belt is slightly sigmoid with a broad coastal curve to the west in northern California and to the east at the international boundary (49th par.) resulting from large structural features which will appear in an analysis of the members of the belt.

The general features of the belt are two lines or ranges of mountain elevations with a great valley between. For the most part the two lines of mountains appear to be parallel with each other and the coast; the Sierra Nevada and the Cascade ranges on

² Water Resources Paper No. 234, pp. 52-57.

the east and the coast ranges, including the Klamath mountains of California and Oregon and the Olympic mountains of Washington on the west from near the Mexican line to British Columbia. They are separated by a depression, a great valley more or less continuous from the Gulf of California and Salton Sea on the south through the Great Valley of California, the Willamette Valley of Oregon and Puget Sound to Georgian strait on the north, which it enters and follows with less definition along the coast of British Columbia to Alaska, a total distance of about 2,500 miles.

In the United States there are only three rivers, the Columbia, the Klamath and the Sacramento (including the Pit), which cut across the entire mountain belt from the interior platform to the sea, although three others, the Chehalis, Umpqua and Rogue rivers, rise on the west slope of the Cascade range and break through the coast range.

The mountain ranges which now constitute the topographic limits of the Great Valley of the Pacific coast are composed of parts that differ widely in origin, age and composition.

THE SIERRA NEVADA

The Sierra Nevada is a massive mountain block, 350 miles long and 80 miles wide, with a long gentle slope west to the Great Valley, and to the east has a short steep slope, due to faulting, that separates the rocks of the Sierra from those of the Great Basin.

The Sierra Nevada is composed of sedimentary and igneous rocks of various ages, from Silurian to Jurassic, which have been closely folded and intruded by batholithic masses of granitic rocks. The folding and intrusion have greatly altered the rocks and developed in them numerous metaliferous veins, chiefly of auriferous quartz.

During a long period of erosion which washed away the mountains and reduced the country to low relief the veins gave rise to auriferous gravels, and some of the earlier of these gravels in the northern portion of the range are covered by flows of Tertiary lavas.

The southern and central portion of the range where granodiorite prevails is one great topographic block bounded on the east by a fault zone, which curving to the west around the southern end, meets the San Andreas fault of recent earthquake fame and brings the Sierra Nevada and the Coast range together. In the northern portion of the range along the eastern side of the great block, adjoining the Great Basin and suggesting its structure, there are two smaller fault blocks, one of which locally has sunk for Lake Tahoe, while the other forms the bold eastern escarpment of the range.

The Tertiary lavas of the Sierra Nevada are continuous to the northward with the great pile of volcanics in the Cascade range, beneath which the older terranes of the Sierra Nevada disappear with a strike of approximately N. 50° W. toward the Klamath mountains, about 60 miles away. Some minor faults appear in the lavas of the Lassen Peak region but major faults like those which characterize the Sierra Nevada have not yet been recognized in the Cascade range.

The faulting which limits the Sierra Nevada on the east, as emphasized recently by Ransome, has been of long duration and is still in progress, as evidenced by the many small earthquakes at points along its course. The Owens Valley earthquake of 1872 is the most notable example resulting from a fault of 10 feet.

The earthquake was widely felt, but there are many that are not felt at all under

ordinary circumstances, and yet may be clearly detected and their intensity and duration measured by a seismograph. Every earthquake indicates a change in the relative position of the rocks, however small, either horizontal or vertical or both, and consequently in the relief of the country. It may truly be said that the mountains are growing. In no other part of the United States is there as great seismic activity as along our Pacific coast, a fact which means that the mountains are not only growing, but growing faster than elsewhere in the United States. Some are growing less, others greater, and there is need, as pointed out by Lawson, of establishing bench marks on opposite sides along the faults, so that the amount and character of the change may be measured.

The transformation of the Sierra Nevada from a region of low relief to one of high relief so increased the river grades of its western slope that they have carved out deep canyons which now form the principal relief feature in the scenic attractions of the range. The Yosemite Valley is the finest example, although rivaled by that of Kern River, and is one of our most impressive and instructive national parks. This is especially the case since nature has made some of the finest trees in the region big in proportion, as if to correspond to the size of the canyon.

KLAMATH MOUNTAINS

The Klamath Mountains are an irregular half crescentic group of peaks and ridges along the coast in northwest California and southwest Oregon. The general shape is that of a saddler's knife, with the curved side to the west and the handle to the east, a little south of the center. Their greatest extent north and south is about 225 miles, with 75 to 115 miles in width. The crescentic border follows the coast for

about 90 miles north from the mouth of Klamath River in California to near Rogue River in Oregon. To the northwest of the Klamath Mountains is the coast range of Oregon. To the southwest is the coast range of California, both overlapping the western curve of the Klamath Mountains along the coast. On the east lies the Rogue River Valley, Shasta Valley and Sacramento Valley bordered by the great lava field of the Cascade range.

The Klamath Mountains are composed chiefly of Carboniferous and Devonian sediments, with a large proportion of contemporaneous lava flows of rather basic types. Besides these there are large bodies of mica and hornblende schists of pre-Paleozoic age, as well as sediments and effusives belonging to the Jurassic and Triassic.

These rocks are folded, faulted and intruded by batholithic masses composed of granodiorite, gabbro and peridotitic rocks centering in a general core with aligned terminals that curve to the northeast in Oregon and southeast in California. The later sedimentary rocks of the Klamath Mountains, the Jurassic and Triassic, are richly fossiliferous in the Redding quadrangle, where they are associated with equally fossiliferous Carboniferous and Devonian strata that form the hills lying east of the Sacramento River and the railroad between Redding and Mt. Shasta. In the southern part of this exposure the Mesozoic rocks strike S. 50° E. in line with rocks of essentially the same age and position 75 miles away in the northern portion of the Sierra Nevada. To the northward in the Redding quadrangle we see these Mesozoic rocks curve to the right and strike to the northeast in the general direction of the Blue Mountains of Oregon. Now this change in the strike is not limited to the eastern portion of the Klamath Mountains

in the Redding quadrangle but more or less distinctly marked it extends throughout the great stretch of the Paleozoic rocks of the whole group in both California and Oregon. Furthermore the same curved trend is suggested by the form of the intruded masses. The mass of granodiorite between Lewiston and Igo extends south east and widens directly toward the Sierra Nevada where similar rocks are abundant.

While the composition and the plication of the rocks of the Klamath Mountains tend to show close relationship to the Sierra Nevada it is only partial and in reality the two are distinct, being separated in the first place by a wide depression probably due as long ago pointed out by Whitney, to a fault across the trend of the range and in the second place characterized by a series of overthrust faults quite unlike those which obtain in the Sierra Nevada.

Although the detailed structure of the Klamath Mountains has not been worked out, some of the major structures have been apprehended by Hershey and others sufficiently for consideration in this comparison of the several ranges of the Pacific coast chain.

The southwest limit of the Klamath Mountains against the coast range of California is marked by a profound thrust fault on which the highly crystalline schists of South Fork Mountain appear to have been thrust to the southwest up over the Cretaceous and Jurassic rocks toward the coast. The fault runs northwest and south east and the hard schists give rise to a prominent long even crested mountain ridge, one of the most conspicuous members of the Klamath Mountain group.

In Oregon a similar fault occurs through the Kerby region of Josephine County where Devonian rocks are in effect thrust northwest toward the ocean up over those of Jurassic age. The fault runs northeast

and southwest and erosion has developed prominent mountains facing the valley that lies to the northwest.

The Kerby fault if continued southwest in the same strike would intersect the South Fork Mountain fault but according to Hershey before it reaches the South Fork Mountain fault it curves to the south and finally southeast so as to parallel the South Fork Mountain fault.

Farther east there is another fault belt which at the south end in California trends southeast while at the northern end in Oregon its course is to the northeast. Like the other it appears to be a thrust fault. Hershey has estimated the overthrust locally in one of the Klamath Mountain faults as much as a mile.

The curved thrust faults traversing the Klamath Mountains are in strong contrast with the normal faults of the Sierra Nevada. The Klamath Mountain thrust is to the westward. The downthrow of the normal faults in the Sierra Nevada is to the eastward. Thrust faulting occurs also locally in the Sierra Nevada but at Taylorsville the thrust is to the eastward.

The Klamath Mountains are insular in character. Composed largely of Paleozoic rocks and surrounded by rocks of later age, they formed a buttress in the development of the coast ranges of California and Oregon. From the Sierra Nevada they are separated by a depression in the older rocks that extends northward beneath the Cascade range.

During a portion of the Cretaceous the Klamath Mountains were above sea level, but the gradual subsidence of the land almost or quite completely immersed them at the close of the Chico epoch, as shown by the rather widespread occurrence of fossiliferous fragments of sandstone from the Chico formation in the auriferous gravels of that region. During the early Ter-

tiary the region was a lowland of gentle relief cut down like the Sierra Nevada to a peneplain but later it was raised as perhaps the great valley sank and became a prominent mountain group

THE COAST RANGE OF CALIFORNIA

The coast range of California lacks the wealth of precious metals found in the Sierra Nevada and for that reason until recently it has not received so much attention from geologists. But the discovery of oil and its development has greatly stimulated research in that field. Only a few districts have been surveyed in detail and published but much general reconnaissance has been done. What we know of the composition structure and history of the range has been admirably summarized by A. C. Lawson and Ralph Arnold. Their summaries have recently been discussed in a most helpful critical way by Ransome who is himself familiar with portions of the region.

The coast range of California according to Lawson extends from the Mexican boundary to near the mouth of Klamath River with a length of about 720 miles a width ranging from 40 to 60 miles and a general trend of N 30° W.

At the northern end Lawson includes the South Fork Mountain in the coast range but it seems to me that the great fault on the western slope of South Fork Mountain is the delimiting feature and keeps the South Fork Mountain and Yallo Bally in the Klamath group.

The coast range is regarded by some and Ransome among them as ending on the south at the headwaters of Santa Maria River where the Tehachapi range joins the southern terminus of the coast range to the Sierra Nevada.

South of the Santa Maria River is a group of ridges including the San Rafael

Santa Barbara Santa Ynez San Gabriel, San Bernardino and other ranges which although not strictly parallel have a general trend nearly east and west. These ranges embrace the Los Angeles country and have been most appropriately referred to by Ransome as the Sierra de Los Angeles.

The coast range throughout is composed of a succession of parallel ridges which south from San Francisco to Santa Maria River trend about N 43° W while in the northern portion of the range the trend is N 26° W giving an average course of N 30° W for this portion of the range. Everywhere the course of the ridges is more or less oblique to the coast line which is made up of a series of zigzags that Lawson regards as probably due to faulting parallel and transverse to the ridges thus cutting them off on the shore and affording excellent exposures of the composition and structure of the range.

The coast range of California is composed chiefly of Mesozoic and Tertiary rocks with some that are older as well as a considerable portion that belong to the Pleistocene. The oldest rocks are marble quartzite mica and hornblende schists like those of the Klamath Mountains and Sierra Nevada. They appear mainly as inclusions in the granitic rocks which form the concealed basement of the coast range and upon which was deposited unconformably the Franciscan formation a complex succession composed in the main of strongly indurated sandstone with subordinate quantities of shale and conglomerate a considerable part of radiolarian chert and foraminiferal limestone. In the upper part of the formation are interbedded lavas and the whole is intruded by peridotite and basalt. A thick series (29 000 feet) of shales sandstones and conglomerate of Cretaceous age follow unconformably on the crushed Franciscan and are succeeded by an extensive

succession of shales, sandstones and conglomerates of Tertiary and Quaternary age.

In composition the coast range is in strong contrast with the Sierra Nevada, being much the younger. There are great differences in structure also. The rocks of the coast range are folded, as Lawson points out, in rather sharp synclines and anticlines, some of which are overturned, as in the Monte Diablo region, toward the ocean and thrust faulted, but they are never so closely appressed as to indicate general and important deformation of the internal structure of the rocks affected. There has been no development of slaty cleavage or schistosity. In general, the axes of the folds are northwest-southeast, and although the minor folds may be more or less divergent, the major folds are parallel and extend for many miles. The coincidence of many of the larger valleys with a synclinal axis is very marked.

The coast range throughout is a faulted range and the faulting has had even more to do with the form of the relief than the folding. Many of the valleys are fault valleys with unsymmetrical slopes, the fault lying near the steeper slope. The faults, too, are especially interesting because of the earthquakes they produce. Faulting is still in progress, and each slip or movement along the fault plane results in a shock. The great earthquake of 1906 resulted from a slip along the San Andreas rift which has been traced for 600 miles. The movement was greatest in the neighborhood of San Francisco and chiefly horizontal instead of vertical, as is perhaps generally the case. Hundreds of faults slip and slight shocks occur in California every year, and perhaps hundreds more too gentle to attract attention.

The coast range as a whole may well be outlined by faulting. The steep bluff of the coast beneath the shallow and the deep

sea is probably due to faulting, and the eastern side of the range in Tehama and Shasta Counties has a series of large sandstone dikes that evidently resulted from an earthquake, possibly in Tertiary time. Unlike the Sierra Nevada, which is mainly one great block tilted so that the streams consequent upon the tilting flow directly transverse to the range, the coast range is composed of many blocks with the main divide along the eastern edge, but the streams, instead of being wholly consequent, taking the shortest route directly to the ocean, are subsequent and follow the lines of easiest erosion along faults and folds to the sea.

According to Ransome, referring to the work of many others, the structure of the Sierra de Los Angeles appears to show a transition from a combination of folding and faulting such as is characteristic of the coast ranges to tilted block mountains, exemplified by the San Bernardino range, such as are characteristic of the Great Basin.

Much yet remains to be done before a comprehensive statement can be formulated concerning the structure of the coast ranges as a whole, but with the large corps of workers from the universities at Berkeley and Stanford and the United States Geological Survey as well as others in the field the detailed information is rapidly accumulating.

The coast route from Los Angeles to San Francisco is in the coast range throughout the entire trip and affords an excellent opportunity to observe many of its features.

THE COAST RANGE OF OREGON

If in California we have in the Pacific system two ranges, the Sierra Nevada and the coast range, which are strongly contrasted in composition, structure and age, in Oregon we have two ranges of still

greater contrast, not only in composition, structure and age, but in mode of development.

The coast range of Oregon extends from Cape Blanco in Oregon through Washington to the strait of Juan de Fuca, a distance of nearly 400 miles. At the southern end it abuts against or rather runs into the Klamath mountains without any sharp topographic termination. At the north it ends in the Olympic mountains of bold relief, reaching an altitude of 8,150 feet, but not quite reaching the height of the Klamath Mountains. South of the Columbia along its crest are Onion Peak, Saddle Mountain and Mary's Butte, of which several are volcanic.

On the whole the range is a unit but irregular and, as compared with the Sierra Nevada and coast range of California, is characterized by its lack of effect upon drainage. Although of small extent, it is cut across by four rivers, the Umpqua, Nehalem, Columbia and Chehalis.

It is composed wholly of Mesozoic and Tertiary rocks which at both ends abut against those of the Paleozoic age. The Franciscan series of sandstones, shales and cherts of Franciscan age, with serpentine and other intrusives, form a large part of the Olympics and a portion of the southern terminus of the range in Oregon, but have not been recognized in intermediate portions of the range. The same is true of the Cretaceous, especially the Upper Cretaceous, which lies with marked unconformity upon the rocks of Franciscan age and thus records the great diastrophic epoch of compression, probably about the close of the Jurassic.

The Cretaceous on the Pacific coast was a time of subsidence so profound, at least in one locality, as to result in the accumulation of 29,000 feet of deposits in a moderately shallow sea which transgressed the

sinking land until it reached the base of the Sierra Nevada. In Oregon there was apparently a great embayment covering not only the northern end of the Klamath Mountains, but extending inland beyond the Cascade range to the base of the Blue Mountains. This great sinking embayment, as it were in the lee of the Klamath Mountains, the stable and insular terminus of the Sierra Nevada, is an important feature of both the Cascade and the coast ranges in Oregon. The steeper inclination of the Cretaceous strata as compared with the Eocene indicates their unconformity, and the discordance is the greater in proportion as the underlying Cretaceous is older.

The Eocene sandstones and shales, although mainly marine, are in part of fresh or brackish water accumulation and contain locally more or less important deposits of coal. They form the bulk of the coast range in Oregon and southwest Washington, and with them are associated in many places contemporaneous volcanics, for the most part basalts.

A large part of the coast range in Oregon and Washington south of the Olympics was probably not raised above the ocean before the close of the Eocene, but at that time the elevation became somewhat more pronounced, forming a low ridge which with minor oscillations admitted the Miocene sea through the gateway of the Chehalis and Columbia into the Willamette Valley.

Toward the southern end, where the Eocene contains some marine sandstones derived from the near shore of the Klamath Mountains, the coast range is gently synclinal. It presents a bold bluff with even crest to the Umpqua Valley, possibly due to a fault. Although, as a whole, the coast range of Oregon has not been subjected to as great compression as that of

California, nor cut into parallel ridges by large faults, yet in places along the coast, as at Coos Bay, the thinner bedded Eocene has been folded and compressed into a vertical position. The later intermittent uplift during the Quaternary is recorded by a series of elevated beaches cut more or less deeply on the west slope by the ocean waves.

THE CASCADE RANGE

The Cascade range is essentially a volcanic range stretching from Lassen Peak in California to Mt Rainier in Washington, a distance of 450 miles. At both ends the lavas lap up on to the uplifted mountains of older rocks, the Sierra Nevada in California and the northern Cascades in Washington, but between these two from the Columbia River in Washington to the Pit River in California, for a distance of nearly 300 miles, the range is composed largely, if not wholly, of igneous rocks that have escaped from a great belt of volcanoes that form the range. The summit of the range is an irregular plateau strewn with many lava and cinder cones, of which each one marks the site of a volcanic orifice tributary to the upbuilding of the range.

Where best developed, as shown in the Klamath and Columbia river sections, the body of lava forming the range is on the average probably about 4 000 feet in thickness, but in the greater volcanoes like Hood, Jefferson, Mazama, Shasta and Lassen it rises to accumulations of 6 to 10 000 feet in thickness. The later foundations of the Cascade range were laid in the Oregon embayment during the Cretaceous and early Tertiary times, possibly before the ranges were distinctly outlined. The Tertiary volcanic effusions began in Oregon west of the Cascade range during the Eocene and possibly a little later in the same epoch eruptions began in the base of the Cascade range. During the later Ter-

tiary the volcanic activity was greatest and the bulk of the range, though partly uplifted, was in equal or perhaps even greater measure upbuilt by flows of viscous andesitic lavas with much ejected material. Basalts are common and some acid lavas are known, but the great bulk of the range is andesite in strong contrast with the great lava plains east of the Cascades, where the thin basalt flows spread out horizontally like sheets of water. The change from the plain to the mountain slope at the eastern base of the Cascade range is abrupt and distinct, and due for the most part, to the fact that the stiff viscous andesitic lavas were able to build up steep slopes while the superheated and highly liquid basalts spread out like water along the irregular mountain front.

After the close of the Tertiary the volcanic activity waned, although eruptions occurred to within the historic period and possibly even to the present day if the outbursts from the summit of Lassen Peak develop so as to involve molten material.

However that may be, there is no doubt that the Cinder Cone and its lava field 10 miles northeast of Lassen Peak resulted from one or more eruptions within a century or two. In 1843 both Baker and St Helens were in violent eruption, ejecting large quantities of ashes, of which Fremont obtained samples collected at the time of the eruption. There is also well attested authority that eruptions occurred on Mt Baker in 1854 1858 and 1870. In general, however, the volcanoes of the Cascade range are considered extinct, and the upbuilding of the Cascade range completed as far as the actual accumulation of lava is concerned.

While the great altitude of the range is due chiefly to the piling up of lavas, a considerable portion is due to actual uplift, for in the Cretaceous of the Rogue River valley

marine shells now occur at the elevation of 3,000 feet which must have been elevated to that amount. The same may be said of the Eocene. It is, however, important to note that the uplifting of the Cretaceous and Eocene sediments about the close of the Tertiary was connected with the Klamath Mountains rather than that of the Cascade range.

Faulting that has played so large a rôle in the development of the Sierra Nevada and the coast range of California has not given general features to the volcanic mass of the Cascade range. Small faults are common in the lavas southeast of Lassen Peak, forming lines of bluffs and bringing the ground water to the surface in large springs, a feature which is common also in the Klamath Lake region and as pointed out by Russell, along other portions of the range, but these small faults have no effect on the general form of the range.

Along the western base of the range in the Willamette Valley, Washburne has pointed out some features suggesting a fault, but as yet its existence is a matter of doubt. There is no great relief feature in that region that appears to have originated in faulting. Farther south in the Rogue River valley there is a regular practically conformable succession from the Cretaceous through the Tertiary sediments to the overlying lavas of the Cascade range. Small faults occur in the Eocene coal beds which dip beneath the range but the faults are connected with the local intrusion of the lavas and not of large extent connected with the uplifting of the range.

While it is evident that the lavas of the Cascade range are faulted, I think Russell has greatly overestimated the effect of the faulting as a factor in the upbuilding of the range, which, as it seems to me, is a great pile chiefly of viscous andesitic lavas from many confluent cone capped vents, in

strong contrast to the coneless basalt plains in the formation of which the high degree of fluidity in the outflowing lava was the most important factor.

THE GREAT VALLEY

Of all the relief features of our Pacific coast mountain belt the least impressive and yet the most important is the Great Valley where live by far the larger number of people, with railroads for transportation, and produce from the alluvial soil washed in from the adjacent mountain ranges the main portion not only of their own subsistence, but much for other parts of the world. The great valley extends throughout the entire mountain system, but not without interruptions, and in fact these interruptions are so marked in certain localities, as between the heads of the Sacramento and Willamette rivers, where the valley is obscured by cross folds from the Klamath Mountains, that some geologists have doubted its continuity. When these cross folds and their effect upon the great valley are clearly understood it will be recognized that the valley is the great feature of the Pacific mountain belt with its history deeply buried in and beneath an enormous mass of sediments.

THE INTERNATIONAL COMMISSION ON BOUNDARY WATERS

Mr ADOLPH F MEYER, associate professor of hydraulics in the college of engineering of the University of Minnesota, has been engaged as consulting engineer for the International Joint High Commission, in connection with investigations made on boundary waters. These investigations have extended over the past two and a half years, and in this work Professor Meyer has been associated with Mr

Arthur V. White, of the Conservation Commission of Canada. This gives the United States one consulting engineer and Great Britain a second. The work has involved extensive investigation relating to the regulation of the levels of the Lake of the Woods, and the utilization of the waters tributary to that lake. Water power and water supply, navigation, fishing and agriculture are the chief interests concerned. Minnesota is vitally interested in this investigation inasmuch as about 11,000 square miles of the drainage basin of the Lake of the Woods lie in this state.

A dam controlling the level of the Lake of the Woods is located in Canadian territory. The shores of the lake on the Canadian side, particularly in the vicinity of the dam, are very high, but on the Minnesota side the slope of the land toward the lake is only a few feet per mile.

Settlers have been complaining to the United States government that the lake has been materially raised and that much of their land is being flooded. The first complaints were made more than twenty years ago. During the wet year of 1905 renewed protests were sent to the Department of State, but all efforts at securing settlement through diplomatic channels failed, until finally, soon after the appointment of the International Joint Commission in 1910, this question of the regulation of the levels of the Lake of the Woods was referred to this commission.

The International Joint Commission is a permanent tribunal with powers of adjudication, created by treaty between Great Britain and the United States. While the work of this commission thus far has concerned primarily the use of boundary waters along the Canadian frontier, the powers conferred by the treaty are very broad and include, in fact, the decision of practically all matters of dispute between citizens of the United States and Canada, referred to this body by their respective governments.

All obstructions or diversions of boundary waters affecting the natural level or flow of such waters on either side of the line must receive the approval of this commission.

One of the important questions decided by the commission during the past year was that of the application of the power companies at Sault Ste. Marie, for approval of the obstruction, diversion and use of the waters of the St. Marys' River for the development of power. Another important question now under investigation by the commission is that of the pollution of boundary waters.

THE AMERICAN AMBULANCE HOSPITAL IN PARIS

WESTERN RESERVE UNIVERSITY is the first to respond to a suggestion made by officers of the American Ambulance Hospital in France, that leading American medical schools send to France corps of men to take charge of one of the hospital's services of 150 beds. The medical board of the American Ambulance Hospital, through Dr. Joseph Blake, has requested Dr. Crile to be the leader in the proposed plan. The expedition will be financed by the trustees and friends of the university and the Lakeside Hospital and left for France on December 30.

The American Ambulance Hospital was established by the trustees of the American Hospital at Paris almost immediately after the outbreak of hostilities. Ambassador Myron T. Herrick was actively interested in the project and the building of the *Lycée Pasteur* at Neuilly was secured. The present capacity of the hospital is 450 beds, divided into services of 150 beds each. The suggestion made by the medical board is that several of the leading medical schools of the United States send out staffs to take charge in succession of one of the hospital services of 150 beds, with operating rooms and equipment, for periods of three months each. According to the proposed plan the corps from the several universities would follow one another without interruption of service. The officials of the Ambulance Hospital believe that the opportunity is unrivalled for humanitarian service and for clinical experience and medical research.

Dr. du Bouchet is the executive head of the hospital and represents the institution with

the French war office. He also has one of the three services, which he directs personally. Dr. Crile will have free latitude in his own service to carry it on in any way he may desire.

The personnel of the Western Reserve University expedition includes:

Dr. George W. Crile, professor of surgery in Western Reserve University and visiting surgeon of Lakeside Hospital.

Dr. Samuel L. Ledbetter, Dr. Edward F. Kieger and Dr. LeRoy B. Sherry, now of the resident staff of Lakeside Hospital, who will act as assistant surgeons and clinical assistants.

Dr. Lyman F. Huffman, of the resident staff of Lakeside Hospital, who will act as clinical pathologist.

Dr. Charles W. Stone, assistant professor of nervous diseases in Western Reserve University and visiting neurologist of Lakeside Hospital.

Miss Agatha Hodgins and Miss Mabel L. Littleton, anesthetists

Miss Iva B. Davidson and Miss Ruth J. Roberts, from the operating room staff of Lakeside Hospital.

Dr. Crile takes with him also, to assist in a special research, Miss Amy F. Rowland, B.S., Mt. Holyoke College, and William J. Crozier, Ph.D., fellow of the department of zoology of Harvard University.

CHARLES SEDGWICK MINOT

At the meeting of the council of the American Association for the Advancement of Science held in Philadelphia on December 29, a minute was adopted in memory of Dr. Minot. Dr. Eliot, who was in the chair, stated that he had been associated with Dr. Minot for more than thirty years in the work of the Harvard Medical School and added a fit tribute of appreciation. The minute, which was presented by Professor Cattell and adopted by a rising vote, is as follows:

The council of the American Association for the Advancement of Science places on record its sense of irreparable loss in the death of Charles Sedgwick Minot and its appreciation of the value of his services to science, to education and to human welfare. Endowed with the best New England blood and traditions, trained there and in the

schools of France and Germany, keen in intellect, wise in counsel, sure in action, sincere in friendship, he devoted his life to the advancement of science, the improvement of education, and the betterment of the agencies on which science and education depend. His contributions to embryology, anatomy and physiology gave him leadership in those sciences; his high ideals of education aided in advancing the standards of medicine in America and in placing the Harvard Medical School in its commanding position. Not only by his original researches, by his masterly books and by his fine addresses and lectures, but in countless other ways he helped his fellow workers in science—in the construction of microtomes; in the establishment of a standard embryological collection; in the improvement of bibliographical and library methods; in the unit system of laboratory construction, followed in the beautiful buildings of the Harvard Medical School; in the early development of the Marine Biological Laboratory at Woods Hole; in the Boston Society of Natural History, of which he was president for many years and until his death; in the Wistar Institute for Anatomy and Biology, in the administration of the Elizabeth Thompson Science Fund and the Baehr Fund of the National Academy of Sciences; in international relations, as when visiting professor to Germany and in the foreign publication of his books; in the editing of *SCIENCE* and of journals of anatomy, zoology and natural history; in the founding and the conduct of the American Society of Naturalists and the Association of the American Anatomists; in the establishment of the convocation week meetings of scientific societies; for us especially by his leading part in the work of the American Association for the Advancement of Science, of which he was secretary of section, general secretary, twice vice president, president, a constant member of the council, at the time of his death chairman of the committee on policy. In the American Association, as elsewhere, Charles Sedgwick Minot leaves a vacant place which can never be filled. We take up our work sadly in his absence; but we know that it will in all the years to come be more fruitful for the heritage of his service.

SCIENTIFIC NOTES AND NEWS

At the Philadelphia meeting of the American Association for the Advancement of Science Dr. W. W. Campbell, director of the Lick Observatory, was elected president for the

meetings to be held this year in San Francisco and Columbus

PRESIDENTS of several of the scientific societies meeting in Philadelphia last week were elected as follows The American Society of Naturalists Dr Frank R Illie professor of embryology in the University of Chicago Geological Society of America Dr E O Ulrich U S Geological Survey American Psychological Association Dr John B Watson professor of psychology in the Johns Hopkins University

THE American Mathematical Society meeting in New York on January 1 and 2 elected to the presidency Professor E W Brown of Yale University

DR JOHN DRURY was elected president of the American Association of University Professors which was organized in New York City on January 1 and 2

THE gold medal of the Geographical Society of Chicago has been awarded to Colonel George W Goethals It will be presented to him at a dinner to be given by the society on January 23

THE Austrian Academy of Sciences has given Professor Wagner v Jauregg \$1250 for his research on the etiology of goiter Professor Honigschmied of Prague \$800 for his studies of the atomic weight of the radium elements and Professor Netolitzky of Czernowitz \$375 to continue his study of the history of foodstuffs

MR E J CHILNEY one of the assistant secretaries of the British Board of Agriculture and Fisheries has been appointed to the office of chief agricultural adviser and Mr F L C Floud to be an assistant secretary

It is stated in *Nature* that Professor T A Jaggar director of the Hawaiian Volcano Observatory and a group of his assistants had a narrow escape of their lives during a recent ascent of Mauna Loa The volcano had become active discharging large quantities of lava The scientific party while making an ascent to study the eruption was caught in a snowstorm and nearly overwhelmed by snow slides almost in the path of the lava streams

THE well known paleontologist Professor Otto Jaekel of Greifswald University Germany and a member of the Landwehr was wounded in one of the battles of the Yser Canal and is now recuperating at his home

DR IFF M BARNBY formerly of Elkhart Ill but more recently of Miami Fla has been awarded damages of \$41500 from the casualty companies on account of the loss of sight from a chemical explosion which occurred while he was making experiments in his laboratory

PROFESSOR JOHN J FIATHER head of the department of mechanical engineering of the college of engineering of the University of Minnesota is spending a years leave of absence in Scotland He has recently moved from Girvas which is on the seashore to Edinburgh his address being 20 Greenhill Place

DR R R DINWIDDIE pathologist and bacteriologist of the Arkansas University and Station who has been connected with the institution since 1887 has resigned with the intention of retiring from active service

LYMAN CARRIER agronomist since 1907 in the Virginia College and Station has accepted a position with the office of forage crop investigations of the Department of Agriculture and has been succeeded by T B Hutcheson associate professor in plant breeding in the University of Minnesota

DR HARVEY CUSHING professor of surgery in Harvard University delivered an illustrated lecture on 'The Portraits of Vesalius' on the evening of December 29 at the Army Medical School Washington

PROFESSOR EDWARD L NICHOLS of Cornell University delivered an illustrated lecture on

'Artificial Daylight' at the forty seventh annual meeting of The Kansas Academy of Science which was held in Topeka on December 22

ON December 11 Professor H B Ward, of the University of Illinois lectured before the Washington University Chapter of the Society of the Sigma Xi on the "Homing of Fishes"

THE Geographic Society of Chicago holds a meeting on January 8, at which an illustrated lecture by Miss Dora Keen of Philadelphia will be given, entitled "Across Paraguay"

THE Washington Academy of Sciences held a joint meeting with the Botanical Society of Washington on January 5 to hear an illustrated lecture by Professor J C Bose on "The Response of Plants"

PROFESSOR C S SHERRINGTON, Fullerton professor of physiology at the Royal Institution will deliver a course of six lectures at the institution on muscle in the service of nerve during January and February

THE Hunterian oration of the Royal College of Surgeons of England will be delivered by the president Sir Watson Cheyne on February 15

MRS WALLACE, widow of Dr A R Wallace died at Broadstone, Dorset, on December 10 after a long illness

PROFESSOR JAMES HARVEY PETTIT, professor of soil fertility in the college of agriculture and chief of soil fertility in the experiment station of the University of Illinois died on December 30 at Pasadena, California where he was spending a leave of absence in the hope of benefiting his health. Dr Pettit received his bachelor's degree at Cornell in 1900 and his doctor's degree at Gottingen in 1909. Since 1901 he had been connected with the University of Illinois. He was a member of the American Chemical Association and American Association for the Advancement of Science.

MR W W ROCKHILL, known for his explorations in China and Tibet under the auspices of the Smithsonian Institution, and the author of several works on this and other Oriental subjects, has died at the age of sixty years.

DR C R CRYMBLE, of University College, London, a fellow of the Chemical Society, has been killed in the war.

DR A VAN GEUCHTEN, professor of anatomy and neuro pathology at Louvain University, has died at Cambridge.

M LÉON VAILLANT, doctor of medicine and of sciences, formerly professor at the Faculté des sciences de Montpellier and honorary professor of the Museum of Natural History at Paris, has died aged eighty years.

AMONG examinations announced by the New York State Civil Service Commission applications for which must be received by January 15 are the following: Physiological chemist, State Department of Health, Salary \$1800 to \$2500. Applicants should have a thorough knowledge of the principles of organic and physiological chemistry. They must have had at least three years practical experience in physiological or biological chemistry. Open to men and women, non-resident and non-citizens, subject to the usual rule giving preference in certification to citizens and residents of New York state.—Bacteriologist and assistant bacteriologist, State Department of Health. Two lists will be established as a result of this examination: one eligible to appointment as either bacteriologist or assistant bacteriologist at a salary of \$2000, open only to men who have the degree of doctor of medicine, the other eligible to appointment as assistant bacteriologist only at salaries ranging from \$1300 to \$1500, open to both men and women. Applicants should have a thorough knowledge of the principles of bacteriology and must have had considerable practical experience in the bacterial diagnosis of infectious diseases and a general knowledge of clinical microscopy and of gross and histological pathology is desirable.—Assistant chemist, Agricultural Experiment Station, Geneva, Salary \$1200. There are two vacancies. For the first, candidates must be college or university graduates with special training in chemistry including advanced analytical chemistry, analysis of agricultural materials such as fertilizers, feeds, crops, etc., together with some training in the microscopic identification of vegetable tissues with special reference to the constituents of feeds. For the second vacancy the requirements are similar to those for the first except that training in microscopical identification is not required. Open to non-residents, subject to usual rule.—Chief surveyor, Conserva-

tion Commission Salary \$2,400 The appointee to this position must have had wide experience as a surveyor of Adirondack lands He is called and is relied upon as an expert witness in title disputes and he must therefore have had wide experience in Adirondack surveys including experience in running boundary lines

A SOUTH American Expedition which will work under the joint auspices of the Field Museum of Chicago and the New York Museum of Natural History has sailed on the United Fruit liner *Metapan* going first to La Paz Bolivia From La Paz the party will cross the Andes by pack train and descend into a section of Bolivia which is entirely new to the collector The party will descend either the Beni or the Mamore Rivers, and eventually reach the Amazon by the Madeira The party consists of Messrs Luc Garnett Day Alfred M Collins George K Cherric Robert H Becker and W L Walker Mr Day has traveled in the Orient and in Brazil Mr Collins during the past two years has made hunting trips in South Africa and the Arctic regions north of Siberia Mr Cherric accompanied the Roosevelt expedition last season, and has collected for the British Museum the New York Museum of Natural History and the Field Museum of Chicago Mr Robert H Becker has just returned from the Amazon Valley and southern Brazil where he collected for the Field Museum

DR FRANK BILLINGS Chicago has been invited to deliver the Yano lecture for 1915 The *Journal of the American Medical Association* gives the list of previous lecturers, which is as follows

1896 Sir William MacEwen regius professor of surgery University of Glasgow "Surgery of the Brain"

1897 Christopher Heath professor of clinical surgery University College London "Congenital Malformations Aneurism and other Surgical Topics"

1898 Thomas Clifford Allbutt, FRS, regius professor of physics, University of Cambridge, England "Diseases of the Heart"

1899 Nicholas Senn professor of surgery,

Rush Medical College, Chicago "Topics in General Surgery"

1900 Sir Michael Foster, professor of physiology Cambridge, England "History of Physiology"

1901 Sir Malcolm Morris surgeon, skin department, St Mary's Hospital London "Social Aspects of Dermatology"

1902 Sir Charles B Ball, regius professor of surgery University of Dublin "Diseases of the Rectum"

1903 Oscar H Ellis Philadelphia, Pa "Dislocations and Fractures Involving Larger Bones"

1904 William H Welch professor of pathology Johns Hopkins University, Baltimore "Infection and Immunity"

1905 Sir Patrick Manson "Tropical Diseases"

1906 John C McVal "Practical Hygiene, Epidemics and Preventive Medicine"

1910 Reginald Heber Fitz Hersey professor of theory and practice of medicine, Harvard University Boston "A Consideration of Some Features of the Lymphatic System"

1911 F Fuchs professor of ophthalmology, University of Vienna "Importance of Ophthalmology in its Relation to Systemic Disease"

1913 Edward Albert Schaffer, professor of physiology University of Edinburgh "Internal Secretion"

UNIVERSITY AND EDUCATIONAL NEWS

THE sum of \$2470,000 was obtained for Wellesley College in the fourteen months just ended according to a statement given out by the treasurer Of this amount \$430,000, including a conditional pledge of \$200,000 from the General Educational Board was raised before the fire of March 17 when College Hall was burned The remaining \$2,000,000 includes a pledge from the Rockefeller Foundation of \$750,000 Only three gifts of over \$10,000 have been received since last August One of these was made but ten days ago and was a gift from Mr Carnegie of \$95,000 for the enlargement of the library

THE Massachusetts Institute of Technology has received in gifts during the past year the sum of \$400,000, besides two items wherein the institute is residuary legatee, and the amounts have not been determined Following is the list Bequest of Caroline L W

French (outright), \$100,000, (residue), \$100,000, Lucius Tuttle, \$50,000, Nathaniel Thayer, \$50,000, William Endicott (residue), \$25,000, Matilda H. Crocker (outright) \$20,000, (residue), \$20,000, Mrs. W. A. Abbe, \$10,000, gift for George Henry May scholarship \$10,000, gifts for research in a number of amounts, \$10,000.

OHIO UNIVERSITY Athens, Ohio has just put into service its \$15,000 electric light and power plant. The boiler plant was previously installed in connection with the central heating system, and the above sum covered the cost of other station equipment, underground cables connecting the station with the various buildings and the necessary transformers. The total capacity of the plant is nearly 400 horse power.

THE complete report of the proceedings of the First National Conference on Universities and Public Service has been printed, extending to 350 pages. Copies will be sent free to trustees and other university officers, public officials, editors and librarians. To others it will be sent at cost of publication on application to Edward A. Fitzpatrick, Box 380, Madison, Wisconsin.

H. J. PATTISON has resigned as president of the Maryland College and Station to take effect July 1, 1915, recommending in his letter of resignation the abolishing of the office of president and the substitution of an administrative commission consisting of a director of college work, the director of the station and the director of extension work. This plan is under consideration by the board of trustees.

DISCUSSION AND CORRESPONDENCE

FRATERNITIES AND SCHOLARSHIP

THE communication on "Fraternities and Scholarship" published in a recent number of *SCIENCE*¹ touches a problem of decided interest—the relation of fraternities to the welfare of our higher institutions of learning—and one which has received much attention during the past few years, particularly in the univer-

sities and colleges of the south and west. The treatment of the question by the writer who happens to be the assistant dean for men in the University of Illinois, although presented in a very "readable" form leaves much to be desired however from even an elementary statistical standpoint, and the reader may well hesitate as to the conclusions to be drawn from the data presented, beyond the idea that fraternities may be taught to appreciate the high grades which are assumed to represent scholarship. Perhaps the demonstration of a proposition of this nature is sufficient for the opportunity to thus influence men separated into groups competing with one another, goes far toward justifying the existence of such groups even though they may have certain shortcomings.

While among all men students (2,600) there is an increase in the average grade from 81.1 per cent² for the first semester of 1909-10 to 82.3 per cent for the second semester of 1913-14 and among fraternity men (700) from 78.7 per cent to 81.9 per cent for the same period, the actual increase during the five years is less inasmuch as average second semester grades are in every case higher than first semester grades of the same college year, a result undoubtedly due to the elimination of the poorer students at the end of the first semester. Therefore similar semesters should be compared and the gain is from 81.4 per cent to 82.3 per cent for all men students—relatively 1.11 per cent—and from 79.7 per cent to 81.7 per cent for fraternities—relatively 2.51 per cent.

This is really a small increase to result from a five year propaganda and when taken into consideration with other factors which may have been instrumental in bringing about the result one might wonder as to whether the smoke denoted a fire. The plotting of graphs with relatively long ordinates often conveys a misleading impression.

For the second semester of 1910-11 to the second semester of 1913-14 there is practically no gain for the average grade of all students while fraternity students exhibit a gain ap-

¹ *SCIENCE*, October 16, p. 542.

² Approximations from the published chart.

proximating 17 per cent relatively. Consequently the non fraternity graph—which unfortunately was not published—must have tended downward. The interpretation of this result seems not to have been considered in the paper and if we accept the interpretation of the data as a whole as due to the greater interest by fraternities in grades the downward movement of the plotted line is undoubtedly due to the transfer of men to the one group at the expense of the other group. Thus one might well regret that there were not subdivisions Alpha Beta, Gamma, etc., in the non fraternity group in order to see if the competition engendered would not raise the average grade of all, instead of permitting one to draw on the other for resources.

The statement is made that

in 1909 the chapters were widely scattered up and down the scale, and in 1914 they are closely grouped around the fraternity average. This fact means undoubtedly that during the interval between these years the fraternities have intensified their attention to scholarship.

Such an opinion evidently based on the range between chapters with the maximum and minimum grades which happens to be smaller in 1914 is of course no criterion of "scatter" as ordinary inspection should have demonstrated. Computing the coefficient of variation based on chapter units it may be found that this has a value in 1909 of $2.44 \pm .99$ per cent and in 1914 a value of $2.02 \pm .95$ per cent a negligible difference.

It would have been of considerable interest to have presented data for a discussion of the possible effect the increased interest by students in their marks might have had on grading by the faculty although the latter will deny it and even charge that such a suggestion is heresy. Nevertheless it is not at all impossible that the average gain of 1.11 per cent for all students is connected with a factor of this nature however unconsciously the result may have been brought about.

The whole question as to the value of grades as a criterion for scholarship and efficiency in our higher institutions of learning, particularly where based on frequent examinations

throughout the semester, is still an open one, although several interesting papers bearing on the subject have been published. While the individual who would normally "loaf" is thus compelled to retain bookish facts temporarily, there are others in which a distaste for a subject results from such methods. It is evident however that until the grade of instruction in our secondary schools is brought to a much higher standard, we are not in a position to adopt the plan of the German universities and require a single examination period as a preliminary to the conferring of the degree.

The publication of data relative to efficiency in college instruction is to be commended, but the interpretation of the facts will often present many difficulties. The methods of correlation are adapted to solving numerous problems in pedagogy, and it is to be hoped that not only from the University of Illinois but also from a large number of other institutions may data be presented with a clear mathematical treatment.

SENTIMENT VERSUS EDUCATION

FOR many years our principals in secondary schools have been dinning into the ears of the teachers the order to teach, not to "hear recitations." The same bureaucrats have urged the teachers to help the dull ones, letting the bright ones find their own way. It has resulted that by the time the teacher has gone through the five formal steps the bright students know enough to make a passable recitation the next day at least if the teacher proves as "helpful" as the custom of the school requires. The dull ones know that the matter will be gone over and over again and they see no necessity to study. The teacher has displaced the text book.

Our pupils do not secure the power to get the meaning of any passage more complex than what we find in the daily paper or popular novel. This is partly due to the fact that the teacher is ordered to use "simple language, the language of all great writers."

We have to define efficiency by "work out divided by work in." The teacher has also replaced the dictionary.

Our school work in what is called, from custom, reading seems to consist in reciting some "pieces," very ultra modern, calling for some acting and a little thought. Later the pupils are required to learn what some critic has said about the great works, with perhaps extracts from the professor's doctorate thesis. It is then certain that the pupil will not read any of the books which he has heard called classics.

A teacher found that his pupils could not get what was in the book. They said "Why do the books not present the matter as you do?" He wrote the book, he reported that the reviewers said that it was about as dry a book as they had ever seen.

THE COTTON WORM MOTH

I WAS interested in Professor Fernald's note on the cotton worm moth in your issue of November 27. Professor Fernald reports that few of these moths were taken in Massachusetts in 1912. Now in 1912 we had a great flight of them here, the only invasion on a large scale that I have heard of in this locality. They were here by the tens of thousands, literally covering the ground for a space of 100 square feet or so under some of the street lights.

The moths arrived on the night of October 10, the night watchman in the village told me they came in all at once at about 3 A. M. and flew for a time in such swarms round the electric lights "that you couldn't see the lights for the moths." They were reported in large numbers in at least one other village near here, and my father who was then living in London, Ontario, wrote me that there had been an invasion there which arrived two or three days earlier than ours here, but which must have been on the same large scale as to numbers.

It would be interesting to know whether

these were parts of the same front, or separate swarms moving independently.

In 1913 I saw none here, but during the past autumn there were a few specimens, though I have no record of the date of their appearance.

METEOROLOGICAL OBSERVATIONS IN GERMANY

A LETTER dated Berlin, November 30, 1914, from Professor Dr. Gustav Hellmann, director of the Royal Prussian Meteorological Institute in Berlin, advises us that the usual regular observations are being maintained without interruption throughout the German Empire. So far as the internal weather forecasts for Germany are dependent upon cable reports from foreign countries they are made with difficulty, all such reports are at present interrupted, even those from Iceland since the latter come over a Danish cable that lands at Aberdeen where they are suppressed and are not permitted to reach even Copenhagen. The regular though belated arrival of the *Meteorologische Zeitschrift* together with other scientific publications show that the German scientific world is far from suspending its existence during its present struggle.

G. ABBE, JR.

SCIENTIFIC BOOKS

An Account of the Mammals and Birds of the Lower Colorado Valley with Especial Reference to the Distributional Problems Presented. By JOSEPH GRINNELL. University of California Publications in Zoology, Vol. 12, No. 4, pp. 51-204. Pls. 3, 13, 9 text figures. March 20, 1914.

The report before us gives the results of an expedition undertaken in the spring of 1910 by the California Museum of Vertebrate Zoology. Since the founding of this museum by Miss Annie M. Alexander in 1908, Grinnell and his staff have spent much of their time in the field, accumulating extensive series of specimens, representing the fauna of California and adjacent states, and

of the coast region as far north as Alaska. This valuable material has been collected largely with a view to the study of geographic variation. Throughout that time, and indeed for a much longer period, the author of the present report has been active in describing and subdividing species of Pacific Coast birds and mammals.

A considerable proportion of the vertebrates of this region are represented in different parts of their range by different local races, for which the term "subspecies" has gained general acceptance. Indeed the process of "splitting" in these groups has been carried to such lengths that a large majority of the birds and about three fourths of the mammals listed in the paper here considered are designated by trinomials. Outside of taxonomic circles the feeling is sometimes expressed that these trinomials stand for more or less fictitious entities the product of minds in which the passion for detecting differences has almost reached the stage of paranoia. In quite a different spirit is Bateson's recent advice to the systematists to "subdivide their material into as many species as they can induce any responsible society or journal to publish," since "the collective species is a mere abstraction convenient indeed for librarians and beginners but an insidious misrepresentation of natural truth."¹ Whether these ultimate subdivisions are termed species or subspecies is, of course, a matter of secondary importance. The main thing is that they should be described and named.

It is probably no mere accident that several of the leading exponents of the "isolation" theory of specific differentiation have done much of their field work on the Pacific Coast of North America. Here the subdivision of the earth's surface by means of natural barriers is carried to an extreme probably not elsewhere found within the limits of the United States. It is true that in many cases the areas thus marked off differ very greatly in their climatic conditions, as witness the abrupt change which we encounter in crossing the

mountains from the Mojave Desert to the orange belt of southern California. Any specific differences which are met with on the opposite sides of such a barrier might be attributed to environmental differences acting directly or indirectly. Such cases do not, of course, prove anything as to the efficacy of isolation *per se* in giving rise to divergent descent lines.

In the lower Colorado River, however, Grinnell finds what he regards as a critical instance. Here is a river, bordered on each side by a vast expanse of desert, uniform in its character for great distances, whether to the right or left. Considered as a physical environment, the California side of the river is identical with the Arizona side. Yet of the 23 species of rodents collected in the valley of the Colorado by the museum expedition of 1910 Grinnell and his party found 8 which were absolutely restricted to one or the other side of the river. These last were all strictly desert dwelling forms which probably never visit the water's edge. On the other hand, the inhabitants of the lower reaches of the river bottom were found to be in every instance common to the two banks.

The case upon which the greatest stress is laid is that of two species of ground squirrel belonging to the genus *Ammospermophilus*. Twenty four specimens of *A. harrisi harrisi* were captured at scattered points on the Arizona side of the river, while seventeen specimens of the closely related *A. leucurus leucurus* were taken on the California side, the two occupying the same "ecologic niche" in their respective territories. In no case was a single individual found on the "wrong" side of the river. These two species were seen at points only about 850 feet apart in a direct line. Commenting on this case, Grinnell remarks:

The sharp separation of the ranges of [such] nearly related vertebrates by a barrier of such narrow width is, to the best of the writer's knowledge, not known elsewhere in North America.

The author makes the assumption common to both Lamarckians and Natural Selectionists that morphological differences must, in some

¹ Bateson, "Problems of Genetics," Yale University Press, 1913.

way, result from environmental differences. But, in this instance, "the climatic features (zonal and faunal, as well as associational) are identical on the two sides of the river." Therefore, it is "reasonable to presuppose separate and rather remote centers of differentiation, and convergent dispersal through time and space which brought the resulting types to the verge of the river, beyond which they were unable to spread." It is needless to point out that hypotheses exist, *e g* that of "mutation," which do not invoke the aid of environmental differences to account for all specific change. According to such a view the 'remote centers of differentiation' could be dispensed with.

If as Grinnell believes the two sets of animals "have undoubtedly descended from ancestral lines, which have invaded the territory from the two opposite directions" already specifically distinct we can not see the force of the conclusion that adequate ground is afforded for the belief that intervention of barriers is a prime factor in the differentiation of species." All the evidence shows in this case is that the barrier has kept these species apart. It may have had nothing to do with their differentiation as species. Indeed, in the absence of experimental evidence we can not even affirm with certainty that any physical barrier has been necessary for the continued maintenance of their specific distinctness. It is not impossible that a high degree of sterility would be found to exist between the California and the Arizona species. Nevertheless, the facts, as described are of great interest. Further expeditions should be sent into the valley of the Colorado for the express purpose of testing some of these important questions. And the work should be done before nature's original scheme of distribution has become hopelessly muddled through man's agency.

Grinnell recognizes "three distinct orders of distributional behavior as regards terrestrial vertebrates." First,

every animal is believed to be limited in distribution *seasonally* by greater or less degree of temperature, more particularly by that of the reproductive season. When a number of animals (al-

ways in company with many plants similarly restricted) approximately agree in such limitation, they are said to occupy the same life zone.

Throughout this and many other papers by the same author the "life zone" conception plays a prominent rôle. The zones recognized by C Hart Merriam are adopted by Grinnell and their existence accepted as a fundamental datum, without the necessity of their being justified to the reader. The author believes following Merriam, that the position and extent of these "zones" is determined by temperature conditions. Yet it is obvious that, throughout considerable portions of the continent, the details of temperature distribution are not known with any approach to precision. Thus the actual criterion which the field zoologist falls back upon in any given case is the character of the fauna and flora which he finds associated together. The presence of certain species shows him that he chances to be in this or that 'life zone.' It is assumed though apparently seldom verified, that wherever these particular species occur in conjunction the temperature conditions are in some essential respect similar.

It would seem *a priori* that in traveling along a uniform gradient from a region of higher to one of lower average temperature, or vice versa one would continually pass into and out of the ranges of species which found their limits of physiological adaptability at different points along the line. One would scarcely expect to encounter critical points where the fauna and flora as a whole, or at least the most characteristic members of it were suddenly replaced by a quite different assemblage. Yet this is the essence of the "life zone" conception.

It would be foolhardy, indeed for a zoologist of limited field experience to criticize this conception. It is doubtless based upon extensive and accurate observations and represents real facts. But unfortunately they are, in a high degree, facts which, by their very nature, are scarcely communicable to most biologists. Before the life zone conception can be of much service to the average student of evolutionary problems it will have to be expressed in terms

which he is able to comprehend without making extended explorations, under the personal escort of one of the initiated. Until then, such expressions as "Upper Sonoran," "Transition" and the like will be to him mere empty names, or at best, they will recall to his mind certain colored areas, on a map of North America, the boundaries of which seem to have been chosen quite arbitrarily.

The second type of "distributional behavior" recognized by Grinnell is that which he terms "faunal." The various life zones are each subdivided into a number of "faunal areas" (or, more simply, "faunas"), "on the causative basis of relative uniformity in humidity." We must at the outset, question the wisdom of appropriating the word "fauna" for use in such a restricted and technical sense, particularly since quite a variety of meanings have already been attached to it by previous writers.

Grinnell regards it as "probable that every species is affected by both orders of geographic control" (i. e. temperature and humidity), though believing the influence of temperature to be the greater of the two. While this belief in the role played by humidity does not appear to be based, in any single case upon exact observational data it would surely be unreasonable to throw it out of consideration on that account. One does not require an accurate hygrometer to sense the difference in humidity between the atmosphere of the red wood district of northwestern California and that of the Mojave Desert. We can not help wondering, however, whether sufficient care has been taken to disentangle the effects of atmospheric humidity from those of rainfall and soil humidity. Regions of high atmospheric humidity may be regions of high rainfall as well, but the reverse is not infrequently true, as witness the coast of southern California. It is a matter of common knowledge that vegetation is far more affected by the though the latter is also an important factor in moisture of the soil than by that of the air,

Since the distribution of animals is so largely conditioned by that of plants, the indirect effects of rainfall and soil humidity upon the fauna of a region are beyond doubt. With rodents and other burrowing animals it seems not unlikely that the effects are much more direct.

The third "category of distributional control" recognized by Grinnell is that which he terms "associational." By "associations" he means "tracts of relatively uniform environmental condition, including their inanimate as well as living elements." They are, of course, subdivisions of a "fauna" just as "faunas" are subdivisions of a "life zone." The "association" proper to a species represents its habitat in the narrower sense, as distinguished from its geographical range. It is here that we find the most conspicuous correlation of the 'so called adaptive structures of animals with certain mechanical or physical features of their environment."

The associations considered in the present report are all (except one) named for some characteristic plant and, in fact, the term itself is borrowed from the botanists, by whom this conception was first developed. Ten of these associations are distinguished in the lower Colorado Valley traversed by the expedition under consideration. This whole region, however, belongs to the "Colorado Desert Fauna" and to the "Lower Sonoran Life-Zone."

The report contains a considerable fund of valuable ecological detail, palpably based upon careful observation, and in a large degree co-ordinated so as to lead to conclusions, or at least to definitely formulated problems. In this last respect it stands in gratifying contrast to the recent output of some of the professed exponents of the science of ecology. A highly interesting special instance is Grinnell's discussion of associational restriction, as illustrated by the various species of pocket mice (*Perognathus*). Here a truly quantitative mode of treatment has been resorted to, and very instructive results reached, despite the comparatively small number of individuals.

* Transeau (*American Naturalist*, December, 1905) contends that the controlling influence for plants is the ratio of rainfall to evaporation.

If nothing more, they point out a promising method of detecting and measuring associative preferences among animals which may be readily trapped.

The evolutionary theories of Darwin and Wallace were largely founded upon personal observations of geographical distribution. The modern student of genetics, on the contrary, carries on his studies for the most part in the laboratory and the breeding pen. It is significant, therefore, that Bateson² perhaps the foremost living Mendelian, devotes a considerable portion of a recent volume to the problems of geographic variation. And one can hardly read that volume attentively without being convinced that the field naturalist holds the key to some of the most important secrets of nature. It is not improbable, therefore, that works of the sort here reviewed will come to receive more serious consideration from those who are concerned primarily with the problems of organic evolution.

FRANCIS B. SUMNER

SCRIPPS INSTITUTION FOR
BIOLOGICAL RESEARCH,
LA JOLLA, CALIF.

Chemical Technology and Analysis of Oils, Fats and Waxes. By DR. J. LEWKOWITZCH. Edited by GEORGE H. WARBURTON. Vol. II. 1914. Pp. 994. \$6.50.

The first volume of this work appeared in this country while the author lay dead. While the death of an eminent chemist is always to be regretted in this case there was an additional reason for regret—the delay, or worse yet the possible non appearance of the remainder of the treatise. The delay has been so slight as not to be noticed and the editorial work has been most satisfactorily performed by Mr. Warburton, who for seventeen years was associated with Dr. Lewkowitsch in his analytical practice.

This volume has been increased in size by thirteen per cent, important additions have been made in the articles on linseed, tung, soy bean, coconut oils and candelilla wax, as

well as minor additions to other portions to bring them thoroughly up to date.

The work may fairly be described as monumental, nothing would seem to have escaped attention. Even the toxicity of the different chlorides with two atoms of carbon has been given as having a bearing on their technological uses.

Notwithstanding the very full table of contents the reviewer misses and must wait a year perhaps for an index which it would seem advisable to include in each volume. Similarly the reviewer is inclined to question the advisability of including the large amount of statistical matter about the commercial side. That, it would seem might well form the subject of a single volume like the author's "Laboratory Guide to the Fat and Oil Industry" and be revised and brought up to date more frequently. If the work continues to grow as it has in the past, it would seem worth while to consider its publication by some society as its compeer "Beilstein" has been taken over by the German Chemical Society.

A. H. GILL

SPECIAL ARTICLES

THE NITROGEN NUTRITION OF GREEN PLANTS

It is the teaching of botanists that green plants obtain their nitrogen chiefly in the form of nitrates, though ammonium salts may be utilized to some extent by certain plants at least. Exceptions to this general rule are those plants provided with root tubercles (and bog plants and others which have mycorrhiza). These plants obtain their nitrogen in the form of organic compounds made for them by the bacteria growing in the tubercles.

That nitrogen circulates throughout the structures of plants in organic combination is certain. There does not appear to be any reason why similar compounds which are soluble and diffusible (amino acids?) should not be taken up through the roots of plants and utilized as such. It appears to the writer that this must very probably be the case. Arguments in favor of this view are

1. The nitrogen nutrition of the leguminous

plants and others with root tubercles is of this character

2 The close symbiosis between "Azotobacter" and similar nitrogen absorbing bacteria and many species of algae is well known

3 The increased production of timothy and other grasses when sown *along with clover* not merely following, has been demonstrated

4 The vigorous growth of plants in soil's very rich in organic matter. Such material inhibits the growth of the nitrous nitric bacteria when grown in culture and may do so in soil so that nitrates may not account for this vigorous growth

5 As a general rule the most fertile soils contain the most bacteria

6 The doctrine that nitrates furnish the nitrogen to plants was established before the activities of bacteria in the soil were suspected and should be re-investigated under conditions absolutely controlled as to sterility. It is probably true in large part, but may not be the exclusive method

It would seem that one of the chief functions of bacteria in the soil is to prepare soluble organic compounds of nitrogen for the use of green plants. It does not appear to be really necessary that organic nitrogen compounds decomposing in the soil must be "ammonified," "nitrified" and "nitrated" as is now generally held since Winogradsky demonstrated the activities of bacteria in these lines to account for the presence of nitrates in the soil

Experiments have been made by various observers in growing seedling plants of different kinds in water culture with one, or in some cases several of the amino acids as sources of nitrogen. Most of these experiments have been disappointing. Plant proteins are not so different from animal proteins, nor plant protoplasm (apart from the chlorophyll-containing portions) from animal protoplasm as to lead one to suppose that it could be built up from one or two amino acids any more than animal protoplasm can. The writer is strongly convinced from investigations on this subject for several years that it should be thoroughly investigated. It will require

careful experimentation and possibly rather large funds to provide the amounts of amino acids that would probably be needed, but might result in a decided change in current ideas of soil fertility and in the use of nitrogen fertilizers

CHAS B MORREY

OHIO STATE UNIVERSITY

THE PHILADELPHIA MEETING OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

THE sixty-sixth meeting of the American Association for the Advancement of Science and of the affiliated national scientific societies was held in Philadelphia December 28, 1914, to January 2 1915. Houston Hall at the University of Pennsylvania was the headquarters and most of the meetings of the sections and affiliated societies were held in the various buildings of the university.

The registered number of members in attendance was one of the largest in the history of the association, being 1086. The number for the affiliated societies could not be definitely ascertained. A number of institutions sent delegates to the meeting and ten foreign associates were elected for the meeting. The following affiliated societies met during the week:

American Physical Society
The Geological Society of America
Paleontological Society of America
American Alpine Club
American Society of Zoologists
American Society of Naturalists
American Association of Entomologists
Entomological Society of America
Botanical Society of America
American Phytopathological Society
Society for Horticultural Science
Sullivant Moss Society
American Microscopical Society
American Fern Society
American Anthropological Association
American Folk Lore Society
American Psychological Association
Southern Society for Philosophy and Psychology

Society of American Bacteriologists
American Federation of Teachers of the Mathematical and the Natural Sciences

American Nature Study Society
School Garden Association of America,
Society of Sigma Xi

The formal opening of the association took place on Monday evening at the first general session when the meeting was called to order by the retiring president, Dr Edmund B Wilson. Dr Wilson introduced the president of the meeting, Dr Charles W Eliot. After the welcoming address and the reply by the president the retiring president delivered the annual address, on "Some Aspects of Progress of Modern Zoology." This meeting was followed by a reception to the members of the association and affiliated societies by Provost and Mrs Smith in the university museum.

Two public lectures complimentary to the citizens of Philadelphia and vicinity were given during the week. The first was by Dr Dayton C Miller on "The Science of Musical Sounds" on Tuesday evening in the Asbury M E Church, the second lecture was by Dr William H Nichols on "The War and the Chemical Industry" on Wednesday at the same place. Both of these lectures were well attended.

The sections and affiliated societies held their meetings morning and afternoon during the week and many important papers were read.

Numerous smokers and dinners were held by the various societies. The University of Pennsylvania very generously furnished luncheon each day in the gymnasium for all of those in attendance.

The vice presidential addresses given before the sections were as follows:

Section A "The Object of Astronomical and Mathematical Research," by Frank Schlesinger.

Section B "Recent Evidence for the Existence of the Nucleus Atom," by A D Cole.

Section C "Theories of Fermentation," by C L Alsberg.

Section D "Safety Engineering," by O P Hood.

Section E "The Relief of our Pacific Coast," by J S Diller.

Section F "The Research Work of the Tortuga Laboratory of the Carnegie Institution of Washington," by Alfred G Mayer.

Section G "The Economic Trend of Botany" by Henry G Cowles.

Section H "The Function and Test of Definition in Psychology," by Walter B Pillsbury.

Section I "The Social and Economic Value of Technological Museums," by Judson G Wall.

Section K "The Classification of Nervous Reactions," by Theodore Hough.

Section L "The American Rural Schools," by P P Claxton.

Section M "The Place of Research and of Publicity in the Forthcoming Country Life Development," by L H Bailey.

The most important actions of the council were as follows:

The election of 256 members and 620 fellows.

The committee on policy recommended the following resolutions which were adopted by the council:

Resolved That the Committee on Policy shall consist of the president, the permanent secretary and nine other members three to be elected annually. Non attendance at the meetings for one year to constitute resignation from the committee.

Second The following committee was elected to serve for one year: Messrs A A Noves R S Woodward and J McKeen Cattell to serve for two years, Messrs D F McDougall W J Humphreys and F L Nichols, to serve for three years, Messrs H L Fairchild and F C Parker.

Third Dr Stewart Patten was elected to fill the vacancy on the committee caused by the death of Dr C S Minot.

Fourth Dr Edward S Morse and Dr T C Mendenhall were made life members of the association under the terms of the Jane M Smith Fund.

Fifth Herbert A Gill was appointed as official auditor for the association.

Sixth That all committees of the association which have not reported for two years be discontinued.

Seventh The nomination by the sectional committee of Section I of Mr Elmer F Rittenhouse as a fellow and vice president of that section was approved.

Eighth The nomination by the sectional committee of Section D of Dr Frederick W Taylor as vice president of that section was approved.

Ninth There was voted an appropriation of

\$1,800 for the salary and expenses of the associate secretary for the Pacific Coast Division for the coming year and \$400 for use in an effort to increase the membership and any sum received from entrance fees in excess of \$400 to be devoted to the same purpose.

Professor Pickering gave a résumé of the work of the committee on expert evidence and a report of progress on the work of the committee of one hundred on scientific research.

The following names were added to the Pacific Coast Committee:

Professor Henry Landes, University of Washington; President Fnoch A. Bryan, State College of Washington; President M. A. Brannon, University of Idaho; Professor Maxwell Adams, University of Nevada; Professor Joseph F. Merrill, Director of the School of Mines, University of Utah.

The following resolution from Section K was referred to the committee on policy:

Resolved, That this association establish a standing committee of five members to be known as the Committee on the Protection of Scientific Research, that this committee from time to time prepare and publish in the name of the association such statements and resolutions as it may consider necessary in the education of the public concerning the value of animal experimentation in the advancing of the medical and biological sciences.

The two following resolutions were adopted:

Resolved, That there be authorized a finance committee of three of which the treasurer shall be a member and chairman.

Resolved, That a committee of seven be appointed on the administration of the income of the research funds of the association, the committee to be the five chairmen of the subcommittees already formed by the committee of one hundred on scientific research, namely Messrs E. C. Pickering, C. R. Cross, E. W. Brown, T. W. Richards and E. L. Nichols, and in addition Messrs F. G. Conklin and R. A. Harper.

Messrs H. C. Cowles, Henry B. Ward and Dr. Stewart Paton were elected members of the council for three years.

A minute in memory of Charles Sodgwick Minot presented by Mr. J. McKeen Cattell was adopted by a rising vote.

The council at its final meeting passed resolutions extending thanks to Provost Smith, of the University of Pennsylvania, and to all the organizations and institutions who did so much for the comfort and entertainment of the members of the association.

At the meeting of the general committee, the following officers were elected:

President, W. W. Campbell, University of California.

See presidents

Section A, A. O. Leuschner, University of California.

Section B, Frederick Slate, University of California.

Section C, W. McIlherson, Ohio State University.

Section D, Brien J. Arnold, Chicago.

Section E, C. S. Flosser, Ohio State University.

Section F, V. L. Kellogg, Stanford University.

Section G, W. A. Setchell, University of California.

Section H, G. M. Stratton, University of California.

Section I, Geo. F. Kunz, New York.

Section K, I. P. Gay, University of California.

Section L, I. P. Gubberley, Stanford University.

Section M, Eugen Davenport, University of Illinois.

General Secretary, Henry Skinner, Philadelphia.

Secretary of Council, W. F. Henderson, Ohio State University.

C. E. A. Winslow was elected secretary of Section K to fill an unexpired term of two years.

Dr. I. O. Howard was again reelected permanent secretary for a term of five years.

The committee voted to hold the summer meeting at San Francisco, August 2 to 7, and the next winter meeting at Columbus, Ohio, from December 27, 1915, to January 1, 1916.

A convocation week meeting in which all scientific societies are invited to join is recommended for New York City in 1916-17, and a meeting in 1917-18 to be held in Toronto or Pittsburgh.

E. L. WORSHAM,
General Secretary

THE great French scientist Poincaré just before his death two years ago, described an atom before the French Physical Society in these words

Each atom is like a kind of solar system where the small negative electrons play the rôle of planets revolving around the great positive central electron which takes the place of our sun. Besides these captive electrons there are others which are free and subject to the ordinary kinetic laws of gases. The second class are like the comets which circulate from one stellar system to another establishing thus an exchange of energy between distant systems.

Such an atom is a world in itself and strangely different from the kind we learned about in our text books twenty years ago. One of the much used chemists of that day put it in this way

An atom is the smallest portion of matter that can exist; it is incompressible, indivisible and in itself unchangeable.

How has this great change of view come about? How has the indivisible unit evolved into the complex microcosm we now imagine? Time would fail us to trace all the steps of the way; we will attempt only to bring out some of the considerations which have in the past three years led many of our foremost thinkers to believe in that particular type of atom which we may call the nucleus atom. This type is similar to that which Poincaré pictured except that the central body is much smaller—very

¹ Address of the vice president and chairman of Section B Physics, of the American Association for the Advancement of Science at Philadelphia, December 29, 1914.

small indeed as compared with even the minute electrons which circulate about it.

We will recall first several of the discoveries which have forced us to abandon the idea of an indivisible atom. The fundamental one was Sir Joseph Thomson's discovery of the electron. In studying the nature of the cathode rays he found that they consisted of extraordinarily minute particles all exactly alike whatever the nature of the gas within the tube might be. In a series of brilliant experimental studies he was able to show that the mass of one of these electrons was only one eighteen hundredth that of the lightest known atom. Then came Zeeman's discovery² that the separate lines of many spectra are broken up into two or more lines by the action of strong magnetic fields. The study of this effect made it quite certain that light radiation is caused by the rapid vibration of electrons in the luminous body. Therefore electrons must be present in very many kinds of matter—probably in all. The electrons were early proved to carry a negative charge of electricity. Soon they revealed their presence in a great variety of ways and assisted in the explanation of widely different phenomena. But the corresponding positive constituent of matter proved singularly elusive although most diligently sought for and it is only very recently that we seem to have traced it to its hiding place.

Different views regarding the nature of this positive constituent have led to much diversity of opinion regarding the structure of atoms. One of the most successful of these theories is that proposed by Sir Joseph Thomson in 1904.³ He supposed a relatively large positive mass to exist—nearly as large as the atom—with the minute negative electrons distributed through it in such a way as to make the system a stable one. For easy mathematical treatment he assumed the electrons at equal

distances apart in a series of concentric circular rings. To secure stability and illustrate certain atomic properties he supposed these rings to be in rotation. Thomson discussed many such configurations and satisfactorily explained many facts regarding the valency, the position in the periodic system, the electropositive or electronegative character and other chemical properties of different substances.

A modification of Thomson's atom was proposed by H. A. Wilson in 1911.⁴ He supposes each negative electron to be situated at the center of a positive sphere of sufficient size to neutralize it electrically and the atom to be made up of a group of such units, the total number being proportional to the atomic weight. In other words Thomson's one relatively large positive mass is divided up into equal parts, each one containing a single negative electron. The mathematical development of this idea led to the result that the hydrogen atom contains eight such units. The gold atom would therefore contain about sixteen hundred of them.

In the Thomson and the Wilson atoms, the positive portion is diffused throughout nearly the whole volume of the atom, a region about one hundred millionth of a centimeter in diameter. This type of structure has accounted for many atomic properties but has not been very successful in explaining the position of the lines in light spectra caused by vibrations in the atom.

I wish to direct your attention to a more particularly to a type of atom in which the positive charge—equal as before to the sum of the charges of the negative electrons—is highly concentrated at the center of volume of the atom, occupying only an exceedingly small part of the volume. Nagaoka⁵ had discussed the stability of such an atom in 1904. Sir Ernest

Rutherford revived it in 1911 to explain phenomena observed by Geiger and Marsden⁶ and achieved a striking success. The facts observed were these: when α rays were allowed to pass through thin sheets of metal, a small proportion of them were observed to be deflected through very large angles. Rutherford⁷ made a theoretical examination of the results of a single encounter between an α particle and an atom of the concentrated nucleus type and calculated the proportion of the α particles which would be deflected through various angles by such encounters. Geiger⁸ then made a new experimental study of the scattering produced by gold foil and found a very satisfactory verification of Rutherford's formula. From the amount of scattering at various angles the value of the nucleus charge was also calculated. For gold it came out about 100 e . The general conclusion was reached that the nucleus charge is about one half the atomic weight times the charge of an electron. But Barkla⁹ had earlier reached the same value for the sum of the electron charges—which in a neutral atom should equal the nucleus charge—by observations on X rays and the use of a theory developed by J. J. Thomson. According to these views atoms contain only about one sixteenth as many electrons as they do on the theory of H. A. Wilson.

On the assumption that large angles of deflection are sometimes due to single encounters with an atom, large forces must be postulated to swing the α particles so considerably from their paths, forces so large as to require an approach to within an exceedingly small distance from the nucleus center. This distance was calculated to be about $1/3,000$ of the atom diameter. If this is true, the nucleus can hardly have a diameter exceeding $1/5,000$ that of the atom.

The view that an α particle may turn through a large angle as the result of a single encounter was strikingly confirmed in 1912 by some remarkable photographs of the paths of α particles through a gas taken by C. T. R. Wilson.¹⁰ I have here a reproduction of one of these photographs which shows two abrupt bends in the trail of a particle, one of 105° and the other of 43° . This second bend would certainly seem to be a case of single scattering. The astonishing conclusion regarding the small size of the nucleus has been confirmed by some recent experiments of Marsden¹¹ in passing α radiation through a gas.

A theory had been worked out by Darwin that when α radiation entered hydrogen, a few H atoms would acquire from close encounters with the α particles a velocity 16 times that of the striking α particle, corresponding to a range four times that of the radiation. Marsden's experiments were undertaken to test this theory. He passed α rays into hydrogen and observed the scintillations on a zinc sulphide screen placed at various distances. The range of the α particles was found to be 20 cm., but a few scintillations were found when the screen was as much as 90 cm. distant, due seemingly to the rapidly moving H atoms in their recoil from collision with the heavier α particles. This was a striking confirmation of Darwin's theoretical calculations. Calculation by his method showed that the centers of the nuclei during collision were not over 17×10^{-13} cm. apart. This then would be the maximum value of the sum of their radii. This is smaller even than the former result and also smaller than the accepted value of the diameter of an electron.

Thus the nucleus of the atom appears to be extraordinarily minute and this suggests an explanation of the somewhat paradoxical result that practically all of the mass of

the atom seems to reside in the nucleus. For if the size is extremely small its electromagnetic mass would—from the formula $2/3 \frac{e^2}{a}$ —be relatively large. So its mass might be 1,800 times that of the electron (and J. J. Thomson's experiments suggest that no positive carrier has a mass smaller than that amount) provided its diameter were only 1/1,800 that of the electron. From such consideration Rutherford¹² thinks it probable that the *nucleus of the H atom* is, in fact, the long-sought positive electron.

Attention has been forcibly drawn to the nucleus type of atom within the past year and a half by the extraordinary success it has had as interpreted by Bohr, Darwin and Moseley, in accounting for the exact position of lines in the spectra of gases. Their work has also served to bring into the limelight the earlier and perhaps equally striking work of J. W. Nicholson. In November, 1911, he published a paper¹³ in which he assumed the existence of several elements with atoms of very simple and definite structure. One of these he called *nebulium*. In the neutral condition it was supposed to have a positive nucleus with charge $4e$, and around it at equal distances apart in a circular path, rotated four electrons each with unit charge e . It might, however, lose one electron, when it would become positively charged, its three electrons now taking up new positions a third of a circumference apart. Similarly he supposed that the atom might take up more electrons, and have a negative charge.

He discussed mathematically the vibratory motions of such an atom and showed what kind of a spectrum the radiation would furnish. The theoretical analysis of the spectrum of his imaginary element *nebulium* showed that all the characteristic

nebula lines of the Great Nebula in Orion, leaving out those due to hydrogen and helium, could be attributed to the vibrations of the *nebulium* atom except two lines. On the very day he read this paper in England a German astronomer M. Wolf¹⁴ presented a paper in Heidelberg which described the discovery that different lines of this nebula were due to radiation from different parts of the nebula and that these two lines which Nicholson had found exceptional were due to a radiating source different from that of the other lines. Whereas almost all the lines were due to radiation from the bright ring of the nebula, these two lines were caused by radiation from different parts of the nebula that for one of them coming from the dark central space and for the other chiefly from the outer edge of the ring. All other lines had their maximum brightness in the bright ring itself.

Another imaginary substance which Nicholson named *protofluorine* he succeeded in connecting in a similar way with the spectrum of the sun's corona.¹⁵ This atom he supposes to have—when neutral—a nucleus $5e$ with 5 electrons in a circular orbit about it. He analyzes its radiation on the assumption that it gives forth radiation energy in quanta as Planck has supposed. He anticipates Bohr in the emphasis he gives to the idea of constancy of angular momentum in the rotating electrons. His calculations on this *protofluorine* atom account satisfactorily for the existence of fourteen out of the twenty-two lines of the corona spectrum, with an average difference of less than one part in a thousand between observed and calculated values. His calculations also show the magnitude of the positive or negative charge of the atoms originating the various lines. He concludes that in these primitive forms of matter—*nebulæ* and

solar corona—very simple types of atom exist, much more simple doubtless and more amenable to calculation than are the atoms of most terrestrial substances. While the correspondence between his calculated spectra and those observed at Luck Observatory is not so close as is that between theory and observed spectra in the recent work of Bohr, it is important to observe that most of these results are obtained by means of established mechanical principles and without the use of such questionable assumptions as the brilliant young Dane cheerfully and confidently makes.

And now let us consider briefly the work of Bohr. This is set forth in four papers¹⁴ published in the *Philosophical Magazine* between July of last year and March of the present year. He starts with the Rutherford atom, i. e., a minute positive nucleus with its system of electrons revolving about it, the mass of the atom resident chiefly in the nucleus and the number of electrons approximately equal to half the atomic weight. He admits the difficulty of securing stability in such an atom (as compared, for instance, with Thomson's 1904 atom), but thinks that this difficulty can be removed if we admit the insufficiency of the classical dynamics to explain phenomena involving atomic distances, and introduce Planck's quantum into the equations. He claims that this furnishes a basis not only for a theory of atomic constitution but for that of molecules as well. He differs from Nicholson radically in assuming that when in a state of uniform rotation, the electrons do not radiate. This is not in accordance with our ordinary electrodynamics. Each atom, according to Bohr, has a number of "steady states" during which the electrons revolve uniformly and there is no radiation. But in passing from one steady state to another an electron winds inward toward the nucleus with its frequency increasing.

Its acceleration meanwhile causes radiation, until the electrons settle into another steady state and ceases for the time to radiate. In its stable state the angular momentum of every electron is the same. This agrees with Planck's idea of discontinuous radiation and the amount radiated in one emission for a vibrator of frequency ν is $\tau h \nu$ where τ is some integer and h is Planck's "universal constant." Bohr finds the equation for the relation between the frequency, mass of an electron, charge of electron, τ and h . When τ is made 2 in the equation, Balmer's series for hydrogen is obtained, and for $\tau=3$ the infra red series which Ritz anticipated and Paschen found. $\tau=1$ gives a series of lines in the ultra violet and $\tau=4$ and 5 in the infra-red neither of which has yet been observed. The lines observed by Fowler and by Pickering he connects with helium instead of with hydrogen.

From this equation he also calculates Rydberg's number N° and obtains 3.26×10^{15} . Its observed value is 3.29×10^{15} , so that the agreement of theory with observation is satisfactory. The theory further requires that very low gas density be required for numerous spectrum lines and very great gas volume for sufficient intensity. This probably accounts for the fact that 33 lines of the Balmer series for hydrogen can be seen in celestial spectra while only 12 appear in terrestrial (vacuum tube) spectra.

From the work of Barkla and of Geiger and Marsden on the scattering of radiation Bohr accepts the view of van der Broek that the number of electrons in an atom in the neutral state indicates the position of the element in the periodic table. Thus he gives hydrogen one electron, helium two, lithium three, beryllium four, etc. The same number expresses the magnitude of the positive charge on the nucleus.

It is difficult to pass upon the validity of

some of Bohr's assumptions. So high an authority as Jeans¹⁷ calls it "a most ingenious and suggestive, and I think we must add convincing explanation of the laws of series spectra," and yet he adds a little later that the only justification for the assumptions Bohr makes is "the very weighty one of success." Rutherford cautiously observes

The theories of Bohr are of great interest and importance as a first attempt to construct atoms and molecules and explain their spectra

The views of Rutherford and Bohr regarding the structure of atoms are strongly supported by some striking experiments of Moseley published during the past year.¹⁸ His work utilizes the methods worked out by W. H. and W. L. Bragg¹⁹ for measuring the spectra obtained by reflecting X rays from the faces of crystals. Barkla and Sadler²⁰ showed in 1908 that if X-rays from an ordinary tube fall on different metals, "characteristic X rays" are given off—these being different for each metal. Many metals can give out at least two different types of radiation. Barkla called these the "K series" and the "L series" radiations. For each metal the "K" radiation is about 300 times as penetrating as the "L" radiation. Kaye²¹ has shown that an element excited under suitable conditions by rapid cathode rays gives out a considerable portion of the X rays produced in the form of characteristic rays.

Moseley photographed the spectra obtained by using a great variety of different metals as targets for cathode ray bombardment. The X rays so produced were reflected from a crystal face and then fell upon the photographic plate. Spectra of the third order showing fine sharp lines were obtained. Similar results were secured for over forty metals. For the elements of lower atomic weights, each spectrum showed two prominent lines, and the

spectrum of any element was almost exactly like that of the element next below it in the periodic table except that it was shifted in the direction of shorter wavelength by about the distance between its two lines. The radiation was of the "K" type. Thus a close relation was established between the X ray wavelength and chemical properties. Further, the frequency of the principal line was found to be proportional to $(N-a)^2$, where N is an integer and a is a constant equal to about unity. N is called the atomic number of the element. Thus it is 20 for Ca, 22 for Ti, 23 for V, 24 for Cr, 25 for Mn, 26 for Fe, 27 for Co, 28 for Ni, 29 for Cu, 30 for Zn, etc. These numbers are very nearly in the orders of the increasing atomic weights, but more exactly in the order of Mendeleeff's periodic table. The numbers then correspond with the changes in chemical properties more nearly than do the atomic weights. For instance, we have Fe, Co, Ni representing both the chemical order and order of the atomic numbers (26, 27, 28), while Fe, Ni, Co is the order of increasing atomic weights. It thus appears that this atomic number is a more fundamental quantity than is the atomic weight, or as Soddy²² has put it,

It is the nuclear charge rather than the atomic mass, which fixes the position of the element in the Periodic Table.

A. van der Broek²³ had before this suggested that the total number of unit charges on the electrons of an atom is the number representing the position of the element arranged according to increasing atomic weight. But in a neutral atom the sum of the (negative) charges on the electrons should equal the positive charge on the nucleus so that the two statements amount to the same thing.

When the experimental values found for the frequency were compared with those

indicated by Bohr's theory, the agreement was found to be a remarkably close one

With elements of higher atomic weight Moseley obtained spectra whose lines indicated the Barkla "L type" of radiation. The atomic numbers calculated from the positions of the strongest lines of these "L" spectra ranged from 40 for zirconium to 79 for gold. These experiments then give strong support to the hypothesis of van der Broek that the total charge of the electrons of an atom indicates its position in the periodic system. Known elements were found to correspond with all the numbers from 13 to 79 except three indicating that three elements probably remain to be discovered. The wave lengths of the characteristic X-rays from the metal is of the order of $1/1000$ that of visible light (c , about 40 waves in 0.00001 inch).

During the past few months Rutherford and Andrade²⁴ have extended these methods of crystal reflection to the study of radiation from Ra B, Ra C. The γ ray spectrum of Ra B was found to be of the same general type as that of the X ray spectrum from various heavy metals when bombarded by cathode rays. The result for soft γ rays from Ra B shows that its radiation belongs to the "L series" for heavy metals. Moseley's formula applied to the measurement of the lines of the γ -ray spectrum gave $N=82$, which is the atomic number of lead. The atomic weight of Ra B is, however, 214, while that of lead is 207. This difference is nevertheless fully explained by a new generalization of Soddy and Fajans which we will presently notice. The experiments described in the second paper were made with much more penetrating γ -radiation from both Ra-B and Ra-C. This penetrating γ -radiation from Ra-B was found to correspond to the K series for the same metal, lead. The still more penetrating radiation from Ra-C has a line spectrum

of still higher frequency than the K type, for which the name "H" series is suggested. These rays are especially interesting because they have by far the shortest wave-lengths yet known, only about $1/8$ of the wave length of the shortest X ray waves measured by Moseley or about $1/80,000$ of the wave length of sodium light. Rutherford in his comments on these waves very justly remarks, "It is surprising that the architecture of the crystals is sufficiently definite to resolve such short waves."

During 1913 some remarkable work on the relations of radioactive substances to each other has given support to the nucleus atom from an unexpected quarter. Fleck,²⁵ Russell,²⁶ Von Hevesey,²⁷ Fajans²⁸ and Soddy²⁹ have all had a share in this work. They have found that when a radioactive substance ejects an α particle a substance of different chemical properties and different valency results. The new substance lies two columns to the left in the periodic table, has an atomic number two less and an atomic weight about four less than the parent substance. If however the radioactive substance ejects a β particle or electron, the new substance is one column to the right in the periodic table, increases one in atomic number, and does not change in atomic weight. Plainly then two or more elements may occupy the same position in the periodic table, for if an element loses in succession—in any order—two β -particles and one α particle, its atomic number will be again the same as it was at first. Thus Ra D has the atomic number 82, it loses a β particle and becomes Ra E with atomic number 83. This loses another β -particle and becomes Ra-F with atomic number 84, this finally loses an α particle and becomes lead, with the original atomic number 82. The series Ur1, Ur X1, Ur X2 and Ur2 is of the same kind, except that the particles are ejected in the reverse

order, α , β , β . So the old difficulty of finding places in the periodic table for the 34 radioactive substances now known has disappeared, since they have but ten different atomic numbers and require therefore but ten places in the periodic table. Soddy has introduced the term isotopes to designate two elements occupying the same place in the table. Isotopes are chemically inseparable and probably have identical spectra, but they have different atomic weights.

It is evident that much remains to be done before we have very definite ideas of the structure of the nucleus atom. Many questions are entirely unanswered. For example, in how many rings do the electrons lie? For hydrogen and helium as for nebula and protofluorine (if they exist) the electrons are so few that they doubtless all lie in one ring, but there are reasons for believing that in atoms of higher atomic weight there are two or more rings. With a large number of electrons present—with the 100 electrons of the gold atom for instance—there may indeed be several configurations which will satisfy the conditions of stability. Even for comparatively light atoms Bohr³⁰ supposes that as many as five rings exist. Again from what part of the atom of a radioactive substance do these ejected α and β particles come? Soddy³¹ believes that both originate in the nucleus but that the chemical and the electrochemical properties are controlled by the outer ring of the electrons. Moseley regards the similarity of the X-ray spectra of different metals as satisfactory evidence that such radiation originates inside the atom, while light radiation is determined by the "structure of the surface." Rutherford³² and Bohr both raise the important question whether atomic nuclei contain electrons, and both conclude that they do. These and many other questions have already been asked but only

tentative and provisional answers have thus far been given. Doubtless there is a field here for much important experimental and theoretical work in the immediate future—a field which American physicists will seek to cultivate with their European brethren, who have done about all of the work thus far.

These hasty considerations perhaps suffice to show the varied character of the lines of evidence that have been developed during the past three years to give support to some form of nucleus atom. Radioactive phenomena, X-ray radiation and chemical properties seem to give united testimony for it. Doubtless the final type of atom has not yet been described for it is easy to criticize the views of Nicholson or Bohr or any other who has proposed a model, but it is probable that some form of nucleus atom will soon receive general recognition.

ALFRED D COLE

OHIO STATE UNIVERSITY

ADDRESS OF THE RETIRING VICE-PRESIDENT OF SECTION F OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

BEFORE proceeding to the special subject of this evening's address, which will be upon the research work of the Tortugas Laboratory of the Carnegie Institution of Washington, your retiring vice president begs permission briefly to plead the cause of the Zoological Section of the American Association for the Advancement of Science

Our grandfathers founded this association and during our fathers' day, in that

tense period wherein the foundations of established beliefs seemed crumbling into chaos before the onslaught of Darwinism, the Zoological Section of the association was a vital force in bringing order out of the confusion of doubt and fear that beset the America of the seventies

Then, in after years, there came the special societies, zoologists, anatomists, physiologists, ornithologists, entomologists and psychologists of America, and our Section F having lost its appeal to the investigator as a clearing house for his ideas, has sadly languished

However, let us not forget that the British Association which two generations ago was active in forming intelligent opinion in England, once also languished from a similar cause

Then to our British cousins there came the light of a great idea. The field of their association expanded to embrace the whole imperial realm. Great meetings were held in Canada, South Africa and Australia, and the colonies became intellectually one with the mother country in a sense never known before

The British Association is no longer a mere gathering of scientists, it is a mighty power in preserving that world wide sympathy with ideals of democracy and fair play upon which the very existence of Britain's vast empire must depend. For England's strength is neither in acres nor in gold, but in the hearts of her sons who toil at many a stubborn task in many a distant land

As servants of civilization, let the members of our own association meet the millions of America in a similar spirit

At these meetings, let us speak with rather than to our countrymen

Too often we may have looked upon the public as something colossal, crude and struggling, something far and apart from

our cloistered world within the college walls

Let us come among our fellows not as doctors gowned and coped, but as the simple men and women that we are, seeking advice and aid more often than we can impart knowledge or develop wisdom. Realizing as we do that could we but exchange the known for the unknown, the little that science has achieved would appear contemptible. From the frontiers of our culture we gaze into the vast unknown but it is but little that we can see.

Our science is not alone the concern of specialists but of every man and woman of our land and with the advent of modern medicine, antiseptic surgery and a knowledge of the law of heredity, great human problems have arisen.

We now stand as trustees guarding things of vast import for good or evil. The very word eugenics conjures up problems for the wisdom of humanity to solve. These problems of science have shaped themselves from out the mists of doubt and lie as awful things upon our path, yet the higher the precipices the safer the harbor they enclose and we await the wisdom of the wisest to guide us.

These are things too deep for the mere scientist, they are for each and every one of us, and the investigator is but one with the vast public in giving heed to their solution.

Yet in a deeper, more far reaching sense, our association has a mission humanity wide in its embrace, and as the duel has ceased to be respectable among individuals, so let war come to be regarded among the nations. It is with no boasting of virtue that we men of science of America can take this stand. We must speak as sinners pleading with sinners. Let us not forget that militarism has been in our own land as well as elsewhere. Let us remember that

every generation of Americans has drawn the sword, and that the most prolonged and devastating conflict of the nineteenth century was waged on our own soil over a question which Great Britain solved through a simple act of Parliament.

The light of civilization has glorified the summit of our ideal but the vast mountain below has forever remained dark in the barbarism of the savage. Our new born love of all humanity is superimposed upon ages of distrust, prejudice and hatred born of ignorance but let us recognize that the spark of kindness that seems so small to day is ours at least to foster until true to its destiny it shines as a blessing to all future generations of our earth.

To effect these things what better body can there be than the men of science of the nations of the earth acting in cooperation with that vast multitude of our fellows from whom we have received the blessed opportunity to labor and to serve.

The problems of our fathers' day were trivial compared with these. Let us therefore be true to the old ideals of our American Association and let it forever stand for *association* in terms of mutual helpfulness between our public and our men of science.¹

ALFRED G. MAYER

AID TO ASTRONOMICAL RESEARCH

THE experience of the Rumford, Elizabeth Thompson and certain other research funds shows that great returns may be obtained from relatively small grants to suitable persons. Owing to the excellent organizations resulting from the large sums given to astrophysics in this country, astronomers are well qualified to secure such results. Accordingly, the follow

¹Dr Mayer devoted the remainder of the evening to an account of the research work of the Tortugas Laboratory of the Carnegie Institution of Washington illustrated by colored lantern slides.

ing letter was sent, and the replies are given below in the order in which they were received

My Dear Sir The greatest return in astronomical output for a given expenditure, in my opinion, could be obtained by moderate grants to leading astronomers. I am accordingly sending copies of this letter to twelve of the American astronomers who would, it seems to me, make the best use of a grant of one thousand dollars a year for five years. I want to publish these needs and then see if the money can be obtained. Are you inclined to make me a statement of about one hundred words showing how you would apply such a grant? I give below my own statement as an example

Yours very truly,

EDWARD C. PICKERING

Statement

The New Draper Catalogue will fill eight quarto volumes of the Harvard Annals and will give the class of spectrum and magnitude of two hundred thousand stars, or more. Miss Cannon has nearly completed the observations, but publication could be greatly expedited by the employment of an additional assistant at an annual salary of five hundred dollars. Another extensive research on the photographic brightness of the stars by Miss Leavitt could be equally advanced in the same way. In carefully organized routine work a great increase in efficiency may be obtained by the use of such assistants.

Professor C. L. Doolittle desires \$500 to \$1,000 for publication of results already obtained.

Professor E. W. Brown approves of the determination of the position of the moon by photography as described below by Professor Russell, and suggests a determination of the lunar parallax by a similar method.

Professor F. Schlesinger states that a very efficient method for cataloguing stars by means of a photographic doublet has been developed at the Allegheny Observatory during the past few months. This is being applied to a zone four degrees wide at the celestial equator. We have been urged by astronomers here and abroad to extend this work to other parts of the sky. A grant of \$1,000 per annum continued for about twelve years would enable us to cover nearly the whole northern sky in

this way. Among other things, this work would help materially the progress of the great Astrophysical Catalogue, and would increase its value. If the same work were done by the earlier and ordinary methods it would cost not less than ten times as much and would be far less accurate.

Professor S. A. Mitchell states that the Leander McCormick Observatory has undertaken as its principal work the photographic determination of stellar parallax, an important research to which the 26 inch telescope is excellently adapted. The income of the observatory for the payment of all salaries (except the director's), for maintenance, and for improvements is less than \$1,500 per year. The award by Columbia University of the Adams Research Fellowship for the present year has made possible a much needed increase in staff. One thousand dollars per year would permit the continuation of parallax work, and would also allow expansion along visual lines and in photometric work.

Professor F. Slocum states that the Van Vleck Observatory will be finished during the summer of 1915. The principal instrument will be a new 184 inch Clark refractor. The mounting and clock work will be made by Warner and Swasey. The observatory is to be used by classes in astronomy of Wesleyan University but it is the intention of the director to devote as much time as possible to research. The chief feature of the proposed program will be systematic observations for the determination of stellar parallaxes. The midnight hours when parallax factors are small, will probably be used for micrometric or photometric observations. An assistant at \$1,000 per year to share in making the observations and to carry out the routine work of computation would greatly increase the efficiency of the observatory.

Professor F. B. Frost states that up to the end of 1913 5,100 stellar spectrograms had been obtained with the Bruce spectrograph of the Yerkes Observatory for the purpose of determining the velocity in the line of sight of northern stars, chiefly of spectral types B and A brighter than magnitude 5.5. Of

these spectrograms it has thus far been possible to measure only 2740, or 54 per cent., owing to a lack of assistance in this work. For 1910-13 the percentage measured is 48. With an additional \$1,000 per year for five years, additional assistants could be obtained so that these arrears of measurement could be made up and this program of work completed.

Professor H N Russell states that the photographic determination of the position of the moon at Princeton University Observatory, from plates taken at Harvard and measured here has given results probably more accurate than any previous method of observation. The provision of a salary of five hundred dollars a year for a computer will enable the continuation of this work which must otherwise be interrupted. An equal sum would provide a computer to work on eclipsing variable stars. Material for accurate light curves and elements of about one hundred of these systems as yet uninvestigated is contained in the Harvard photographs. The results regarding the density, surface brightness and other characteristics of the stars would be of great astrophysical importance.

Professor J A Miller states that the energies of the observing staff of Sproul Observatory are largely devoted to research and stellar parallax work. With such a grant as you propose at my disposal I should employ two assistants: one at \$500 per year to do the routine detailed work connected with a research of this sort, the second to aid in the measures and final reductions of the plates. I should have to pay the second assistant \$800 per year, the difference between the \$500 that you propose and the \$800 to be paid by the observatory. I could thus materially increase the quantity of our parallax output without in any way affecting its quality. In addition, this would enable us to utilize our present equipment (without any additions whatever), more nearly to its full capacity, by extending our work into closely allied fields."

Professor J Stebbins states that for the past few years the work of the University of Illinois Observatory has been the development

of an electrical method for the measurement of the light of stars. "As the work is quite new we must do a considerable amount of experimenting in the laboratory with the object of increasing the accuracy of observations at the telescope. These investigations are all carried on in addition to the regular instruction which must be done at a university observatory. We have some untrained student assistants but if we could get the services of a regular man and keep him year after year, our scientific output would be greatly improved and increased. It is very probable that after a certain time the university will be able to put such a research position upon a permanent basis."

Professor G C Comstock states that the Washburn Observatory is engaged in determining the positions of several thousand stars averaging about seventh magnitude to be utilized in an extension of Boss's Preliminary General Catalogue. Progress of this work is greatly hindered by entire absence of a computing staff. One or more computers are sorely needed. A grant of \$1,000 for a single year would be of value in this connection but such a grant continuing over five years would be much more than five times as useful since at the outset much time is necessarily given to training the computer to his work. His efficiency increases with experience.

Professor Philip Fox states that the most pressing need of the Dearborn Observatory is in the line of measurement of the many plates we have taken for the determination of stellar parallax and the reduction of these measures. The series of plates now has reached 948, and is being added to at the rate of about ten plates on every clear evening. Additional help for this work would greatly expedite its progress.

Professor W W Campbell states that the greatest return which the Lick Observatory can make for a small additional expenditure would come from the employment of a very capable observer to assist with the spectrographs attached to the thirty six inch refractor and to the Crossley reflector. The demands

upon such an observer are very severe because the apparatus is extensive and complicated and skilled and constant care must be devoted to the observations. Such services usually begin to be satisfactory about two months after the start is made, and their value increases through many years. The salary of such an assistant should be \$1000 for the first year and there should be an increase of \$100 each year until \$1500 is reached.

An unexpected result was that in nearly every case the principal need proved to be for assistants. Some preferred one experienced observer others two computers. In some cases it is believed that if the work were once started it would be continued by the university. An astronomer can often direct one or two assistants so that they will obtain as accurate results as if he devoted the same time to the work himself. A small appropriation may thus double the output of his observatory.

My own application is included since I believe that as important results can be obtained here as elsewhere but if all can not be provided for I recommend that other astronomers having fewer assistants should receive precedence. Even if only a portion of the sum asked for could be provided it is probable that an extraordinary relative output would be obtained. It is hoped that, in some cases those interested in a particular observatory may be willing to supply its needs.

EDWARD C. PICKERING

December 21, 1914

FRANCIS HUMPHREYS STORER

FRANCIS HUMPHREYS STORER, of the Massachusetts Institute of Technology and later of the Bussey Institution of Harvard University, was born March 27, 1832, and died July 30, 1914. His father was David Humphreys Storer (M.D., LL.D.) and his mother was Abby Jane (Brewer) Storer. He married Catherine A. Eliot, sister of Charles W. Eliot, June 21, 1871.

Professor Storer studied at the Lawrence Scientific School in 1850-51. He was assistant to Professor Cooke in 1853. He received

from Harvard University the degree of S.B. in 1855 and the honorary degree of A.M. in 1870. From 1855 to 1857 he studied abroad and from 1857 to 1865 he practised as a chemist.

The writer knew him intimately from 1865 to 1870 when he was professor of general and industrial chemistry in the Massachusetts Institute of Technology and the writer was his pupil. In that year he resigned his position to become professor of agricultural chemistry in the Bussey Institution, the next year he became dean of an office which he held until he withdrew in 1907.

Professor Storer's pupils say of him that he was the best of teachers of chemistry. He and Professor Eliot were the pioneers in introducing the experimental method of giving instruction to classes in chemistry and those who were ripe for it found in it the greatest inspiration. He was uniformly genial and had a great faculty of imparting his knowledge that was thoroughly interesting to his students. He possessed one of the most fascinating personalities of our day. Professor Rogers and Professor Storer were the two most inspiring teachers we had in the early days of Technology. Many of the pupils owe their absorbing interest in science to these two strong characters. In those days there were members of the faculty who were in favor of letting the students obtain the degree too easily, Storer was foremost in opposing this laxity, and insisted on the highest possible standard. He was a thorough teacher and a gentleman of high culture. He had a human side too which endeared him to his pupils. On one occasion when an expedition was arranged to visit the coal mine in Rhode Island all the party had arrived at the train and were excited and anxious because Eli Forbes had not turned up. At the last minute he appeared and stepped aboard as the train started and Storer remarked "and here is Eli the most prompt of us all."

All agree that his loss to Technology in 1870 was a severe one to that school.

Of his connection with the Bussey Institution it may be said he was always very ready

to help in any investigation that looked to the better condition of growing crops or of improving the land. He covered a wide range in those investigations and was sometimes criticized for matters that were not understood or seemed of small importance to ordinary interests. He was an excellent teacher and interested his pupils in the subject at hand sometimes pretty dry and did everything possible to give those matters a practical turn. His methods were clear and concise and he had little sympathy with slack work.

He was observant of current events and always spoke his mind freely in comment. He never "played to the galleries" but expressed his opinion of affairs as they appeared to him.

The Bussey Institution never had much money to carry on its work. Professor Storer was thus hampered by lack of funds and he was unfortunate in not having the faculty for getting help of this kind. He drew freely from his own funds which could not have been over large to help the school and the individual students.

In social intercourse he was never forward at all. His wife was a great help to him in this way and they together did many kind acts to a newly appointed instructor at the Bussey Institution. On her death he drew into himself more than ever and had little intercourse in an every day way with others.

Professor Storer's work is of the greatest importance in agricultural chemistry, in a way it is the foundation of modern agricultural chemistry. When he began, it was all new and he made the beginning.

ROBERT H. RICHARDS

BOSTON, MASS.

THE ANTWERP ZOOLOGICAL GARDEN

FROM the date of the bombardment of Antwerp, apprehension has been felt regarding the fate of the beautiful and costly zoological garden of that city. Messrs. Lorenz and Heinrich Hagenbeck, both of whom are yet in Hamburg, alive and well, have furnished the *Bulletin* of the Zoological Society of New York with a copy of a letter received by them from

Dr. Buttkofer, director of the Rotterdam Zoological Garden which reads as follows:

All the bears in the Antwerp Zoological Garden were shot prior to the bombardment. The large feline carnivora were put into strong transportation cages and removed to the rear of the garden, likewise prior to the bombardment, while the small felines were transferred to cages in the cellars of the Festival Building. A few days before the surrender of the city when the heavy cannonading started fires in all parts of the city which could no longer be put out in consequence of lack of water the large carnivora were likewise shot by resolution of the board of directors adopted contrary to the director's advice. None of the other animals were killed with the exception of a few venomous snakes. During the bombardment only one shell dropped into the garden striking the ground in the open space for the turtles where it fortunately did no material damage. Mr. L. Hoest and his two younger children were my guests from October 5 to the early part of November, while the other members of his family likewise came to Rotterdam towards the end of the bombardment. Mr. L. Hoest himself whose mind had suffered severely from the effects of the terrible excitement and of the successive events which overpowered him also came to Rotterdam for a few days after the bombardment.

By the earlier part of November all the members of the family had returned to Antwerp.

The garden and the animals kept there have suffered no further damage during the siege but you will readily understand that the number of visitors has so decreased as to be practically nil, while the membership will undoubtedly be reduced to such an extent that the very existence of the garden will apparently be put into serious jeopardy.

Everything here is in good shape, although there has likewise been a large decrease in our receipts which compels us to be exceedingly economical. I presume that similar conditions prevail in all the zoological gardens in Germany, as well as in your country.

BENJAMIN PIERCE INSTRUCTORSHIPS IN MATHEMATICS

THE Division of Mathematics in Harvard University announces that hereafter on or about the first day of March in each year it will recommend two persons for appointment to Benjamin Peirce Instructorships in accord-

ance with the following regulations recently adopted by the president and fellows of Harvard College provided suitable candidates make application (1) Appointments shall be made by the president and fellows on recommendation of the division of mathematics. Each appointment shall be for one academic year and shall carry a remuneration of not less than \$1 000 nor more than \$1 200 (2) A holder of an instructorship may be a candidate for reappointment but no person shall hold an instructorship for more than three years (3) Each instructor will be expected to teach two and one half elementary courses and one other course which would ordinarily be of an advanced character (4) Instructors will be permitted to attend without charge all courses of instruction under the faculty of arts and sciences and to enjoy the same library privileges as other instructors. They will be offered every facility towards the prosecution of original scholarly work the members of the division being ready to give all possible aid and encouragement (5) A candidate for an instructorship in any academic year must present his name to the chairman of the division on or before the first of February of the previous academic year. He should offer at the same time evidence of his capacity as a scholar and a teacher. For this purpose he should present such documents as (a) a dissertation accepted towards the fulfilment of the requirements for the degree of doctor of philosophy (b) published contributions to mathematical science (c) certificates as to his ability and success as a teacher (d) personal letters relating to his character and qualifications for the post.

In amplification of the above regulations it may be pointed out that these newly-established Benjamin Peirce Instructorships afford an unusual opportunity for young men of good training and ability at or near the beginning of their teaching career. The appointments are made on the basis of an open competition, Harvard has one of the best mathematical libraries in the country the amount of work required is very moderate (the course 'at Harvard being three fifty five minute periods

a week throughout the year) and includes opportunity for advanced teaching. This advanced instruction will be on subjects selected in consultation with the instructor and so far as possible in conformity with his wishes. By exception applications will be accepted in 1915 as late as February 15. For further information address Professor Maxime Bocher, chairman of the division of mathematics 48 Buckingham Street Cambridge Mass.

COMMERCIAL GEOGRAPHY AND WORLD POLITICS

DR ARTHUR DIX contributes to the *Geographische Zeitschrift* for June 11 an article with this title indicating a German point of view prior to the outbreak of the war. As summarized in the *Geographical Journal* he states that the tendency for inland communities to seek an outlet to the sea is becoming so marked that with rare exceptions such powers must now be regarded as in a state of unstable equilibrium. Such states in the general case must in his opinion either submit to be absorbed by the neighboring power which blocks the road to the sea or must forcibly seize a stretch of seaboard. He gives Asia as an example of a continent in which independent inland states have now practically ceased to exist. Africa as one in which they are gradually disappearing. The Transvaal and the Orange Free State are given as examples of countries which as soon as they acquired extensive relations with the world market fell as booty to a neighboring power. As examples of two inland states which must in the immediate future undergo political change he gives Abyssinia which he regards as being probably destined to fall into the hands of Britain and Serbia which must he thinks fight for her free access either to the Adriatic or the Aegean. Secondly great powers which have already one outlet to the sea tend to seek a double access. France has of course this double access already but the founding of the triple alliance, the recent history of the Russian Empire the opening of the Panama Canal some of the difficulties among the various powers in Africa the troubles in the Balkan

peninsula, are all discussed from the point of view of this search for an additional or an easier access to another sea. Thirdly, maritime powers, in his opinion, necessarily strive to extend their dominion over the coasts which face their own. Rome and Carthage, Italy looking across the narrow Adriatic and also across the Mediterranean to Tripoli, France and Algiers, the designs of Britain upon the coasts which encircle the Indian Ocean are all given as examples. Again he points out that when any power possesses a part of a navigable stream there is a tendency for it to seek to extend its dominion down to the mouth. Similarly a colonizing power which has taken possession of the mouth of a river tends also to follow that river up to its source. The same thing may tend to happen in civilized countries if the water of the river is used for irrigation or if stream control is necessary. Thus the control of the lower course of the Vistula by Prussia is difficult because its upper waters are extra Prussian. But the difficulty of the Polish question makes it necessary for Prussia to avoid covetousness in this connection, while a frontier adjustment which would deprive Prussia of the lower Vistula would cut off wholly German territory from the empire. The Rhine, he states is another case where purely political conditions stand in the way of a natural economic tendency. It is an advantage to Germany for the mouth of this river to remain in the hands of a neutral state so long as the neutrality of this state is effectively maintained for as it faces a powerful sea power, it would, if German be liable to blockade in war time. Again the fact that the Elbe and Danube are both Austrian as well as German rivers means that those two powers must either be allies or enemies and these rivers thus form part of the geographical justification of the triple alliance. On the other hand the relation of the great rivers of South America to the different states there suggests to the author that the political division of South America is in an unfinished condition and that great readjustment will probably take place there.

Finally Dr. Dix is of opinion that a spe-

cifically modern cause of political differences among nations lies in warring interests in the construction of great transcontinental railway routes. The permanent tension between Britain and Germany he ascribes, not to the causes usually given on either side, but to the great extra European railway schemes of the two powers. Germany, he says, is desirous of constructing and controlling an east to west line across the continent of Africa while Britain desires to complete the Cape to Cairo route, to which Germany is strongly opposed. Similarly he states that Britain is desirous of linking the Nile to the Indus by rail, and therefore opposes the completion of the Bagdad line to the Persian Gulf under German auspices. These causes of dissension might be got over by a mutual arrangement between the powers, or by a German-British alliance.

THE HUXLEY LECTURE

The Huxley lecture at Charing Cross Hospital was delivered by Sir Ronald Ross on November 2. From the report in the *British Medical Journal* we learn that before proceeding to the main subject of his address, which discussed recent advances in science and their bearing on medicine and surgery, with special reference to malaria and the transmission of diseases, he paid a well conceived tribute to Huxley who Sir Ronald Ross said, was not only the bulldog of Darwin, and the interpreter of Darwin's profundities to the world but also a patient and passionate investigator and a patient and dispassionate thinker regarding phenomena. But the lecturer continued Huxley was still more, he was a philosopher possessing all the very first qualities required for true philosophy. The clarity of his style was itself a guarantee of the genuineness and completeness of his thought. Secondly, his mind was fiercely critical in its search for truth, and he accepted nothing as fact which he himself had not endeavored to probe to the depths. Thirdly, no one has ever doubted that his aim was, not to astonish or to defeat or to persuade, so much as to reach the actual truth of every matter.

with which he dealt. He would have been delighted had he lived to recognize the bearing of recent advances in science on the medicine of the tropics. Sir Ronald Ross devoted the main part of his lecture to tracing the history of the modern application of parasitology to etiology and pathology dealing in particular with the growth of knowledge with regard to filaria, piroplasma and the malarial organisms. He sketched his own researches, the full history of which had been given in his Nobel lecture. It was only after several years' work that he recognized that the malarial infection was carried by a certain genus of mosquitoes only, not by *Culex* or *Stegomyia* but by the anophelines. He made the observation that the spores of the analogous malarial parasites of birds which he had already recognized in *Culex* entered the insect's salivary or poison glands. This led to the disclosure of the full truth, namely, that the parasites were not only taken from man by the mosquitoes as Manson had supposed, and not only put into man by the mosquitoes as King supposed, but that both hypotheses were true, the insects carrying the parasites directly from man to man. Summarizing the results obtained, he said that from the time of the Romans it was known that the malarial fevers were connected with marshes and stagnant water in warm countries. Later when it was seen that the disease was not confined to the proximity of marshes, the theorists conceived that there was a telluric poison which caused malaria and was especially abundant in damp places. All this was a very general proposition, and in order to prevent the disease it was necessary to undertake very extensive drainage. The new knowledge obtained rendered it possible to particularize the exact route of infection. It was now known that the poison was not spread uniformly in the air of warm countries but was always contained in the minute bodies of certain insects and more than that, in the still more minute salivary glands of these creatures. The discovery of the full life-cycle of the parasites made it possible not only to predicate the route of infection, but to determine exactly which species of mosquitoes were

concerned and to study the habits of the incriminated species. The genera *Culex* and *Stegomyia* which it was found did not carry the malarial parasite, breed most commonly in artificial collections of water around houses, the anophelines breed principally in natural collections of water such as marshes, puddles, streamlets and the edges of lakes, ponds and rivers. These observations showed the way to other inquiries which cleared up the epidemiology of yellow fever, sleeping sickness, tick fever, plague and might possibly throw light on that of dengue, Mediterranean fever and measles.

SCIENTIFIC NOTES AND NEWS

At the meeting of the American Society of Naturalists held on December 31, 1914, Professor Hugo DeVries and Professor Wilhelm Roux were elected to honorary membership.

SIGNOR GIULIELMO MARCONI has been appointed a member of the Italian senate by King Victor Emmanuel.

It is one of the privileges of the Spanish Academia de Medicina that it is entitled to a seat in the senate. The member of the academy recently elected senator in this way is Dr. B. G. Alvarez, one of the editors of the *Pediatría Española*.

DR. CHARLES R. VAN HISE, president of the University of Wisconsin, has been elected president of the Utilities Bureau established as an agency for municipalities in their dealings with public utility companies.

DR. RAYMOND PEARL of the Maine Agricultural Experiment Station has been elected a member of the editorial board of the *Journal of Experimental Zoology*.

THE American Institute of Mining Engineers, the American Electrochemical Society and the Mining and Metallurgical Society of America are giving a complimentary dinner on Friday, January 15, at the Hotel Plaza to Dr. Frederick Gardner Cottrell, in charge of the San Francisco laboratory of the Bureau of Mines, in recognition of his contributions to research. It is well known that Dr. Cottrell assigned the patents for his process of electro-

static precipitation of fumes to the research corporation the receipts from licenses to be used for the furtherance of research. As a result of this gift the research corporation is now in a flourishing condition.

The new officers of the Society of American Bacteriologists are as follows:

President D H Bergey University of Pennsylvania, Philadelphia Pa

Vice president John We nari Seattle Washington

Secretary Treasurer A Parker Hitchens Glen olden Pa

Council K F Kollerman W A Stocking R E B chanan and H J Conn

Delegate to the council of the A A A S M I Rosenau

The council of the society has decided to hold the next annual meeting in Urbana Illinois on December 28, 29 and 30 of December 1915. There will be a special meeting in the summer in San Francisco the date of which has not yet been fixed.

The Paleontological Society at its recent Philadelphia meeting elected officers as follows:

President E O Ulrich Washington D C

Vice presidents J C Merriam Berkeley Cal
Gilbert Van Ingen Princeton N J F H Knowlton Washington D C

Treasurer R S L H New Haven Conn

Secretary R S Baesler Washington D C

Editor C B Eastman New York

Dr E F BASHFORD has resigned the post of general superintendent of the Imperial Cancer Research Fund which he has held for the past eight years.

PROFESSOR W H KAVANAUGH head of the experimental department of the college of engineering of the University of Minnesota has been elected chairman of the Minnesota Section of the American Society of Mechanical Engineering.

F C DODG has been appointed assistant in animal nutrition in the Pennsylvania Institute of Animal Nutrition.

Dr E G LEARNER, Miss F M G Micklethwait and Dr E P Poulton have been elected to Beit Memorial Fellowships for Medical Research.

Dr J WALTER FEWKES ethnologist of the Bureau of American Ethnology left Washington on January 8 to take up his fieldwork in Arizona. Incidentally he will represent the Smithsonian Institution at the inaugural ceremonies of Rufus Bernhard von Kleinsmud as president of the University of Arizona. The exercises occur on January 11 and 12 at Tucson Arizona. At the conclusion of the ceremonies Dr Fewkes will continue his archeological work in that state and then proceed to New Mexico to conduct researches concerning the early inhabitants of the lower Mimbres Valley in connection with which the institution has recently published a report.

A SUCCESSFUL exploration tour through the wilds of Patagonia has been made by Dr L S Rowe of the University of Pennsylvania. Accompanied by the director of national territories and the governor of the Territory of Neuquen Dr Rowe traversed the southern section of the Argentine from the Atlantic to the Andes and from parallel 37 to parallel 42 south. Dr Rowe depicts in glowing colors the agricultural and industrial possibilities of this district at one time looked upon as a desert region.

A CABLEGRAM from Cairo Egypt has been received at the University of Pennsylvania announcing the arrival of Dr Clarence S Fisher leader of the university museum's Tackley B Cox Jr expedition to make further excavations in Egypt.

PROFESSOR M A ROSANOFF of the Mellon Institute and the Graduate School University of Pittsburgh lectured on January 4 and 5 before the New York University department of chemistry on the partial vapor pressures of mixtures in their bearings on the theory of solutions and the theory of distillation.

Dr G N STEWART of Western Reserve Medical School lectured before the Syracuse Chapter of Sigma Xi on December 15 taking as his subject 'The Physiologist in the Hospital and in the State'. Other speakers this semester have been Dr F P Knowlton, of the Syracuse Medical College who spoke on

November 10 on "Hunger and Allied Phenomena" and Professor Henry A. Peck, of the Liberal Arts College whose subject on November 17 was "Some Recent Aspects of the Nature and Extent of the Siderial Universe."

MR. CHARLES HALLOCK the veteran author and naturalist founder of *Forest and Stream* and the International Association for the Protection of Game is now living at the John Dickson Home in Washington. He is full of interesting reminiscences. He tells the story that he first met the late Dr. Elliott Coues at the Smithsonian Institution when Coues was seventeen years old and took him with him on an expedition to Labrador in 1860. They made large collections and placed 164 skins in the late E. D. Cope's museum at Philadelphia. Mr. Hallock would be glad to hear from any of his old friends.

At the annual meeting of the Mathematical Association January 9 the president Sir George Greenhill gave an address on mathematics in artillery science.

MR. HILARY BELLON gave the presidential address at the annual meeting of the Geographical Association held on January 7 at the University of London.

A MEETING in commemoration of the four hundredth birthday anniversary of Vesalius was held at the New York Academy of Medicine January 7 at which Dr. William H. Welch of the Johns Hopkins University delivered an address on 'Vesalius and the Spirit of the Time.' Dr. Fielding H. Garrison editor of the *Index Medicus* spoke on 'Anatomical Illustration Before and After Vesalius' and Dr. Harvey Cushing of the Harvard Medical School delivered a lecture on "The Portraits of Vesalius" illustrated by lantern slides.

PROFESSOR N. C. DUNER the distinguished Swedish astronomer secretary of the Swedish Royal Society of Science died on November 10, at the age of seventy-five years.

THE U. S. Civil Service Commission announced an examination on February 2, for engineer of mine safety investigations in the

Bureau of Mines Department of the Interior, at New York, N. Y. at a salary ranging from \$3,000 to \$3,600 a year. It also announced an examination for specialist in cotton testing in the Office of Markets and Rural Organization Department of Agriculture Washington D. C. at salaries ranging from \$1,800 to \$3,000 a year.

THE Rockefeller Institute for Medical Research will receive \$200,000 under the will of Henry Rutherford for cancer research work. This bequest was threatened by a contest of the will filed by a cousin of the testator but the contest was dismissed and the will admitted to probate.

A VIENNA medical journal as quoted in the *Journal of the American Medical Association* reports 844 cases of cholera with 331 deaths in Austria during the week ended November 7 including 90 cases in Vienna with 10 deaths. During the following week there were 78 cases in Vienna with 19 deaths.

THE international service of astronomical telegrams from Kiel having been interrupted by the war the management of the 'Zentralstelle' has been passed over to Professor Elis Stromgren Copenhagen Observatory.

THE Entomological Society of France has resumed the publication of its *Bulletin*. No. 15 of 1914 has just reached this country. At the meeting of October 14 the president M. Alluaud in addressing the society stated that in the absence of both of the secretaries at the front the publication of Nos. 13 and 14 had been delayed. He urged members still remaining in Paris not to interrupt the regular meetings under any pretext and to attend regularly. He quoted the speech made by Doctor Laboulbène at the meeting of January 11, 1871 during the siege of Paris in which the same course was urged. He further stated that a bomb had been dropped by an aeroplane very near the Museum of Natural History the day before the meeting. He stated that MM. Raymond Morgan and André Vuillet had fallen in battle. Vuillet was well known in this country on account of his publications relating to the gipsy moth and its parasites.

He was killed in an assault on September 10 at Ippecourt. Both of the secretaries Dr R Jeannel and Dr Maurice Royer were at the front but in good health.

We learn from *The Observatory* that it is proposed to recommence the publication of the *Gazette Astronomique* formerly issued by the Astronomical Society of Antwerp. The occupation of that town by the Germans occasioned the temporary suspension of the *Gazette*. A number of English astronomers on the initiative of Mrs Fiammetta Wilson of Bexley Heath have promised to aid by pecuniary assistance and literary contributions. It is intended to issue the *Gazette* monthly unless funds and the material for printing should justify publication at shorter intervals. The minimum subscription will be five shillings but those who are able and willing to aid more generously may subscribe half a guinea or a guinea as a more effective means of carrying out the idea of their Belgian comrades. The *Gazette* will be published in French and English and will be devoted to general astronomical subjects. It is hoped that the first number of the new issue will be ready early in January. Subscriptions and correspondence should be addressed to Felix de Roy hon sec 29 Stamford St London S E.

DR GEORGE D HUBBARD head of the department of geology at Oberlin College has issued a bulletin covering the work of the Oberlin Geological Survey during the summer. From June 25 to August 14 Dr Hubbard conducted a field survey in geology at Glen Lyn Virginia. The party consisted of Professor and Mrs Hubbard and nine students eight men and one woman. Three of the students were graduates seven were Oberlin men one came from the University of Cincinnati and one from Houghton Seminary New York. The work consisted of the making of a topographic map by means of transit and plane table and the making of a geologic map of about 40 square miles of hilly country partly in the folded strata of the Appalachians and partly in the dissected Allegheny plateau of nearly horizontal strata. A large collection of rocks and fossils was made

among the latter were several species of crinoids hitherto unknown in the Mississippian rocks of this locality. These collections are now being prepared and mounted for the Oberlin Geological Museum.

WITH a view to prolonging the original survey of the Palestine Exploration Fund to the Egyptian frontier and so connecting it with recent work of the Egyptian Survey Department a survey has been carried out under the auspices of the same fund by parties headed by Captain S F Newcombe RE. In a report written at Akaba in February of this year and printed in the July number of the *Quarterly Statement of the Fund* of which we learn from the *Scottish Geographical Journal* Captain Newcombe describes the general program of the survey and the progress of the work to date while a postscript written in June records the return of the party to this country after completing its labors. The area in question was but imperfectly known and the results are of some interest apart from their purely cartographical value. Five parties were engaged in the work and the map was made on the scale of 1:125,000 roughly contoured at 100 feet intervals. A triangulation was effected the fixed points of the Siani boundary determined by the Egyptian survey being carried further east while in the north a chain of triangles was carried across to connect with the original Palestine survey. In the south it was possible to save time and expense by observing large triangles the exterior points—Mount Hor and Jebel Tabā—being observed from two mutually visible fixed points over 40 miles apart on the Egyptian frontier and a framework thus supplied into which subsidiary points could be easily fitted. The main difficulties encountered were concerned with transport and the procuring of guides and supplies with a certain amount of hostility on the part of the Arabs but these were on the whole successfully overcome. A small area near Akaba had to be left unsurveyed owing to the unwillingness of the Turkish authorities to give the required permission. This was however mapped by Major Kitchener in 1883. The summit of Mount Hor

(where the size and bright coloring of "Aaron's tomb" were a distinct aid in the observation of rays over 55 miles in length) was fixed, relatively to the Siani survey, with a probable error of only 30 feet. The other results of the survey are mainly concerned with archeology, in the interests of which Messrs Woolley and Lawrence, archeologists connected with the British Museum, were attached to the expedition for part of the time. Special care was devoted to the accurate collection of names of localities, which were taken down, as pronounced by the guides, by an educated Syrian of the party. That of "Theigat el Amirin" thought by Professor Palmer to be possibly a relic of the Amorites, turned out to refer to a tribal fight of about 150 years ago between the Azazma and Amiri tribes. The Bedawin of this desert region seem to have moved there only within the last 500 years. All roads have been inserted in the new map, and a point of interest is the discovery that the direct route from Kadesh to Mount Hor is an easy road, though thought by earlier writers to be impossible.

THE *Royal Engineers' Journal* for May of this year contains, according to *The Geographical Journal*, an account by Captain C W Biggs, R E., of a recent somewhat serious encroachment of the sea at Fort Ricasoli, Malta, and of the measures taken to cope with it. The paper is illustrated by plans and photographs. The site of the encroachment is a line of weakness, due apparently to a fault in the rock structure, traversing the peninsula on which Fort Ricasoli is placed, on the north-east of the Grand Harbor. The trace of the bastion walls built by the knights of Malta about 1670, shows that even then the inlet on the line of fault existed. The winter storms have gradually eaten into the fault and burrowed a tunnel beneath the cliff, from which a sort of chimney was formed leading to the parade grounds above. Measures were therefore necessary to stop the encroachment, the proposal adopted being one for the creation of a breakwater across the mouth of the inlet by means of a number of concrete blocks chained together. The work has been con-

tinued for several successive years, the comparatively small blocks used at first proving inadequate to withstand the heavy seas. Some were washed out to the front, while others sank in the sand. The weight of the blocks was progressively increased until at last it reached fifty tons each, and this seems to have had a satisfactory result. Although some of the blocks have been shifted by the winter storms this has now taken place *inwards* while the sea has helped to defeat itself by piling up material behind the breakwater. All that is thought necessary for the future is the addition of more large blocks from time to time, and continued filling in behind them.

In the thirty fifth annual report of the United States Geological Survey, Mr Geo Otis Smith, the director, discusses particularly the province of the federal survey. An amendment which was offered in Congress to last year's appropriation bill would, if passed, have restricted the geologic work of the survey to the public lands. As the amendment failed the only result was to attract more attention to the basic investigative work of the survey, which embraces all the lands of the United States, the privately owned as well as the public lands. The examination of private property for private purposes is forbidden by the organic act of the survey, but the examination of private lands must be included in any general investigation. The determinative factor in the whole matter is whether the investigative work on privately owned lands yields results that are merely of local and personal interest or results that are of general and national value. Land ownership is only an incident when large questions of natural resources are considered. The special interest of the government in its own lands—the public lands—being granted, it must be added, as was suggested last year by Representative Sherley at a hearing before the House Appropriations Committee, that "So far as the development of the mineral resources of the country is concerned, it is just as important to know the resources of privately owned land as of government owned land." When it is remembered that in the First Annual Report

of the Geological Survey Director King prophesied for the United States a future annual output of mineral products having a value of a billion dollars and that the present production is two and one half times that amount it must be conceded that the desirability of the federal scientific investigations of these national resources is even greater than in 1880 'It is a most conservative statement Director Smith says that at no date has the general public been in closer touch with the United States Geological Survey or made larger use of the published or unpublished results of its surveys and investigations than at the present time

UNIVERSITY AND EDUCATIONAL NEWS

A BEQUEST of \$3 000 000 to Oberlin College by Charles M Hall the distinguished electrochemist and manufacturer of aluminum is announced The bequest is in the form of \$2 000 000 endowment to be used for any purpose \$500 000 to be used to build an auditorium \$100 000 for the auditorium's maintenance \$200 000 to be spent for campus improvements all property in Oberlin owned by Dr Hall and a valuable art collection

THE will of Miss Grace Hoadley Dodge for many years known for her educational and philanthropic activities in New York City contains bequests of \$1 400 000 for educational and charitable purposes as well as a number of deferred bequests of the same character The sum of \$500 000 is bequeathed to Teachers College Columbia University in the founding and conduct of which she took an active part The college will receive two deferred bequests one of which may be large To the National Board of the Y W C A the sum of \$500 000 is left and to the Y W C A of New York City \$200 000

At the meeting of the corporation of Harvard University on December 28 it was voted to establish a separate faculty for the Bussey Institution The vote was consented to by the board of overseers and the new body at present includes the following members W M Wheeler Ph D, W E Castle Ph D, R T

Fisher AB MF F M East Ph D C T Brues SM I W Bailey AB MF and C C Little SD of the Bussey Institution, G H Parker SD and W J V Osterhout Ph D of the faculty of arts and sciences and F E Tyzzer AM MD of the medical school

DR C E BURKE lately of the University of California has been appointed instructor in the department of chemistry at the University of Vermont

DR HOWARD D HASKINS formerly associate professor of biochemistry in the school of medicine of Western Reserve University has been appointed professor of biochemistry in the medical department of the University of Oregon

DR FREDERICK D HFIELD of Philadelphia has been appointed professor of plant pathology and pathologist Washington State College and Experiment Station Pullman Washington

DISCUSSION AND CORRESPONDENCE

BATESON'S ADDRESS MENILISM AND MUTATION

IN Bateson's thoughtful and stimulating address¹ a recognized authority on evolution attempts to summarize for us recent progress in the study of that subject by analytical methods It would be well for all engaged in some particular branch of this subject to attempt thus to lift the eyes from the scene of their individual labors and survey from time to time the citro ficil An indispensable sense of proportion and perspective is thus gained This is my excuse for commenting briefly on some of Bateson's fruitful ideas

That evolution occurs all biologists agree That the organisms now existing on this earth are different from those which formerly existed here no one questions But we are still ignorant of how they came to be different The geological record indicates that the change was gradual The supposed ancestors of the horse

¹ Bateson W Address of the President of the British Association for the Advancement of Science SCIENCE N S 40 pp 287-302 August 28 1914

for example, are less and less like modern horses the more remote in geological time are the deposits in which their bones are found. But students of evolution differ in their ideas as to how gradual the progress of evolution has been and is, for no one supposes the process ended.

Within my view stands the sloping bank of a reservoir which most visitors ascend by a flight of granite steps, but children often go up the grassy bank wherever they happen to encounter it. Either method takes one to the top the gradual or the stepwise mode of ascent.

Evolution was thought by Darwin to occur in two ways comparable with these the gradual and the stepwise. From Darwin's writings it would seem that he regarded the gradual as the more common and important method of evolutionary change among organisms, but it is clear that he recognized stepwise or 'sport' variation as of considerable value particularly in the production of new varieties under domestication.

But not many years after Darwin's death a question arose in the minds of certain thoughtful naturalists as to whether Darwin had rightly estimated the relative importance of these two methods of evolution. Galton, Bateson and DeVries have laid increasing emphasis on sport variations or "mutations" until these have come to be regarded by many as of overshadowing importance in evolution. The full fledged mutation theory² maintains that evolution occurs *by steps alone*, that is that new species arise from old ones by single discontinuous steps, never by gradual uninterrupted change. This theory has been the guiding principle in evolutionary study in recent years. Its basic idea is that natural species are invariably discontinuous and that intergrades between them do not occur except possibly as the result of sporadic hybridization,

such intermediate forms being unstable and so without significance. The attempt by Bateson³ to classify the variations which occur within species led him to the conclusion that only such variations as are discontinuous in nature can have species forming value since they alone are not "swamped by crossing." This idea has been supported by the observation that among species regularly dimorphic or polymorphic the several forms which remain distinct notwithstanding constant intercrossing, are Mendelian alternatives, conforming with the laws of dominance and segregation. Many of the striking variations in color and form which occur among domesticated animals and plants follow these same laws so that their rediscovery and verification in 1900 was rightly regarded as strong presumptive proof of discontinuity in evolution. At about the same time DeVries brought together in his book entitled *The Mutation Theory*⁴ a large amount of evidence favoring the idea of discontinuity in evolution most important of which was the repeatedly verified polymorphism of the seedlings produced by Lamarck's evening primrose.

Mendelian segregation however does not at present offer a sufficient explanation of mutation in the evening primroses so that provisionally we are forced to conclude with Gates⁵ that mutation and segregation following hybridization are probably distinct phenomena. It also remains doubtful whether the phenomena observed among evening primroses occur at all commonly among other plants or among animals. The so called "mutations" which Morgan has observed in the fly *Drosophila* are certainly not of this order, but are clearly due to Mendelian factorial variation. Many with Bateson think that Mendelism affords a basis for the explanation of all evolution and confidently expect the evening primroses sooner or later to be shown conformable with its fundamental ideas. In the

² The term "mutation theory" is here used in its widest sense, including not merely the ideas of De Vries concerning evolution among the evening primroses, but the general idea of discontinuity in the origin of species previously outlined by Galton and Bateson.

³ "Materials for the Study of Variation," 1894.

⁴ Gates, R. B. "Breeding Experiments which Show that Hybridization and Mutation are Independent Phenomena," *Zeitschrift für Vererbungslehre*, 11, pp. 209-270, 1914.

latest statement of his views, Bateson argues substantially as follows. Variations may be large or small. Those which are small are either not inherited or are of no consequence, being "slight differences that systematists would disregard." But large differences can not arise "by accumulation of small differences." Hence only large differences have evolutionary significance. In his own words:

We have done with the idea that Darwin came latterly to favor, that large differences can arise by accumulation of small differences. Such small differences are often mere ephemeral effects of conditions of life, and as such are not transmissible, but even small differences, when truly genetic, are factorial like the larger ones, and there is not the slightest reason for supposing that they are capable of summation.

Whether we may properly regard small differences as capable of "summation" depends upon what we mean by summation. Phillips and I² have shown that in the case of prebald rats the areas of white fur characterizing the race may be either increased or decreased at will and that the change takes place gradually, progressing steadily generation after generation and far transgressing the original limits of variation. The same is undoubtedly true of similar variegated patterns which mendelize among both animals and plants. Small differences which have arisen spontaneously have certainly been *aggregated* in this case. But crossing of the modified races shows that the aggregated changes have not been summated to such an extent that they constitute a single Mendelian factor, except in one case where it seems quite possible that something of this sort has occurred. I am by no means ready to regard summation out of the question, whether by that we mean mere aggregation or fusion into a new Mendelian unit.

Bateson has further expressed the view that evolution has occurred largely, if not exclusively, by loss of Mendelian factors resulting in striking variations that breed true from their first appearance and thus render the

parent species dimorphic or polymorphic. That many varieties of domesticated animals and cultivated plants have originated in this way will be admitted by any one who has studied them genetically. Darwin himself pointed out the importance of "sport" variation in producing new varieties of animals and plants under man's care and supervision and it is known that similar variations occur in wild species. But it is doubtful whether in a wild species a sport originating in this way has ever replaced the original form. Under domestication it is only the constant interposition of man that keeps the favored sports alive. Whether sport variation has had any part in the evolution of species is accordingly very doubtful. If we compare one wild species with another, we commonly find existing between them not single striking differences but numberless minute differences. Systematists usually name as diagnostic characters a few of the more striking differences, ignoring as they are quite warranted in doing all minor ones the enumeration of which is for their purpose superfluous. But if one makes an intensive study of related species he finds that they differ in endless details of structure and physiological behavior extending even to differences in size of the constituent cells of the body (Conklin) or of their parts (chromosomes, chromomeres etc). During recent years as the discrimination of species has become more keen, it has taken on more and more a quantitative expression. Series of specimens are measured and specific distinctions are based on absolute and relative dimensions of parts not on the 'presence or absence' of large striking features of organization. It is easy to dispose of the work of the systematist by assuming that he does not know his business but is it wise to do so? For other lines of evidence also indicate that the differences between species are quantitative and increase with genealogical divergence. This for example is the conclusion reached from such distinct methods of study as the examination of the forms of hemoglobin crystals in the blood of various species of animals and of the precipitin reaction of the blood.

¹ *L c*, p 285

² Publ No 195, Carnegie Institution of Washington, 1914

But quantitative differences such as distinguish species are precisely those which do not Mendelize in crosses Bateson says (p 291)

Of the descent of quantitative characters we still know practically nothing

By which he probably means that we know *nothing Mendelian*, since in this address he treats Mendelism as the all sufficient basis of evolution, and ignores a decade of intensive work in America directed toward the discovery of Mendelian factors as a basis for quantitative differences a work participated in by many different workers, all favorably disposed toward the idea but all unavailing For the uniform result of a cross which involves quantitative differences is the production of an intermediate which in turn produces intermediates only slightly more variable than the races originally crossed Dimorphism or sharply discontinuous polymorphism is regularly wanting after size crosses This is a fatal objection to the idea that specific differences are discontinuous in origin One who advocates this idea has no choice at present but to ignore (as Bateson does) all evidence derived from the experimental study of this subject

The idea that large differences can not arise by summation of small ones is rendered improbable by this evidence For if the larger (quantitative) differences can so readily be broken down into smaller ones it seems highly probable that the process is reversible Indeed the experience of breeders shows that it is The dog breeder alluded to by Bateson who titrated his colored fluids to illustrate blood dilution in crosses was, so far as quantitative characters are concerned, employing a very apt method notwithstanding Bateson's disapproval of it

Even sport variations, which truly Mendelize, and which form the basis of color varieties and other fancy varieties among animals and plants even these are capable of secondary break down or 'fractionation,' as Bateson admits In making this admission he differs from the supporters of the pure line theory who conceive that a Mendelian factor is incapable of change, but who apparently hold

the idea as an article of faith rather than one requiring proof

Secondary break down or modification of Mendelian factors is, however, coming to be so generally recognized that a special name is now applied to its products, that of multiple allelomorphs Even those who hold to the conception of "pure lines" now recognize that the same sport variation ("mutation" or 'locus') may assume several different conditions which viewed quantitatively form a graded series, but they insist on the *discontinuity* of the grades or forms which a Mendelizing character may assume maintaining on *a priori* grounds that these stages can not be bridged The perilousness of such a position is apparent from a single well known case The first discovered Mendelizing character in animals was albinism and it is one of the simplest and clearest cut of all Mendelian characters thus far discovered It was not to be expected that the single step between a wholly uncolored and the normally colored condition would be or could be bridged Yet two such intermediate stages have already been demonstrated which are unmistakable allelomorphs of albinism $\pm e$ which behave as alternative forms of the same genetic factor If two such intermediate stages may arise, why may not others arise, why not a dozen, why not a thousand? Is it safe to assume that this is not possible?

Bateson urges that in cases of color variation such as that of the sweet pea and the primrose the large changes came first and the smaller ones later by secondary break down or 'fractionation' The argument implies indeed he expressly claims, that large differences can not be built up from small ones I do not believe that either paleontology or the history of breeding will support Bateson in this claim On the former ground Osborn holds to a gradual origin of discontinuous differences between organisms A study of breeds of animals in comparison with their wild originals or present day representatives shows

↑ Osborn H F, "The Continuous Origin of Certain Unit characters as Observed by a Paleontologist," *Amer Nat*, 46, pp 185-278, 1912

that variation has not occurred merely by large losses subsequently fractionated so as to form intermediates. Not merely intermediates arise but also those which transcend any known original sports. Original black races have become blacker, original yellow races have become yellower, white-spotted races have become more spotted still at the will of the breeder. Large races also become larger, and small races smaller under the hands of the fancier. He does not limit himself to the production of intermediates.

To suggest further that all variation transcending limits previously existing is due to loss of inhibitors and so is really retrogressive is scarcely satisfying. It is a formal evasion of the difficulty but in no sense a solution of it. It belongs with the box within box idea of development. I agree with Bateson that variety formation within the higher animals and plants seems to be very frequently by a process of loss but I can not believe that this is the exclusive process concerned in the formation of new species or even of varieties. It needs but to carry the idea to its logical conclusion to show its absurdity. Is man merely an amoeba simplified by loss of inhibitors? I can not believe so. I can not believe that the original protoid molecule has since its original synthesis only grown simpler. New radicles have undoubtedly become attached to it as side chains replacing or supplementing old ones and changing its properties. The living substance is not merely *losing* constituents, it is also *gaining* new ones. Similarly organisms, morphologically and physiologically, change not merely by losses but also by gains. It is impossible to explain evolution satisfactorily by either process alone. The two go hand in hand and no doubt are constantly occurring among organisms. Change is universal. Mere subdivision of a species into two groups of individuals, which are prevented from intermingling, seems to be sufficient in time to make the two groups specifically distinct. Each keeps on changing in so many different ways that it would be little short of a miracle if both changed similarly and simultaneously in all respects. Direct en-

vironmental effects are insufficient to account for such organic changes, for among the best-known illustrations of divergent evolution are the animals of oceanic islands, close together and subjected to the same climatic agencies, undoubtedly descended from common ancestors at no remote period yet having become distinct probably through numerous spontaneous changes which isolation prevented from being ground down to a common level by inter-crossing.

These are commonplaces of evolutionary knowledge, familiar to everyone since Darwin and Wallace first called attention to them, yet we are in danger of overlooking them for the moment in our enthusiasm over a new method of attacking the obstinate problems of evolution. It may not be superfluous therefore to call renewed attention to them in this connection. Spontaneous variation is still with us and is as widespread as it was in Darwin's time. It is doubtful whether unvarying "completely homozygous" organisms occur anywhere outside the text books. In the case of organisms known to be varying genetically there is abundant evidence that small variations are heritable no less than large ones and we are by no means "done with the idea" that small variations are capable of summation.

With Bateson we must deplore the necessity of engaging merely in destructive criticism. It is indeed "a low kind of work." It would be so much easier, pleasanter and more satisfying to adopt a single explanatory principle for evolution and build on this. But it would be foolish to go on building lofty superstructures of hypothesis on an insecure foundation and the more carefully we scrutinize the mutation theory the more serious do our doubts become whether it is a secure foundation for evolutionists to build on. MASTODON TUSK IN GLACIAL GRAVELS

TO THE EDITOR OF SCIENCE. A tusk of a proboscidean, probably *Mastodon americanus*, was

found recently in a gravel pit in Pony Hollow twelve miles southwest of Ithaca N Y on the property of Mr Bert Drake Unlike most *Mastodon* finds from this region this is not postglacial It was found in place twenty four feet below the surface in stratified sand and gravel which was being used in good roads work The pit is in the base of an extensive terrace whose top follows the valley wall high above the outwash gravel plain which occupies the floor of the valley The exact origin of this Pleistocene terrace is obscure but it is certainly not later than the end of the ice occupation of the valley and may be earlier

The tusk was broken in removing the gravel Two pieces each about a foot long from ten to thirteen inches in circumference were presented to the Paleontological Museum of Cornell by E A Dahmen the road engineer Three approximate measurements of the curvature of the tusk gave from two feet one inch to two feet eleven inches as the radius of curvature

CORNELL UNIVERSITY

SCIENTIFIC BOOKS

THE TRANSLOCATION OF MATERIAL IN DYING LEAVES¹

THE fact of an autumnal transfer of nutrient matter from leaves was first clearly stated by Sachs in 1863 Sachs's statement was based on microscopical examinations of the leaves of a series of plants in various stages of their autumnal changes whereby he determined that starch and chlorophyll disappeared from leaves before their fall He extended this observation to cover most of the other nutrient materials in the leaf Swart however holds that the solution of this question in its broader sense is to be had only by chemical analyses such as he has made

According to Swart the first essential to a correct answer is a correct wording of the problem as follows

¹Swart Dr Nicolas Die Stoffwanderung in ablebenden Blättern pp 1-118 Taf 5 Jena Verlag von Gustav Fischer 1914

During the autumnal coloring of leaves can there be determined by chemical analysis a translocation of nutrient materials during the period extending from shortly before to directly after the close of the yellowing?

It is essential to draw the time limits thus sharply since this period represents a sharply limited externally recognizable terminal period in the life of the leaf which in addition to anatomical variations in the petiole may be directly recognized by the physiological processes which are indicated to us by the disappearance of the chlorophyll If we would answer the question as to whether before the fall of the leaf there may be demonstrated a transfer of any substances it is necessary to regard only the period during which the leaf as indicated by these externally recognizable processes prepares for its final act After answering this narrower question then we should consider the amount of these materials in the leaf at other periods of the year in order to arrive at a causal explanation of the phenomena

The necessary chemical analyses fall into two groups those which extend over the entire vegetative period of the leaves and those which cover only the period directly before and after yellowing In most of the former investigations the leaves analyzed began to be removed from the tree at a late period but quite independent of the exact time when the coloring began and ended The value of the results of such analyses must therefore be estimated with caution since even in most favorable cases they can only give us an answer to the question of whether in general yellow leaves are poorer in their content of any given substance than green leaves of any earlier period Thus a maximum or a minimum in the proportion of the given material in the intervening period would give results entirely misleading with reference to the question whose answer is sought

Another objection to former researches that extend over the entire vegetative period is that very frequently a large number of leaves for study were taken at one time from the same

tree By this act the metabolism of the remaining leaves is known to be altered Thus for example the rapidity of the translocation of carbohydrates from leaves is increased with the diminution of the number of leaves on the plant by partial defoliation transpiration from the remaining leaf surfaces is increased and this is accompanied by a more rapid depletion of starch The taking in of the nutrient salts is also favored by a diminution in the number of leaves

If dead leaves are used in the analysis another source of error is introduced since substances may be washed out of dead leaves exposed to the weather In former researches a yellow color has been held to indicate death and all yellow leaves accordingly designated as dead Swart discusses these and other sources of error in all researches on the subject prior to Wehmer's *Kritik* of 1892 He argues with Wehmer that all results published before his paper can be relied upon to only a limited extent but he disagrees (p 37) with Wehmer's view that these results argue against the validity of the theory of a depletion before leaf fall for he knows of no case where the failure of a translocation has been demonstrated beyond doubt

In his own researches Swart employed the method devised by Stahl of cutting out with a die (or a cork borer) portions of the leaves for analysis thus avoiding the troublesome and inaccurate measuring of the area of an entire leaf Tabular statements of the results of several analyses are given on pages 59 to 67 the material including leaves of *Anthurium* sp *Liriodendron Tulipifera* *Ginkgo biloba* *Laserpitium latifolium* *Parothis pernica* *Aschylus Hippocastanum* *Salix caprea* *Sorbus intermedia* *Quercus* sp and others These analyses show that the leaves in the brief period preceding their fall and during their coloring had suffered a loss of nitrogen phosphoric acid and potassium, and these losses especially in the case of nitrogen and phosphoric acid were quite considerable These results confirm *in toto* those of former investigators The slight loss of magnesium in individual cases may in the opinion of the author

be attributed to variations in the analyses, in consequence of the inequality of the research material Iron remains rather constant

It is worthy of note that calcium silica, phosphoric acid and chlorine materials which at other times become richer in leaves increase only a little or not at all From this it may be inferred that in general in the last vital period of leaves only slight additional quantities of nutrient salts are taken in from the soil On the other hand the two analyses of *Laserpitium* (as shown in the table page 67) in so far as they are comparable indicate that the composition of leaves may vary considerably in different years

No general law or principle can be formulated from the known behavior of nitrogen phosphoric acid and calcium Such an inference must be based on a study of all the investigations bearing on the subject The fact that the literature contains certain contradictions as to the behavior of calcium serves only to indicate (in so far as the researches have been carried out with sufficient care) that the behavior of any given substance is not uniform, but varies within wide limits according to the plant and the external conditions

In consideration of the rather considerable losses especially of nitrogen and phosphoric acid suffered by the leaves studied by Swart he finds himself in entire agreement with the view for which Ramann and Stahl contend, namely that the loss of substances suffered by leaves before their fall is wholly restricted to their period of yellowing Microscopic investigations of yellowed leaves (pages 70-96) also substantiate this conclusion

The second chapter is devoted to The Coloring of Leaves Having demonstrated that the translocation of nutrient materials resulting in a permanent loss of these substances from the leaves takes place in the relatively short period of a few weeks duration marked externally by the loss of chlorophyll the author now turns his attention to this period in order to ascertain how far a study of the yellowing of leaves would lead to the same conclusions as did the chemical analyses

The period of yellowing or of coloring in

general, in which are completed those processes which are associated with the degeneration of the leaves varies in length (according to the species of plant) from a few days to several months. In unusually dry, or in wet cold years (e. g., 1911 and 1913 in Germany) this period began several weeks earlier than normally, and was of briefer duration. Under these conditions the loss of substance which leaves suffer through autumnal translocation is notably less than under normal conditions especially when an early night frost brings the life of the leaf to an abrupt end.

That the vascular bundles exert an influence upon the process of change of color is evidenced by the fact that the change always begins in those parts of the parenchyma that are farthest from the veins and spreads thence by degrees first to the smaller veins then to the main veins reaching the petiole last of all. As the yellow color spreads the stomata (as Stahl has shown) quite generally become closed.

Swart then asks what has become of the chlorophyll where the yellow color has appeared and notes that this question can not be considered to advantage except in the light of the newer conceptions concerning the nature of chlorophyll. Then follows a review of the chlorophyll studies of Sorby, Tswett, Willstätter, Kohl, Czapek and others. According to Kohl (1902), there belong to the yellow pigments of chlorophyll, carotin and two xanthophylls α and β . Tswett (1903) distinguished in addition to carotin, three xanthophylls α , α_1 , β . From subsequent researches of Willstätter we have become better acquainted with two of these yellow accompaniments of chlorophyll. One is an unsaturated carbohydrate of the composition $C_{40}H_{56}$, identical with the carotin of carrots. The second, the xanthophyll of older authors is an oxide of carotin, with the formula $C_{40}H_{54}O_2$. Both pigments are crystallizable. According to Willstätter, both these yellow pigments play no rôle in photosynthesis, but are concerned in respiration, and with this view Swart agrees.

Returning now to the question as to the behavior of these green and yellow pigments,

during the yellowing of the leaves, Swart rejects the hypothesis that the green ones disappear from the leaves, while the yellow ones, as such, remain behind. As to whether the chlorophyll is merely translocated as such, or whether it first undergoes a decomposition, there is no *a priori* reason for considering the first alternative as correct, while at the same time no instance is known where the colorless rhizomes of our perennial plants become green in winter. Observations of the bark of girdled branches above the girdling as compared with the bark below the girdling, also give negative results, and so on this ground also we may reject the hypothesis of a translocation of chlorophyll as such.

If, however, the chlorophyll suffers a disintegration, then either the disintegration products are removed from the leaf or else they remain where formed. Stahl (1909) showed that the former is the case and demonstrated that the separation of a leaf from the stem or portion out of the leaf blade, caused a marked retardation of the yellowing in the leaf or isolated portion. The same result was obtained on trees in the open in the case of leaves at the commencement of color change by separating a part of the blade from direct connection with the vascular bundles, by a cut or simply by pinching. Swart has repeated these experiments with the same results as those obtained by Stahl. For their firmer establishment there is needed only the application of the law of mass action. Swart therefore concludes, with Stahl, that the chlorophyll passes from the leaves into the stem in the form of its disintegration products.

The question of the fate of the yellow coloring matters is next considered. Kohl held that the yellow pigment that remains behind in yellowed leaves consists of carotin and also of the xanthophylls, α and β found by him in green leaves but that the yellow pigment of the normal green chloroplasts remains unaltered during the autumnal color changes. In direct opposition to this Tswett, by means of his adsorption method, found that, in most cases, the larger part of the yellow pigments in yellowed leaves represents a new formation,

which he provisionally designated as autumn xanthophyll. The question as to whether it is simple or complex Tswett did not solve. If Tswett's idea is correct then it is highly probable that we have to do here with a derivative of the normal yellow pigment of the leaf—possibly with a further oxidation product of carotin. Swart refers to the contrast (first noted by Stahl) in the behavior of the yellow and green pigments and the biological significance of yellowing and etiolation showing how the yellow pigments containing the elements C, H, and O remain in the leaf while the green pigments which contain also N and Mg (two elements whose retention by the plant is more important than that of the other three) are transplanted back into the plant before the death of the leaves.

Here is a lack of agreement with the results of the chemical analyses which show that the magnesium is not removed from yellowing leaves and a satisfactory explanation of this contradiction in favor of the results above recorded is not at hand. One may consider that the magnesium contained in chlorophyll represents only a very small part of the entire amount of that element which is present in leaves so that considering the variations which the results of the analyses always show the translocation of this small part may be often not noticeable in the end result. Unless we abandon the idea of a translocation of the chlorophyll in the form of its disintegration products we must establish the fact that the magnesium very probably takes no part in this movement.

Swart then gives attention to the changes in the cell contents of the yellowing leaves disclosed by a microscopical examination. Four different processes (to which Sachs first called attention) are studied: (1) The destruction of the outer form of the chlorophyll grains; (2) the disintegration of the green pigment; (3) the translocation of the chlorophyll substance; (4) the translocation of the starch. These processes which may occur in any order or simultaneously are studied and described. Contrary to Mer, Swart believes that the oil, formed by the disintegration of the chloro-

phyll remains in the leaf at the time of leaf fall. Wide variations are noted in the behavior of the starch. In some leaves which have just begun to turn yellow very little starch was found while in others quite yellow the yellow portions were found to be full of starch. Swart confirms the observations of Mer as to the sequence of steps in the disappearance of the starch namely first from the parenchyma cells of the leaf blade then from the veins of the blade and finally from the vascular bundles of the petiole. Small traces of starch remain with the intact chloroplasts in the guard cells of the stomata. It is not strange that traces of starch remain in completely yellowed leaves, when we recall that the solution of starch is greatly inhibited by the very low temperatures which often occur suddenly in autumn and that there is also a high content of insoluble carbohydrate as shown by chemical analysis.

As to the behavior of the plasma itself Swart failed to confirm the observation of Kienitz Gerloff that only disorganized remnants of plasma are to be found in yellowed leaves. The mesophyll cells give the impression of being very poor in plasma in comparison to the parenchyma of the vascular bundles but the plasma utricle and the nucleus remain intact. The cells of the leaf even after leaf fall are by no means dead. That a translocation of nitrogenous substance occurs (as the chemical analyses conclusively demonstrated), was also determined by the microscopical study. This may be associated with a destruction of the plasma and a transfer of the disintegration products but Swart could find no evidence of a translocation of the plasma itself as held by Kienitz Gerloff.

In 1860 von Mohl showed the untenableness of Schacht's view that the death and fall of the leaf was caused by the formation of the abscission layer of periderm at the leaf base for in many plants this layer does not form and in the cases where it is present the vascular bundles are not interfered with by its formation. Observations to the same effect by Tison were confirmed by Swart who considers that there is no longer any doubt that the forma-

tion of the abscission layer does not interfere with the translocation of materials between stem and leaf although, as Tison demonstrated, thyloses may form in the vessels, and callus in the sieve tubes, but other observed changes (lignification, cork formation and stoppage by wound gum) take place only after the leaf has fallen.

To test Tison's statements as to the formation of thyloses and callus, Swart employed indigo carmine, a stain that does not penetrate the protoplast, and is not poisonous (like eosin) in concentrated solution. Branches containing leaves that had begun to turn yellow as well as green leaves were placed in deep blue solutions in light, and the penetration of the stain followed by observing cross sections. In all cases within a few hours or longer (varying according to the species or the length of the branch) the stain had advanced into the vascular bundles of the petiole, and even into the veins of the blades of the yellowed leaves. The stain appeared earlier in the green than in the yellow ones although the green ones were farther away and this may be explained by the stoppage of the stomata above described. In how far the closing of the stomata or the changes in the leaf base are to be considered as the primary cause of the diminished suction in the yellow leaves was not determined. The fact remains that any considerable stoppage of the path of liquids is not the rule. The observation that completely yellowed leaves often remain for many days in their exposed places on the tree without becoming dry leads us to the same conclusion. The author also finds that the leptome elements of the vascular bundles are not cut off by the abscission layer, so that the transportation of substances from the leaf is not hindered in that manner. These facts meet all objections to the transportation theory based on the argument that the abscission layer, being formed before yellowing begins, prevents the passage of materials to and from the leaf.

We are accustomed in our thoughts always to associate leaf fall with a degenerative

change of color, but that leaves out of account the periodic or the continual leaf fall outside of temperate regions, and even often in autumnal leaf fall, where we observe, especially on certain trees, that many leaves fall when still green, or only half colored. On more careful investigation, however, these latter cases are found to be due to some unfavorable external conditions such, for example, as frost, which may cause a rupture of the leaf by the formation, at night, in the abscission layer of ice crystals which thaw on the following day. Other causes mentioned are storms, sudden increase of turgor in the active zone, disease of the roots or of the leaves themselves and the leaving of collected plants for too long a time in the collecting case. Thus it is seen that plants shed their leaves, not alone when they have ceased their function as organs of nutrition but also when the life of the plant is threatened especially as a result of too great transpirational activity.

Mention is made of such trees as the beech, hornbeam and oak many or most of whose leaves remain on during the winter on account of their failure to form the abscission layer until the following spring.

The red pigment of the anthocyan group, occurring in solution in the cell sap, and to which the autumn landscape owes its special charm is also formed at other seasons. Its appearance before the death of the leaf is restricted to a relatively small number of species and then it does not replace the yellow pigment but only masks the latter. It often occurs in mature leaves when there is no outward indication of initial degeneration such as the disintegration of chlorophyll. An active assimilation, combined with a migration of carbohydrates induced by nocturnal cold, is a *conditio sine qua non* for the accumulation of sugar in the cell sap, which in turn, is the antecedent condition for the formation of the red pigment. Thus it is that we have the most beautiful red colors in autumn when cold nights alternate with warm days.

There follows a brief discussion of Piek's theory that the presence of anthocyan in leaves

favors the digestion of starch and the translocation of carbohydrates and especially that it increases the activity of the starch digesting enzyme. Wortmann disagreed with this but Stahl in his researches with variegated leaves found a satisfactory explanation of the favorable influence of the red pigment on the process of the translocation of materials. The formation of red pigment in leaves in spring and fall and in high mountains in summer is associated with low temperatures which retard the translocation of the photosynthate and thus decrease the activity of photosynthesis. Stahl's thermoelectric investigations with red spotted leaves demonstrated an increased absorption of heat in those parts of the leaves containing anthocyan. On the basis of these results Stahl modified Pickett's thesis as follows:

In the heat absorbing red coloring matter of leaves the plant possesses a medium for accelerating the transformation of matter and energy.

Contrary to the light shield theory which holds that the anthocyan is a protection against the destructive effect of a too intensive light on the chlorophyll, Stahl's theory especially in view of the favoring of the process of translocation has the advantage of either giving biological significance to the red pigment in autumn leaves or of pointing the way to investigations of the metabolism in autumn red leaves.

It remains to be proved whether the favorable influence of the red pigment on the translocation of material may actually be demonstrated by comparative chemical analyses or in other words whether and in how far red leaves under the same conditions suffer a more thorough emptying out than do other leaves on the same plant which have not formed the red pigment. Swartz's analyses of green, yellow and red leaves of *Parrotia persica* with reference to nitrogenous contents showed that before leaf fall the red leaves are more thoroughly emptied than the yellow ones.

If a leaf is dropped from the branch shortly after its color has turned (be the color either yellow, red or white) the cells still remain alive, except in a few cases where *pari passu*

with the loss of chlorophyll a brown pigment spreads over the leaf surface. The outer appearance and also the microscopical characters indicate that the cells by no means contain merely disorganized matter but maintain their complete vital functions until the appearance of the brown and black color which indicates the death of the leaf. Thus with Tswett Swart concludes that the color change of leaves is not a postmortem decomposition but a physiological process and that we have to distinguish two phases in the change of color, viz., the *necrobiotic* with its yellow red and white tints and the postmortem characterized by the appearance of brown and black color.

But Swart holds that the theory of translocation does not stand and fall with the question as to whether the leaf during yellowing becomes dead or not for as he has shown in the investigations here recorded the translocation of material still takes place from the portions of leaves that have already entered upon change in color. Nevertheless Swart adds the theory in consideration of certain cases must suffer a certain limitation.

A chapter on final considerations (pp. 97-117) concludes the book.

C. STUART GAGER

SPECIAL ARTICLES

ON THE ORIGIN OF THE LOESS OF SOUTHWESTERN INDIANA¹

The gallant defenders of the grand old aqueous theory of loess deposition seem to be retreating southward though their rear guard vigorously contests every district yielded. Just now they seem to be crossing the Ohio River. Rumor has it that a strip on the north side of the river in southwestern Ohio is still being claimed southwestern Indians² has been in their undisputed possession for 10 years, and the latest publications on the geology of western Kentucky and southeastern Missouri contain such words as "the writer may state his

¹ Published by permission of the Director of the United States Geological Survey.

² *Bull. Geol. Soc. Am.* Vol. 14, pp. 152-176 and the Patoka folio U. S. Geol. Survey.

belief that the loess of the region under consideration is of fluvial and not of eolian origin,"* and "the submergence during the deposition of the loess."

However, changing the figure, there is reason for suspecting that some have secret longings for a geological statute of limitations which would remove responsibility for statements expressed a few years ago.

Fortunately for the sake of long and interesting debate, it seems impossible to say the last word on the origin of the loess. Nevertheless, some, perhaps weary of the controversy, or perhaps for novelty, have seemed ready to compromise and admit that some loess may have had one origin and some another. Such an interpretation was placed on the loess of southwestern Indiana in the reports just referred to, and the principal object of the present communication is to suggest that another view concerning this material may be tenable.⁵ The suggestion is perhaps somewhat tardy, but it has received several years of careful consideration.

The correct interpretation of loess like that of other geologic phenomena depends much on the study of extensive areas. The writer's first hand knowledge of the loess comes from most of the area of its occurrence in the United States from Nebraska to Ohio, and from Minnesota to Louisiana and also from a part of that in Europe but it has been particularly in the survey of the Quaternary geology and physiography of a dozen quadrangles in southern Illinois that he has been impressed with the idea that the conclusions set forth with regard to the loess of the Patoka quadrangle are not widely applicable. Naturally, the attempt was made to correlate the work in Illinois with that done in nearby districts,

* Water Supply paper No 164 U S Geol Survey, p 46

⁴ "The Physiographic Development of the Low lands of Southeast Missouri," p 30

⁵ The loess is not the only superficial material of the Patoka quadrangle concerning which the writer is inclined to a different view from that set forth in the folio, but it is perhaps the most important

and for this purpose the Patoka area has been visited a half dozen times in as many different years. The object of the later visits was to review the work done in previous years and to make sure that none of the critical places had been missed, though a complete survey was not undertaken.

Some quotations from the Patoka folio will indicate the view there set forth.

Previous to the present survey of the region no attempt had been made to differentiate the silts, but evidence is now at hand for separating them into two types (1) thick, yellowish, calcareous, and frequently stratified silts along the immediate borders of the Wabash Valley, which are designated *marl loess*, and (2) the more clayey, oxidized and structureless silts designated as *common loess*, forming the general mantle over the surface more remote from the river. The first is believed to be of aqueous and the second of eolian derivation.

The marl loess

occurs at all altitudes from the flood plain to the 500 foot level (120 feet above the river), at which altitude it frequently forms broad terraces and flats burying a rugged rock or till topography. The thickness of the marl loess in these terraces and flats is sometimes 40 feet or more but thicknesses of 10 to 200 feet are more common.

The marl loess is characterized by a high calcareous content and frequently by a sandy texture. Calcareous concretions are exceedingly abundant. In many instances it is delicately stratified and in some cases is interbedded with sands or fine gravels or even carries scattering pebbles itself.

The perfection of their stratification, their interbedding with sand and gravel the presence of pebbles in them, their terraced form, and their limitations to the borders of the Wabash point to water as the most probable agent in the accumulation of the marl loess deposits, the deposition probably being in a fluviolacustrine body occupying the lower Wabash Valley, into which the silt was brought from the Iowan ice sheet by the Wabash River.

The view expressed in the *Bulletin of the Geological Society of America*, however, seems to be that the "marl loess" is partly eolian and the "common loess" partly aqueous. To the present writer it does not appear likely that any of the loess of southwestern Indiana

is water deposited or has any stratification except in certain places where it has a very obscure banding roughly parallel to the present surface such as loess commonly displays

However, some of the material included under the head of "marl loess" has a very distinct and approximately horizontal stratification. Most such material is sand of fairly uniform grain but layers and lenses of gravelly sand, calcareous sand, and also clay and silt are common. The lime is especially abundant in the lower ends of tributary valleys. But so far as the writer could find this material is not present at a greater altitude than 440 feet or about fifty feet above the flood plain and it appears to him to be a part of a widely developed system of valley fillings, remnants of which he has traced through nine states in the upper Mississippi Basin. The tops of the remnants are generally 40-60 feet above the present flood plains. The valley fillings seem to have grown as units notwithstanding the fact that some streams are greatly overloaded and others not at all. It thus happened that some tributaries were ponded by the filling in the main valleys into which they discharged and the deposits laid down in such comparatively quiet water are fine grained and calcareous the lime being largely in the form of small irregular masses differing somewhat from loess kindeken and possibly secreted by plants.

Whatever the origin of the stratified material surely it is not correct to call it loess, for it differs markedly in several respects from the material known by that name elsewhere, particularly at the type locality in Germany. The principal respects are that it is heterogeneous being made up of material of all degrees of fineness from clay to gravel whereas loess is very homogeneous, (2) that it is co-extensive with the valley fillings above referred to. Thus the "good sections of a very siliceous form of the marl loess in the bluffs at Mt Carmel" the writer would call good exposures of waterlaid terrace sand, having no relation whatever to the true loess.

It seems, further, that some wind-blown sand has been included in the "marl-loess." The

valley filling along the Wabash has been the source of much dune sand. Most of the dunes are near the valley bottom, but some of the sand has been carried up on the valley side and some even to the top of the bluff and neighboring divides. This seems to have happened in at least two different epochs, and there appear to have been two or more epochs of loess accumulation though one is most important. As a result the sand and loess finger into each other in places but in no section are there more than 2 or 3 layers of each.

It therefore seems to the writer that the "marl loess" includes

- 1 Ordinary bluff loess (the principal part)
- 2 Glacial outwash
- 3 Deposits laid down in ponded tributaries
- 4 Wind blown sand

The stratified and sandy material of classes 2, 3 and 4 are markedly different from true loess.

The division of the loess of the Patoka quadrangle into marl loess and common loess appears to have a relation to the fact that on the bluffs near very large streams loess is generally coarser (or at least more free from extremely fine particles) and thicker and more calcareous than at a distance of several miles. The greater part of the material mapped as marl loess seems to be loess of the ordinary bluff phase. That is to say, it is buff colored, soft, massive unstratified homogeneous, calcareous earth. The particles are mostly angular quartz grains too small to be classed as sand but some of them are clay. It commonly contains shells of air breathing animals and is characterized further by a tendency to develop and retain vertical cliffs.

The fact that both the bluff loess and the clay loess are best developed on the east side of the valley seems more reasonably accounted for by the prevailing westerly winds than by postulating that "the main current hugged the western shore" especially since throughout the Mississippi Basin the loess is more extensive on the east side of the few main streams than on the west.

The writer confesses an inability to see the "terrace form of the marl-loess" as described, the top being said to have a position 500 feet

above sea. As mapped, it lies at all altitudes between 380 and 500, and there are somewhat flattish areas at all altitudes but especially at 440-450 the altitude of the top of the valley filling in this region. Since divides generally have a rounded profile, and those of this area stand about 500 feet above sea probably more of the surface here is near that altitude than any other but the fact is scarcely evident from the topographic maps.

Also the loess does not seem to the writer to show a marked change in character at the 500 foot contour. In color texture and other physical and chemical characters including those brought out by mechanical analyses acid tests and the microscope the material seems to be a single deposit. In a very rough way the altitude of the surface increases with distance from the river and for this reason the highest "marl loess" may be on the whole a little more like the clayey phase ordinarily found at some distance from larger streams than the average bluff loess but the difference is slight and there seems to be no noticeable change at the 500 contour.

The statement that the range of fossils is coextensive with that of the marl loess none being found above the 500 foot level" is not in accord with the writer's observations. One rather large collection was made at an altitude of 555 feet two miles north of the center of Patoka and another at 525, one fourth of a mile northwest of that point. Another collection was made two miles north and one and one half miles west of Owensville at an altitude of 535 feet. At the first named locality the following species all of which are land shells were collected *Pyramidula alternata* Say *Succinea* sp. (young), *Helicodiscus multilineatus* Say, *Euconulus trochiformis* Montague, *Polygyra monodon* Rock *P. hirsuta* Say *Pupa muscorum* L. *Helicina occulta* Say.

The maximum thickness of the "marl loess" is only about 40 feet and yet it is continuous except where it has been subjected to severe erosion as on the steeper valley sides. If the "marl loess" were water deposited—a valley filling now dissected—one might reasonably expect to find remnants of triangular

cross section and limited extent located where the meandering streams had chanced to leave them instead of an almost continuous layer covering valley sides. The marl loess as mapped has a vertical range of 120 feet or more but the maximum thickness is scarcely a third as much. Like true loess it appears to mantle hill and valley alike in places obliterating minor irregularities, but nowhere greatly modifying the major features.

The writer found no pebbles in place in the material which he would class as loess, and none in any of the material described as marl loess at a greater altitude than 440 or at most 450 feet. Pebbles are to be sure pretty good evidence that a deposit is not eolian providing they are certainly in place. But there are so many ways in which pebbles are scattered that unless they were certainly in place or very nearly in place it would seem unsafe to regard them as evidence of water deposition.

The relation of the true loess to the general form of the surface of southern Illinois throws a rather important sidelight on the problem. The Mississippi and Ohio are bordered by high rough country and the general surface slope is not toward these two principal streams but away from them. The loess, however here as elsewhere is thick porous calcareous and fossiliferous on the high hills near the rivers and gradually becomes thin and clayey toward the low country at some distance from them. If the part below 500 feet were water deposited thousands of square miles of the interior lowland must have been submerged and this area should presumably have a considerable deposit if not a thicker one than the higher country but the deposit is thin or wanting in the lowland. It thickens gradually toward the rivers and is thickest on the hills where the water must have been most shallow along the Ohio and Mississippi. The bluff loess certainly appears to be a single deposit from the bases of the hills at 375 or 400 feet to their crests at 700 or 800 feet where it is thickest. The distribution of the loess is very different from that of material known to be waterlaid valley filling.

Briefly, the writer believes that the so called

marl loess of southwestern Indiana consists of wind deposited true loess, stream laid valley filling, and dune sand, and that the true loess part of it together with the "common loess" corresponds to the well known loess of other parts of the Mississippi basin

ELGENF WESLEY SHAW

SOCIETIES AND ACADEMIES

ST LOUIS ACADEMY OF SCIENCES

At a meeting of the Academy of Sciences of St. Louis, held October 19, Professor Nipher gave an account of his work during the summer of 1914, at his summer place in Hessel, Mich., on "Magnetic Disturbances in the Earth's Field due to Dynamite Explosions, Burning Black Powder and the Fog horn of a Steamer"

The magnetic needle was mounted on a frame of timber the vertical posts of which were set two feet into the ground. The frame and the boxes containing the control magnets were loaded with half a ton of rocks. The boxes containing the control magnets were also clamped to the frame with large wooden clamps. The base of the airtight vessel containing the magnetic needle was also clamped to the frame. The torsion head was braced by means of wooden bars. Four cords at right angles to each other were attached to the torsion head. They passed outward and downward through holes in the table, and upon them were hung two bars of wood at right angles to each other. These bars were also loaded with rock. The apparatus was protected from heat effects by a series of blankets within the tent, having air spaces between.

No difficulty was found in producing marked local disturbances in the earth's field by means of dynamite suspended in air to the east and to the north of the tent. The needle being at right angles to the magnetic meridian, this disturbance indicated a variation in the horizontal intensity.

The amount of dynamite exploded varied from half a stick six or eight feet from the tent, to thirty sticks distant 275 feet. In the larger explosions, the sticks were placed end to end on bars of wood having a cross section $1 \times 1\frac{1}{4}$ inch. Each stick of dynamite was securely held in place upon the bar by means of a winding of heavy cord. The ends of the bar suffered no appreciable injury. Those parts in contact with the dynamite vanished in dust so fine that it was difficult to find any trace of it. The changes in the position of the needle in

explosions of this character amounted to ten or fifteen minutes of arc.

Much more marked effects were produced by distributing half a stick of dynamite into a column about 15 feet in length. It was packed closely into the angle of a little trough of wood, which rested upon a heavy beam of wood. The trough was held in position by means of masses of rock hung on cords. The column of dynamite was in line with the needle and either above or below the level of the needle. In this way deflections of about one degree of arc were produced. The direction of deflection was reversed by reversing the direction in which the explosion traversed the column. The end of the column nearest the needle was distant from it about ten feet.

This seems to indicate that a magnetic field is created around this exploding column like that which exists around a wire conductor carrying a current of electricity. In most of the experiments of this character only a small part of the column exploded. It is believed that the conditions which will cause an explosion of the entire column with equal violence throughout have been finally attained, and this work will be continued.

The black powder was spread over a platform having an area of 25 square feet placed a few feet from the west side of the tent. The amount of powder spread over the platform was from 25 to 50 pounds. The flame shot upward to a height of 15 to 30 feet. The lines of the earth's field were deflected around the region filled by this flame. The intensity of field within the tent was momentarily increased. The deflection of the needle amounted to from 25 to 50 minutes of arc.

At the request of Professor Nipher, the captains of the steamers of the Arnold Transit Co. were instructed by the president, Mr. Geo. T. Arnold, to blow a loud and prolonged blast on their fog horns when at the nearest point to the observing station. This distance was about half a mile. Appreciable effects were thus produced when the air was quiet, the sky was clear and the intensity of the field had reached a high value. The result in every case was to decrease the intensity of the earth's field.

In two cases the blast from the 5 o'clock boat was at once followed by a premature appearance of the sunset disturbance. Rhythmical vibrations over from 10 to 20 degrees of arc at once followed, and continued for four or five minutes. This result needs further examination under more favorable conditions.

DURING the first years in the life of the American Association for the Advancement of Science it was customary for the members to meet in much broader groups than they now do. As the membership grew and as the number of papers increased it became necessary to divide the association into smaller and smaller groups. Section A as we now know it was organized in 1882. It was a happy circumstance that the plan adopted in that year did not separate the astronomer from the mathematician. For a time this section played a very important part in the history of American science: the meetings were well attended and both the mathematician and the astronomer contributed numerous and weighty papers. In more recent years our section has lost something of its former influence. The establishment about twenty five years ago of what is now the American Mathematical Society did much to draw away the interest of mathematicians, and even of astronomers for in the records of that society we find a goodly number of purely astronomical papers and two of the earliest presidents were astronomers. Fifteen years ago what is now the American Astronomical Society was formed and this has still further increased the separation between the two sciences. It seems a great pity that the two should so seldom find themselves together in the same room. The astronomer, in common with the physicist, the chemist and

¹ Address of the vice president and chairman of Section A Astronomy and Mathematics American Association for the Advancement of Science, Philadelphia December 1914

others greatly needs the help that the mathematician can give. On the other hand, I believe that the mathematician has something to learn from the astronomer with regard to the point of view from which he pursues his researches. The difference in this respect between the two is becoming greater and greater. In choosing a subject for an address this afternoon I thought it best to take advantage of one of the rare opportunities that an astronomer as such gains audience with the mathematicians and to dwell upon this difference of view point with the hope of aiding in bringing together those who have meat and can not eat, and those who would eat but want it. Any such attempt however ineffective by itself and however feeble in itself, is well worth while.

This difference in view point is nothing more than a recurrence of the struggle that occurs in every kind of human activity between the essentials of a subject and the technique of that subject. It is a remarkable fact that the outcome of this struggle is not always in favor of the former, but that mere technique is sometimes able to gain permanent mastery and to submerge completely the objects for which it was created. The best illustration of this is to be found in the painter's art. We know that there was a time when painting was regarded as a mode of expression through which lessons might be taught and learned or through which at least the world might be amused. But for many a long day painters have refused to take this view of their art. They hold in frank contempt a picture that tells a story, and their standards of what constitutes a great picture are unintelligible to any one who is not himself a painter. You will remember the picture by Whistler, at the Metropolitan Museum of Art in New York, called "A Woman in White." Although executed in

oils, it is wholly in black and white. We are told that it was painted to show that certain effects could be produced in oils without the use of color. Here then is a painting that artists deem a great one, although to the general public it has no subject at all and conveys next to nothing. The majority of modern paintings belong to the same class and it has gotten to be well understood that artists are to paint only for other artists. In any definition of a great painting skill and technique are indispensable, but a man is at once called a Philistine if he asks that artists use their talents for some other purpose than merely to record and exhibit personal achievement.

Painting and poetry are arts that in their essentials are much the same; their chief difference being one of tools. But while the painter has glorified his tools more and more the poet has kept his head and has not forgotten what tools are for. I suppose it would be possible to construct a poem without using any other vowels than *o* and *u*. If so we should have the literary counterpart of Whistler's "Woman in White." Of course such an effort would not be regarded seriously for a moment, nor should we tolerate in literature any mere exhibition of technique. Yet technique is quite as indispensable here as in painting and great facility is as rare in the one art as in the other.

Astronomy and mathematics have their technique and are having their struggle with it. A century ago Gauss, a great mathematician and a great astronomer, speaking for his times as much as for himself announced as his motto, "*Pauca sed matura*," and adopted as his crest a tree laden with fruit, few in number but remarkable for their perfection. Such sentiments as these and the feeling that lay behind them have undoubtedly done more to hinder the progress of science than to ad-

vance it. If there is any question as to what Gauss meant we have only to turn to his biography to find the answer. He did not care to touch in print any subject that he felt he could not exhaust merely to contribute to it seemed to him like plucking unripe fruit. Thus his published work extensive though it is represents only a part and it may be only a small part of the unremitting labor of this wonderfully fertile brain. We know for example that Gauss had developed the principles of the method of least squares while he was still in his teens but it was not until fourteen years later that he ventured into print on this subject. He would doubtless have wished to delay even longer had not Legendre in the meantime unearthed and published the same principles. We can make a good guess at the reasons for Gauss's delay. The method of least squares is founded upon an assumption which can be put in various forms but which always remains an assumption. Gauss would doubtless have wished to prove this assumption from fundamental principles or at least to have given it a more axiomatic dress but this neither he nor any one that has come after him has succeeded in doing. An even better illustration of the former attitude of men of science in the matter of their obligations to science is afforded by Gauss's part in the history of non-Euclidean geometry. In a letter to a friend he states that he had occupied himself extensively with Euclid's axiom concerning parallels and goes on to outline very briefly some of the results he had obtained. This letter contains all that is known of these researches. A few years after it was written Lobatchewski published the little book in which he proves that the parallel axiom is no axiom at all but a pure assumption and shows that another kind of geometry is imaginable in

which the opposite assumption is made. In view of this work it would have been necessary for Gauss to revise what he had already done before publishing it. He preferred however to suppress it altogether and when after his death his scientific effects were overhauled no trace of this subject was found among his papers.

It will be understood that it is not Gauss that I am presuming to criticize but rather the times in which he lived. That was an age when it was taken for granted that a man should think of his scientific reputation as coming first and when the form in which he gave his researches to the world was considered as important as their content. In more recent times the man of science has taken a new view of his calling and of his duties and it is largely because of this new policy that progress has been so rapid in some directions. In astronomy for example the great strides that have been made in the present generation can be attributed to two things: first there is the unprecedented concentration of effort. Great telescopes have been erected and great observatories have been built for the purpose of solving single problems or a single group of closely related problems. If these problems should remain unsolved in our time the work will be carried forward by a succeeding generation and perhaps completed many years after those who initiated it have passed away. Cooperation is another powerful implement that time has placed in the hands of the astronomer more precious to him than any telescope or any observatory can be. Thanks to it no pressing problem appears at present above our horizon that is too great for him to attack. If you will examine the working programs of our astronomical institutions you will find that much the greater half of what they are doing is being carried out with direct ref-

ence to the needs and the activities of other institutions. Cooperation often makes severe demands upon the individual, it means that he must be willing to use his mental and his material equipment in furthering an impersonal plan, it means that he must sometimes subordinate his own judgment to that of others, it means that he must sometimes use methods that he would like to modify in some particular if he were working alone.

I believe that it is true that the astronomer has broken more completely with ancient tradition than has the mathematician. Many of the latter are still inclined to take what may be called the artistic view of their work, they refuse to admit that mathematics is a means to some other end, and they frankly assert (half in jest and half in earnest) that their science need have no reference to material things. A few years ago a prominent mathematician, speaking I think from the very chair that I am vacating to-day, quoted with sympathy the sentiment that mathematics is born and nourished out of the play in the mind of mankind. It is difficult for me to see the difference between this view and the view that a chess player takes of his game. In the one we may start if we like with a set of axioms and an arbitrary set of postulates without inquiring whether they apply to the world around us, and we may then amuse ourselves by tracing the consequences. The chess player does this very thing: he sets out with a set of axioms that he calls *rules*, and a set of postulates that he calls *openings*, and after the expenditure of much thought and ingenuity he is able to trace the consequences.

It is understood I hope, that I have been speaking in averages. By no means all astronomers have gotten rid of the artistic notion in their work, and by no means all

mathematicians have severed their connection with the real world by applying the square root of minus unity. But there is no denying that the idea of cooperation in a broad sense has not yet taken a strong hold in mathematics. Whether as great advantage would flow from cooperation between one mathematician and another, as is the case in astronomy, it is not for me to say. But when we come to speak of cooperation between mathematics and the other sciences the benefits that would follow are difficult to overestimate. Let me spend a few minutes in pointing out how greatly the help of the mathematician is needed in a single astronomical subject, namely, that which concerns spectroscopic binaries. If in these remarks I emphasize individual stars, Algol for example, you will understand that these are types of a large class and that the problems they present are of cosmical importance.

The first star to be recognized as variable in its light was probably Algol. The Arabs seem to have made this discovery, for it is difficult to account otherwise for the very apt name they gave the star, Algol or El Ghoul, the changing spirit or demon. The same discovery was independently made by others, among them Goodricke of England in 1782, when he was eighteen years of age. Goodricke continued to observe the star until he had determined the period and the nature of the light changes and he advanced what we now know to be the true explanation of its changing light, namely that Algol is periodically eclipsed by a darker companion of nearly the same size as itself. This conjecture was a very bold one in that day, for we must remember that binary stars were then unknown. A great many double stars had been detected, but it was supposed that these were the result of perspective and chance. It was about this

time that Michell showed that on the doctrine of probabilities double stars were too numerous to be fortuitous groupings in all cases, so that binary stars were in a sense discovered by a mathematician and not by an astronomer. Twenty years later Herschel proved at the telescope that some double stars are real binaries, and that they revolve around each other by reason of their mutual attractions.

In 1880 Pickering showed that Algol's changes in light conform well with the eclipse explanation, and he suggested that the matter might be settled by the spectroscope. He argued that the orbital velocity of Algol due to the attraction of the dark companion should be considerable, and should change its sign according as the observations are made before or after the time of minimum light. The spectroscope was not quite ready at that time to handle problems of such delicacy, but a few years later Vogel succeeded in greatly increasing its accuracy for the determinations of velocities by substituting the photographic plate for the human eye. Algol was among the first stars to be tested by Vogel, and his observations indicate precisely such velocities as the eclipse explanation implies. This explanation has been accepted without reserve since that time, and has been extended to all the numerous variables of the same kind that have in the mean time been discovered.

It was early noticed by Argelander and others that the period of Algol, the time between two successive light minima, is not constant. Attempts were made to represent these inequalities by formulae involving the second and higher powers of the time, but the star refused to conform to such equations. In 1888 Chandler examined this question with great thoroughness, he showed that by the introduction of *periodic* terms all the observations up

to that time could be well represented. The most important of these terms has a coefficient of 173 minutes and a period between 130 and 140 years. To account for this Chandler supposed that the system contains a third body, and that Algol and its eclipsing companion revolve around the common center of gravity of all three bodies in this long period. The dimensions of this orbit were supposed to be such that the light equation in it for an observer on the earth would be 173 minutes, and thus the eclipses would be advanced or delayed by this amount, according as they occur on the nearer or the farther side of this vast orbit. Chandler was quick to see that this explanation entails irregularities in the proper motion of Algol, and that these might be large enough to be unearthed from meridian observations. An examination of all the material of this kind then available convinced him that such an effect is really present, the coefficient of the oscillation coming out $1''.3$, and its period 131 years. This result was apparently confirmed in a general way by Searle at Harvard Observatory, making use of additional observations secured for this express purpose. Baushinger, however, after applying to the catalogue positions the best available systematic corrections, concludes that there is no evidence whatever of a periodic term in Algol's proper motion. In the following year, Boss overhauled the same observations once more and decided that the probabilities were in favor of the presence of a term with a period of 131 years, but with a coefficient much smaller than that found by Chandler, 0.5 against $1''.3$. In later years Boss seems to have changed his mind as to the reality of this term, for in his Preliminary General Catalogue, published in 1910, he treats Algol as though its motion were uniform, although in the

case of other stars in this catalogue he devotes much attention to periodic inequalities.

It should be remarked that the absence of an appreciable periodic term in the proper motion does not necessarily imply the non existence of Chandler's third body, since his theory does not demand any particular coefficient for this periodic term. The only condition is that that coefficient must be at least twenty times the star's annual parallax and thus an accurate determination of the latter quantity would throw some light upon the present question. Unfortunately no determination of the parallax accurate enough for this purpose has as yet been made.

Starting with Chandler's inequality of 173 minutes Tisserand has attempted an explanation that does not assume the presence of a third body. He shows that if Algol be slightly flattened and if the orbit of the eclipsing satellite be somewhat elliptical, the orbit itself will revolve slowly and uniformly in the same direction as the orbital motion of the satellite. Consequently the eclipses will occur earlier than the average time if the periastron point is in the half of the orbit that precedes eclipse, and later than the average if the periastron point is in the half that follows eclipse. This explanation is beautifully simple, and for a time seemed to be the key to the puzzle. I am able to say, not without some regret, that Tisserand's explanation is no longer tenable. In his memoir the following relation is established:

Period \times eccentricity = 3 1416 \times the inequality. In this case the period is 2 87 days, and the inequality found by Chandler is 173 minutes, an eccentricity of 0.13 is therefore demanded, but this is out of the question. A long series of spectrographic observations made at the Allegheny Observatory shows conclusively that

the eccentricity of this orbit can not possibly be as great as 0.13, that it is more likely than not to be under one fifth this amount, and that therefore no inequality greater than forty minutes can be plausibly accounted for in this way.

Shortly after Chandler's formula for the inequality was published, the star (always El Ghouli) thereafter began departing from it little by little, until now the eclipses occur more than an hour later than the formula implies. The character of the inequality is once more in doubt, but as the existence of some kind of inequality is beyond question, this does not lessen the necessity for an explanation.

While the chances in favor of the reality of Chandler's third body have been growing less and less, evidence has been steadily accumulating in favor of an entirely different third body in this system. Since the publication in 1890 of Vogel's classic observations, it has been well known that the radial velocity of Algol is affected by an oscillation whose semi-amplitude is about forty kilometers and whose period is the same as that of the light changes, 2.87 days. In 1906 Belopolsky of Pulkova detected the presence of another oscillation in the radial velocity, the amplitude being much smaller than the other, and the period several hundred times as long. Observations made at the Allegheny Observatory have confirmed this discovery in an unmistakable way. The period of this new oscillation is found to be a little less than two years. It could be explained by the presence of a third body of such mass and so situated that the projected distance from Algol to the center of gravity of all three bodies is about two thirds of the distance from the earth to the sun. It is natural to inquire whether other explanations are not possible, or, in other words, whether the shifts in the spectrum lines from which this third body is inferred

may not arise from other causes than changes in velocity. This disturbing question is one that frequently recurs to the mind of the astronomer. Happily, in this case it can be answered in the negative without hesitation. The presence of the third body necessitates a light equation similar to that imagined by Chandler, but now of course with a period of less than two years and with a small amplitude. This amplitude can be computed in advance, we find that it amounts to about five minutes of time. I have examined the rich photometric material on this star accumulated in the second half of the nineteenth century and have found that this light equation is actually present. This seems to leave no doubt that the shift in the spectrum lines is nothing other than an effect of velocity and that the system of Algol contains at least three bodies, only one of which is visible in even our most powerful telescopes.

It is at this point that the man at the telescope must turn to the mathematician and ask him whether this third body can in any way produce the long inequality in Algol's period, that is, in the time that elapses between successive eclipses. If this should be found not to be the case, what dynamical explanations are possible other than those already tested and rejected?

The answer to these questions would doubtless apply to other eclipsing variables, for many of these show similar inequalities in their periods, though as yet in only one other case has the presence of a third body been demonstrated.

A somewhat similar problem is presented by the so called secondary oscillations that have been announced for certain spectroscopic binaries. If we observe the velocities in a system as carefully as we can, we may draw a curve that expresses the rela-

tion between time and velocity. Curves of this sort from various stars will differ widely from each other, but all must conform to certain restrictions, which are in fact those that follow from Kepler's laws. Now for the majority of binaries this is found to be the case, and by assuming that the orbit of the body we have observed has certain dimensions, shape and situation, the velocity curve can be represented within the limits that the accuracy of the observations leads us to expect. But this is not always so: a number of spectroscopic binaries were found for which the velocity curve did not conform to simple elliptic motion. It was then assumed that the system must contain a third body whose attraction causes perturbations in the place and in the velocity of the bright component that we observe. By adopting suitable mass and distance for this body it was found possible to represent the velocity curve fairly well. Too much emphasis should not be placed upon such a representation, however, the assumption of a third body is very much like the adoption of additional pairs of Fourier terms in an empirical formula, and it would have to be a velocity curve of very complex form that did not resemble, within plausible limits, one of the great variety of curves that so many terms would yield.

It has developed recently that many of the cases in which secondary oscillations were apparently present could be explained as a systematic error of observation. This is caused by the presence on the plates of the spectrum of the fainter component which sometimes blends with that of the brighter in such a way as to distort the measures. Leaving out of account all the stars whose secondary oscillations can be explained in this way, we find that practically all the remaining cases are also variable in their light, but

not in such a way as to permit the eclipse explanation to apply. This circumstance causes the observer once more to inquire whether the shifts in the spectrum lines that he observes are always velocity effects, or at any rate whether they are due to orbital motion. These remaining cases have another peculiarity, the period of the secondary oscillation is always found to be either just one half or just one third of that of the principal oscillation. If we interpret this in terms of a third body we have a system in which the three components are close together and revolve around each other in simply commensurate periods. It is for the mathematician to say whether such a system can be stable, and therefore whether such a third body is possible. Although this is a problem of many years' standing it has not yet been approached from the mathematical side, so far as I am aware. It seems probable to the speaker that such a system will be found to be unstable for reasons similar to those that account for the dark divisions in Saturn's rings and for the gaps in the distances of asteroids from the sun, these divisions and gaps corresponding to places where the periods would be simply commensurate to that of one of Saturn's satellites in the one case, and to that of Jupiter in the other. It is worthy of remark that in not a single instance where a third body has been inferred from a commensurate secondary oscillation, has this body been confirmed by a subsequent detection of its spectrum or otherwise. It is true that in Lambda Tauri two oscillations, both of short period, have been detected, but these periods seem to bear no relation to each other.

A mathematical problem connected with binaries, more important than either of the above, has to do with the origin of these systems. This is one of the few prob-

lems in sidereal astronomy with which the mathematician has concerned himself to any great extent, but it is still far from being in a satisfactory state. The past history of the moon, in a dynamical sense, formed the subject of an exceedingly laborious investigation by George Darwin more than thirty years ago. He concluded that the earth and the moon had once formed a single body and that they had broken away from each other by a kind of fission induced by the rotation of the body on its axis. Tidal friction is now set up, it causes the two bodies to draw away from each other, the month to become longer and the orbit of the moon to become somewhat eccentric. Darwin and others have extended this reasoning to double stars, and here the recent work on spectroscopic binaries seemed to afford a striking confirmation of the theory. It has been found that close binaries almost invariably have circular orbits and that their physical condition, as revealed by their spectra, is of the sort that is generally accepted as indicating youth. Widely separated binaries, on the other hand are apt to have eccentric orbits and to show signs of old age. Still more recently the mathematical side of the question has been reviewed by Moulton, Jeans, Russell and others. It now appears that Darwin's results are at least incomplete and that the causes he adduces are not sufficient to account for the genesis of the moon or for that of double stars. The chief difficulty is that tidal friction is not competent to drive apart to any great distance two bodies of comparable mass that have separated by fission. It appears probable in this view that the separation must have occurred long before the bodies formed stars, that is, while they were still nebulae. The difficulties of reconciling certain observational facts with this view are

great but it would be out of place to recount them here

We see that binary systems offer a rich field for the labors of the mathematician. Other subjects in astronomy are equally inviting and I have no doubt that other sciences have as much to offer. An eminent psychologist for example has said that the time has come for a great mathematician to concern himself with psychological problems. There is a proverb to the effect that to him that is well shod the whole earth is covered with leather. And so the mathematician may walk where he pleases. What particular path he chooses is not a matter of great importance but it is important that he be abroad and doing and that he do not sit at home admiring his shoes.

Science has often been likened to a warfare and such a simile as this naturally recurs to the mind at this time. We may think of science as at first occupying a small domain surrounded by the vast territories of the unknown. In the early days it was easier than now to add to this domain. A single bold spirit starting out in almost any direction could often wrest much from the adversary. But as the domain of science increases so also do the extent and diversity of its boundaries. The more obvious points of vantage are already taken and the character of the warfare must change. The day of guerilla warfare is gone it is now necessary to act in larger groups and for each man to be willing to serve at the side of others. This policy often requires the suppression of personal ambition and deeds of individual heroism become less frequent but great victories are to be won in either kind of warfare only if the soldier is imbued with such a spirit as this:

FRANK SCHLESINGER

ALLEGHENY OBSERVATORY OF THE
UNIVERSITY OF PITTSBURGH

THE PLACE OF FORESTRY AMONG NATURAL SCIENCES¹

In an old forest magazine *Sylvan* is a story about Germany's great poet Karl von Schiller. Schiller taking rest at Illmenau Thuringen met by chance a forester who was preparing a plan of management for the Illmenau forest. A map of the forest was spread out on which the cuttings for the next 220 years were projected and noted with their year number. By its side lay the plan of an ideal coniferous forest which was to have materialized in the year 2050. Attentively and quietly the poet contemplated the telling means of forest organization and especially the plans for far distant years. He quickly realized after a short explanation the object of the work and gave vent to his astonishment.

I had considered you foresters a very common people who did little else than cut down trees and kill game but you are far from that. You work unknown unrecompensed free from the tyranny of egotism and the fruit of your quiet work ripens for a late posterity. Hero and poet attain vain glory. I would like to be a forester.

An opinion not unlike that held by Schiller before meeting with the forester still commonly prevails in scientific circles in this country. It is quite generally believed that foresters are pure empiricists something on the order of gardeners who plant trees or range riders who fight for est fires or lumbermen who cruise timber carry on logging operations or manufacture lumber and other forest products that for whatever little knowledge of a scientific character the forester may need in his work he depends on experts in other branches of science on the botanists for the taxonomy of the trees on physicians chemists and engineers for the proper understanding of the physical chemical

¹ Paper delivered before the Washington Academy of Sciences on December 3 1914

and mechanical properties of the wood, on the geologist and soil physicist for the knowledge of sites suitable for the growth of different kinds of trees, upon the plant pathologist for the diseases of trees, upon the entomologist for the insect enemies of the forest, and so on

Such an impression is undoubtedly strengthened when the activities of such an organization as the Forest Service are considered. The placing under management of about 200 million acres of forest land has been an administrative problem of enormous magnitude. The administration of this vast public property involves many large industrial and economic questions, and affects intimately a number of varied and important interests—the lumber industry, the grazing industry, water power development, navigation, municipal water supplies, agricultural settlement, mining development and the railroads. In launching this first great public enterprise, undertaken in the face of very strong opposition, administrative activities appeared to overshadow research work. In this way doubtless many scientific men have gained the impression that forestry has little to do with science, which seeks for the causal relationship of things and for the establishment of laws and principles, that forestry is rather a patch work of miscellaneous knowledge borrowed from other sciences and assembled without particular system to help the practical administrator of forest property.

My endeavor in this paper will be to show that this impression is erroneous. While it is true that forestry as an art, as an applied science, utilizes results furnished by the natural and engineering sciences, while it is also true that the forester's activities—particularly during the pioneer period of establishing forest practice—may be largely administrative in

character, there is nevertheless a fundamental forest science which has a distinctive place. As with all others the science of forestry owes its distinctive character to its correlation from a certain point of view of parts of certain other sciences, such as mathematics, botany, entomology, civil engineering and chemistry. But these are only auxiliary to the resultant science—forestry—which rests upon a knowledge of the life of the forest as such, and which therefore depends upon the discovery of laws governing the forest's growth and development.

It is in this field chiefly that foresters may claim some scientific achievement, some contribution to general science. Sciences do not develop out of curiosity; they appear first of all because there are practical problems that need to be solved, and only later become an aim in themselves. This has been equally true of the science of forestry. The object of forestry as an art is to produce timber of high technical quality. In pursuing this object the forester very early observed that tall, cylindrical timber comparatively free of knots, is produced only in dense stands, in forests in which the trees exert an influence upon each other as well as upon the soil and climate of the area occupied by them. He further discovered that the social environment produced by trees in a forest is an absolutely essential condition for the continuous natural existence of the forest itself. If the forester had not found forests in nature, he would have had to create forests artificially in order to accomplish his practical purpose, since it is only through the control and regulation of the natural struggle for existence between trees in the forest that the forester is capable of managing it for the practical needs of man. Thus from the very nature of his dealings with the forest the forester was forced from

the beginning to consider the forest not merely as an aggregation of individual trees but as communities of trees—tree societies—and first from purely utilitarian reasons, developed a science upon which the practise of silviculture now rests

Forestry as a natural science, therefore, deals with the forest as a community in which the individual trees influence one another and also influence the character and life of the community itself. As a community the forest has individual character and form. It has a definite life history, it grows, develops, matures and propagates itself. Its form, development and final total product may be modified by external influences. By abuse it may be greatly injured and the forest as a living entity may even be destroyed. It responds equally to care and may be so molded by skillful treatment as to produce a high quality of product, and in greater amount and in a shorter time than if left to nature. The life history of this forest community varies according to the species composing it, the density of the stand, the manner in which the trees of different ages are grouped, the climatic and soil factors which affect the vigor and growth of the individual trees. The simplest form of a forest community is that composed of trees of one species and all of the same age. When several species and trees of different ages occupy the same ground, the form is more complex, the crowns overlapping and the roots occupying different layers of the soil. Thus, for instance, when the ground is occupied with a mixed stand of Douglas fir and hemlock, the former requiring more light, occupies the upper story, and because of its deeper root system extends to the lower lying strata of the soil. The hemlock, on the other hand, which is capable of growing under shade, occupies the understory, and having shallow roots utilizes largely the top soil.

There are forest communities, such for instance as those typical of northwestern Idaho, where western larch, Douglas fir, western white pine, white fir, western red cedar and hemlock will all grow together. Such a forest is evidently a very complex organism the stability of which is based on a very nice adjustment between the different classes and groups occupying the same ground. Any change in one of these classes or groups must necessarily affect the other. If, for instance, in the Douglas fir hemlock forest the Douglas fir is cut out, the remaining hemlock trees are likely to die out because their shallow roots are left exposed to the drying effect of the sun and wind. It is only by a thorough understanding of such mutual adjustments that the forester is capable of intelligently handling the forest. With the great number of species that are found in this country, with the great variety in climatic and other physical factors which influence the form of the forest, it is self evident that there are many forest communities each with distinctive biological characteristics, which offer a wide field for scientific inquiry. Amid the great volume of administrative phases of the work in the Forest Service this main objective has never been lost sight of in handling the national forests. The Forest Service is now spending nearly \$300,000 annually for research work, it maintains eight forest experiment stations and one thoroughly equipped forest products laboratory, and is doing this work solely to study the fundamental laws governing the life of the forest and their effect upon the final product—wood.

Forestry may be called tree sociology and occupies among natural sciences the same position as sociology among humanistic sciences. Sociology may be based upon the physiological functions of man as a biological individual. A physician, however, is not a sociologist, and social

phenomena can be understood and interpreted only in the light of sociological knowledge. So also with forestry. Forestry depends upon the anatomy and physiology of plants, but it is not applied anatomy and physiology of plants. With foresters, anatomy and physiology of plants is not the immediate end but enters only as one of the essential parts without which it is impossible to grasp the processes that take place in the forest. As the science of tree societies forestry really is a part of the larger science dealing with plant associations yet its development was entirely independent of botanical geography. When the need arose for the rational handling of timberlands no science of plant association was in existence. Foresters were compelled to study the biology of the forest by the best methods available, they used the general scientific methods of investigation and developed their own methods when the former proved inadequate. I am frank to admit that the present knowledge of plant associations in botany has not yet reached a point where foresters could leave wholly to botanists the working out of the basic facts about the life of the forests which are needed in the practise of forestry. When the general science of plant associations has reached a higher state of development, the two may possibly merge, but not until then.

In developing the science of tree associations, the forester has been unquestionably favored by the fact that the forests, being the highest expression of social plant life, afford the best opportunity for observing it.

The reason for the ability of forest trees to form most highly organized plant societies lies in their mode of growth. Each annual ring of growth, together with the new leaves that appear every year, are in reality new colonies of cells. Some of the

cells die toward the end of the vegetative season, others continue to live for a number of years. When the conditions of life in a forest have changed for a certain tree, when, for instance, from a dominant tree it became a suppressed one, the new colonies of cells formed during that year, and which sustain the life of that tree, are naturally adapted to these new conditions. The same is true when a suppressed tree, through some accident to its neighbors, comes into full enjoyment of light. The last annual growth is at once capable of taking advantage of the new situation created in the forest. Therefore, as long as the tree can form annual rings it possesses the elasticity and adaptability essential for trees living in dense stands. It is only when a tree is suppressed to a point when it can not form new growth that it dies and is eliminated from a stand. Because of the fact that the forest is the highest expression of social plant life, the foresters occupy the strategic position from which they command vistas accessible only with difficulty to other naturalists. In this lies the strength of forestry, its peculiar beauty and the debt which natural science owes to it. It is a significant fact, although, of course, only of historic importance, that, according to Charles Darwin¹ himself, it was "an obscure writer on forest trees who, in 1830 in Scotland (that is, 29 years before the 'Origin of Species' was published), most expressly and clearly anticipated his views on natural selection in a book on Naval Timber and Arboriculture." For the same reason it was foresters, who, long before the word "ecology" was coined, have assembled a vast amount of material on the life of the forest as a plant association—the basis of their silvicultural practise. Warming, Schimper, and other early writers on ecology, borrowed most of their

¹ "Origin of Species."

proofs and examples from the facts established by the foresters, and the forest literature of to day is still practically the only one which contains striking examples of the application of ecology to the solution of practical problems

One discovery recently made at the Wind River forest experiment station in Oregon comes particularly to my mind. In north-western Idaho where the western white pine is at its optimum growth and is greatly in demand by the lumberman, our former method of cutting was to remove the main stand and leave seed trees for the restocking of the ground. In order to protect the seed trees from windfall, they were left not singly but in blocks, each covering several acres. The trees left amounted often to from 10 to 15 per cent in volume of the total stand, and since they could not be utilized later they formed a fairly heavy investment for reforesting the cut over land. A study of the effect of these blocks of seed trees upon natural reforestation has proved that they can not be depended upon, at least within a reasonable time, to restock naturally the cut over land. The distance to which the seed is scattered from these seed trees is insignificant compared with the area to be reforested. Splendid young growth, however, is found here and there on cut over land, away from any seed trees, where the leaf litter is not completely burned. It is evident, therefore, that the seed from which this young growth originates must have come from a source other than the seed trees. The study of the leaf litter in a virgin stand showed that the latter contained on the average from one to two germinable seeds per square foot. Some of the seed found was so discolored that it must have been in the litter for a long time. Thus it was discovered that the seed of the western white pine retains its vitality for years while lying in the duff and litter beneath the mature stands, and

then germinates when the ground is exposed to direct light by cutting. It was found similarly that in old Douglas fir burns where the leaf litter was not completely destroyed, the young growth invariably sprung up from seed that had escaped fire and had been lying dormant in the ground. Should a second fire go through the young stand before it reaches the bearing stage, the land may become a complete waste, at least for hundreds of years, although there may be seed trees left on the ground. This conclusively proves that the young growth comes from the seed stored in the ground before cutting took place and not from the seed scattered after cutting by the seed trees left.

The wonderful capacity of the leaf litter and duff of the cool, dark forests of the Northwest to act as a storage medium for the seed until favorable conditions for its germination occur is confined not only to the Douglas fir and western white pine but to the seed of other species which often grow together with them, such as Noble fir, amabilis fir, western red cedar and hemlock. The subsequent appearance of other species in a Douglas fir or western white pine stand depends apparently to a large extent upon the seed stored in the ground at a time when the original forest still existed. This discovery revolutionizes our conception of the succession of forest stands since it shows that the future composition of the forest is determined by the seed stored in the leaf litter, and the appearance of seedlings first of one species and then of another results simply from the differences in the relative endurance of seed of the different species that are lying in the ground. Besides being of scientific importance this discovery has also a great practical significance. It accentuates the disastrous consequence of a second fire in an old burn because no more seed remains in the ground while the capacity of the few

seed trees that may be on the burn is very limited in restocking the ground. This discovery enabled the service to change materially the present methods of cutting in the white pine and Douglas fir forests to the mutual advantage of the government and of the logging operators.

I shall give briefly a few other illustrations of the life of the forest which stamp it as a distinct plant society.

The first social phenomenon in a stand of trees is the differentiation of individuals of the same age on the basis of differences in height, crown development and growth, the result of the struggle for light and nourishment between the members of the stand. A forest at maturity contains scarcely 5 per cent of all the trees that have started life there. Yet the death of the 95 per cent is a necessary condition to the development of the others. The process of differentiation into dominant and suppressed trees takes place particularly in youth and gradually slows down toward maturity. Thus in some natural pine forests during the age between 20 to 80 years over 4 000 trees on an acre die, whereas at the age between 80 and 100 only 300 trees die. With some trees this natural dying out with age proceeds faster than with others. Thus in pine, birch, aspen and all other species which demand a great deal of light the death rate is enormous. With spruce, beech, fir and species which are satisfied with less light this process is less energetic. The growing demand for space with age by individual trees in a spruce forest may be expressed in the following figures:

	Sq. Ft.
At 20 years of age	4
At 40 years of age	34
At 60 years of age	70
At 80 years of age	110
At 100 years of age	150

If we take the space required by a pine at the age between 40 and 50 years as 100,

then for spruce at the same age it will be 87 for beech 79 and for fir 63. This process of differentiation is universal in forests everywhere.

Another peculiarity that marks a tree community is the difference in seed production of trees which occupy different positions in the stand. Thus if the trees in a forest are divided into five classes according to their height and crown development and if the seed production of the most dominant class is designated as 100, the seed production for trees of the second class will be 88, for the third class 33, for the fourth class only 5 per cent, while the trees of the fifth class will not produce a single seed, although the age of all these trees may be practically the same. The same struggle for existence, therefore, which produced the dominant and suppressed trees works toward a natural selection, since only those which have conquered in the struggle for existence and are endowed with the greatest individual energy of growth reproduce themselves.

In a forest there is altogether a different climate, a different soil and a different ground cover than outside of it. A forest cover does not allow all the precipitation that falls over it to reach the ground. Part of the precipitation remains on the crowns and is later evaporated back into the air. Another part, through openings in the cover, reaches the ground, while a third part runs down along the trunks to the base of the tree. Many and exact measurements have demonstrated that a forest cover intercepts from 15 to 80 per cent of precipitation according to the species of trees, density of the stand, age of the forest and other factors. Thus pine forests of the north intercept only about 20 per cent, spruce about 40 per cent, and fir nearly 60 per cent of the total precipitation that falls in the open. The amount that runs off along the trunks in some species is very

small—less than 1 per cent. In others, for instance beech, it is 5 per cent. Thus if a certain locality receives 50 inches of rain, the ground under the forest will receive only 40, 30 or 20 inches. Thus 10, 20 and 30 inches will be withdrawn from the total circulation of moisture over the area occupied by the forest. The forest cover, besides preventing all of the precipitation from reaching the ground, similarly keeps out light, heat and wind. Under a forest cover, therefore, there is altogether a different heat and light climate and a different relative humidity than in the open.

The foliage that falls year after year upon the ground creates deep modification in the forest soil. The changes which the accumulation of leaf litter and the roots of the trees produce in the soil and subsoil are so fundamental that it is often possible to determine centuries after a forest has been destroyed, whether the ground was ever occupied by one.

The effect which trees in a stand have upon each other is not confined merely to changes in their external form and growth; it extends also to their internal structure. The specific gravity of the wood, its composition and the anatomical structure which determines its specific gravity differ in the same species, and on the same soil, and in the same climate, according to the position which the tree occupies in the stand. Thus in a 100 year old stand of spruce and fir the specific gravity of wood is greatest in trees of the third crown class (intermediate trees). The ratio of the thick wall portion of the annual ring to the thin wall of the spring wood is also different in trees of different crown classes. The difference in the size of the tracheids in trees of different crown classes may be so great that in one tracheid of a dominant tree there may be placed three tracheid cells of a suppressed tree. The amount of

lignin per unit of weight is greater in dominant trees than in suppressed trees.

Forest trees in a stand are thus influenced not only by the external physical geographical environment, but also by the new social environment which they themselves create. For this reason forest trees assimilate grow and bear fruit differently and have a different external appearance and internal structure than trees not grown in a forest.

Forestry, unlike horticulture or agriculture, deals with wild plants scarcely modified by cultivation. Trees are also long lived plants, from the origin of a forest stand to its maturity there may pass more than a century. Foresters, therefore, operate over long periods of time. They must also deal with vast areas, the soil under the forest is as a rule unchanged by cultivation and most of the cultural operations applicable in arboriculture or agriculture are entirely impracticable in forestry. Forests therefore are largely the product of nature, the result of the free play of natural forces. Since the foresters had to deal with natural plants which grew under natural conditions, they early learned to study and use the natural forces affecting forest growth. In nature the least change in the topography, exposure or depth of soil, etc., means a change in the composition of the forest in its density, in the character of the ground cover, and so on. As a result of his observations, the forester has developed definite laws of forest distribution. The forests in the different regions of the country have been divided into natural types with corresponding types of climate and site. These natural forest types, which by the way were also developed long before the modern conception of plant formations came to light, have been laid at the foundation of nearly all of the practical work in the woods. A

forest type became the silvicultural unit which has the same physical conditions of growth throughout and therefore requires the same method of treatment. The manner of growth and the method of natural regeneration once developed for a forest type hold true for the same type no matter where it occurs. After the relation between a certain natural type of forest and the climate and topography of a region has been established the forest growth becomes the living expression of the climatic and physical factors of the locality. Similarly with a given type of climate and locality it is possible for the forester to conceive the type of forest which would grow there naturally. The forester therefore may speak of the climate of the beech forest of the Engelmann spruce forest of the yellow pine forest. Thus if in China which may lack weather observations we find a beech forest similar to one found in northern New York we can be fairly certain of the climatic similarities of the two regions. More than that a type of virgin forest growth may serve as a better indication of the climate of a particular locality than meteorological records covering a short number of years. A forest which has grown on the same ground for many generations is the result not of any exceptional climatic cycle but is the product of the average climatic conditions that have prevailed in that region for a long time. It expresses not only the result of one single climatic factor but is the product of all the climatic and physical factors together. Similarly the use of the natural forest types for determining the potential capacity of the land occupied by them for different purposes is becoming more and more appreciated. When the climatic characteristics of a certain type of forest for instance those of Engelmann spruce in the Rocky Mountains is thoroughly established the potential

capacity of the land occupied by it for agriculture grazing or other purposes is also largely determined.

Observations of the effect of climate upon forest growth naturally brought out facts with regard to the effect of forests upon climate soil and other physical factors and led to the development of a special branch of meteorology known as forest meteorology in which the foresters have taken a prominent part. While there are some phases in forest meteorology which still allow room for disagreement some relations established by foresters are widely accepted. One of these is the effect which forests have upon local climate especially that of the area they occupy and of contiguous areas. Every farmer who plants a windbreak knows and takes advantage of this influence. Another relation is that between the forest and the circulation of water on and in the ground a relation which plays such an important part in the regimen of streams. Still a third one as yet beyond the possibility of absolute proof is the effect of forests in level countries in the path of prevailing winds upon the humidity and temperature of far distant regions lying in their lee.

If in the field of botany the forester has contributed to the progress of botanical geography and in the realm of meteorology has opened new fields of investigation his influence in wood technology has been in changing entirely the attitude of engineers physicists and chemists in handling wood products. The methods of studying the physical mechanical and chemical properties of wood were of course those used in engineering by chemists and physicists but the forester has shown that wood unlike steel concrete or other structural material is subject to altogether different laws. Wood he has shown is not a homogeneous product but is greatly influenced by the

conditions in the stand from which it comes. Were it not, therefore, that mechanical properties can be tied up with some definite forest conditions and correlated with some readily visible expression of tree growth, such as the number of rings per inch or the specific gravity of the wood, timber would be too much of an indefinite quantity for architects and other users of wood to handle with perfect safety. To find such a relation is just what the foresters have been attempting to do and most of the studies of the strength of wood have been with the view of establishing certain relations between the mechanical, physical and anatomical properties of the wood. Some of these relations I may mention here.

One of the earliest relations which foresters have established with a fair certainty is that between the specific gravity of the wood and its technical qualities. Some of the foresters even go so far as to claim that the specific gravity of wood is an indicator of all other mechanical properties and that the strength of wood increases with the specific gravity, irrespective of the species and genus. In other words, the heavier the wood, all other conditions being equal, the greater its strength. Even oak, which formed apparently an exception, has been recently shown to follow the same law. If there is still some doubt that the specific gravity of wood can be made a criterion of all mechanical and technical properties of wood, the correlation between the specific gravity and the resistance to compression end wise (parallel to the grain) is apparently beyond question. Thus by the specific gravity the resistance to compression end wise can be readily determined. The compression end wise equals 1,000 times the specific gravity minus 70, when the moisture contents of the wood is 15 per cent, or $C = 1,000S - 70$.

Since in construction work the most de-

sirable wood is the one which possesses the highest strength at a given weight, the ratio between the compression strength and the specific gravity was found to express most clearly the strength of wood. This ratio, however, increases with the increase in the specific gravity, a fact which further substantiates the law that the specific gravity of wood determines its mechanical properties.

Another relation which has been fairly established is that between the resistance to compression end wise and the bending strength of timber. (By the resistance compression end wise, therefore, the bending strength of timber can be determined.)

One of the other properties of wood, namely hardness, was found to have a definite relation to the bending and compression strength of wood and this fact tempts the conclusion that by hardness alone all other mechanical properties can be determined. The test for hardness is very simple; it can be made even by a small manufacturer and therefore the whole problem of wood testing would be greatly simplified. Hardness was also found to have a definite relation to the proportion of the summer wood in the annual ring and consequently to the specific gravity of the wood. The specific gravity of wood is determined by its anatomical structure, by the proportion of fibrovascular bundles, their thickness and length, the proportion of thick walled cells, medullary rays, etc. The anatomical structure in its turn is probably determined by the combination of two factors—the amount of nourishment in the soil and the intensity of transpiration. The mechanical properties of wood come, therefore, within the control of the forester who raises and cares for the forest.

There is another field of scientific endeavor in which foresters in this country may claim some credit. This is in the field

of forest mathematics. One unfamiliar with forest growth can hardly realize the difficulties in the way of measuring the forest crop, the amount of wood produced in a forest composed, for instance, of many different species, sizes and ages. If a tree resembled any geometric body, such as a truncated cone, or an Apollonian paraboloid, it would be a simple matter to determine its contents by applying the formula for such body. But a tree's form does not coincide with that of any known geometric body, so that it would seem that the only possible way of determining the contents of the trees forming a forest would be by measuring each single tree. Evidently this would be an entirely impracticable task.

The common practise of determining the contents of trees either in board measure or in cubic feet is to measure a large number of trees of a given species in a given locality and apply the average figures to the trees of the same diameters and heights within that locality. Since there are, however, a great many species of trees in this country, some of which have a very wide geographic range, this method necessarily involves the preparation of a large number of local volume tables and hence the measurement of hundreds of thousands of trees. The measurement of the taper of a large number of trees has shown that there are certain critical points along the stem of a tree, the ratio between which expresses the form of the tree in a sufficiently accurate manner. It was found that trees having the same total height, the same diameter breast high ($4\frac{1}{2}$ feet from the ground), and the same ratio between the diameter at half the height of the tree and the diameter breast-high, must invariably have the same cubic contents irrespective of the species of the tree or the region in which it grows. Thus whether it be a Scotch pine of northern Sweden, a yellow

pine of Arizona, a mahogany of the tropics, or a scrubby birch of the Arctic Circle, the volume of the tree may be expressed by means of one simple relationship. The discovery of this very simple relation provides for the first time a basis for the construction of a universal volume table. The mathematicians of the earlier period sought in vain to find a formula by which the cubic contents of a tree could be expressed. What the mathematicians failed to develop by the deductive method, foresters have found by the inductive method. With a reliable table for converting cubic measure into board measure for trees of different sizes the universal volume table expressed in cubic feet could be translated into a universal table expressed in board feet, which is the measure peculiar to this country.

There is another contribution of which I am somewhat hesitant to speak for it is not a contribution to pure science, if by science is meant only the physical or natural sciences. Since, however, it touches the interests of a large number of people, I may be forgiven if I say a few words about it. It is a contribution to what one economist has aptly called the "science of social engineering." The transfer of the forest reserves in 1905 to the Department of Agriculture marked a new departure in the national economic life. It recognized the new principle that the nation's resources should be managed by the nation and directly in the interests of the whole people, it recognized that these resources should be developed collectively rather than individually and indirectly. Nearly ten years have now passed since the inauguration of this policy. The record of what has been accomplished and the manner in which many of the problems have been approached and solved must unquestionably be considered a contribution to the methods by which similar problems may be handled by the nation in the

future In the administration of the national forests there is being developed gradually what I believe to be a truly scientific system for attaining a concrete economic end and a system of controlling certain correlated industries with a single purpose in view—the maximum of the welfare of the nation as a whole In spite of many mistakes which we have undoubtedly made and which we have attempted to correct as we went along in spite of the lack of practice and experience in solving the problems at hand this new policy, it seems to me has already proved entirely safe and workable

HENRY S GRAVES

U S FOREST SERVICE

MATHEMATICS ASTRONOMY AND PHYSICS AT THE CALIFORNIA MEETING

A JOINT session of the American Mathematical Society the American Astronomical Society and Section A of the American Association for the Advancement of Science will be held on Tuesday August 3 at the University of California for the presentation of two addresses

The Human Significance of Mathematics by Professor C J Keyser Columbia University New York

The Work of a Modern Observatory by Dr George E Hale Mount Wilson Solar Observatory

On Friday August 6 the American Astronomical Society and others interested in astronomical research will make an excursion to the Lick Observatory Mount Hamilton near San Jose The director of the Mount Wilson Solar Observatory near Pasadena extends a cordial invitation to men of science interested in astronomical and physical research to visit the observatory either before or after the San Francisco meeting of the association

Physicists are invited to attend a joint session for mathematics astronomy and physics on Tuesday August 3 One session of the meetings devoted to physics will give consideration to recent spectroscopical investigations

On the occasion of the visit of the association to Stanford University on Wednesday, August 4 Professor Harris J Ryan will give demonstrations with high potential electric currents in the new laboratory which has been equipped for high potential experimentation.

SCIENTIFIC NOTES AND NEWS

DR CHARLES H HERTY professor of chemistry in the University of North Carolina has been elected president of the American Chemical Society for the year 1915 The address of the retiring president Professor Theodore W Richards of Harvard University written for the Montreal meeting of the society which was abandoned on account of the war has been printed in the *Journal of the American Chemical Society* for December The subject is

The Present Aspect of the Hypothesis of Compressible Atoms

THE Perkin medal of the Society of Chemical Industry will be conferred on Dr Edward Weston on the evening of January 22 at the Chemists Club New York City Dr Charles F Candler will present the medal and an address will be made by Dr L H Baekeland

On January 20 1915 the Medical Society of the District of Columbia held a memorial meeting in honor of the late Dr A F A King who died on December 13 1914 The following appreciations were presented In Memoriam Resolutions by Committee Dr D S Lamb Biographical Sketch Dr Henry D Fry Dr King as an Author Dr Barton Cooke Hirst Doctor King on Mosquitoes and Malaria Dr L O Howard Doctor King as a Teacher Dr Sterling Ruffin Doctor King as Dean of the Medical School Dr D K Shute, Personal Characteristics Dr A R Shands

THE Rev Sir John Twisden formerly professor of mathematics in the Staff College of the British army has died at the age of nearly ninety years

M ALFRED FOURNIER formerly professor of dermatology and syphiligraphy at the University of Paris has died at the age of eighty two years

BRITISH New Year's honors include two knightships conferred on scientific men—Dr James Johnstone Dobbie, F.R.S., principal of the government laboratories, formerly professor of chemistry at the University College of North Wales, and Frank Watson Dyson, F.R.S., astronomer royal since 1910.

DR. HENRY S. DRINKER, president of Lehigh University, was re-elected president of the American Forestry Association at the meeting held in New York City last week.

HERR KARL BENZ, founder of the German automobile firm Benz and Company, has been given the doctorate of engineering by the Technical Institute of Karlsruhe.

THE council of the Geographical Society of Philadelphia has authorized the holding of monthly meetings for study and research, in addition to the usual illustrated lectures on travel and exploration. The first of these meetings was held on the evening of January 15, when Professor D. W. Johnson, of Columbia University, addressed members of the society on "The Physiographic Features of Western Europe and Their Influence on the Campaign against France." Professor Johnson has also given illustrated lectures on the same subject recently before the New York Academy of Sciences, the Brooklyn Institute of Arts and Sciences, and the American Geographical Society.

"OUR Natural Resources: Their Economic Significance," is the subject of a series of illustrated lectures to be given by Associate Professor J. Paul Goode, of the department of geography in the University of Chicago, beginning January 11 at the Berwyn center of the University Lecture Association. The purpose of the course is to discuss the great resources of the country from the point of view of their physical origin, and to trace the influence of these physical conditions on our daily social life. The subjects of the individual lectures are as follows: "The Evolution of a Continent," "Our Obligation to the Forest," "The Age of Steel," "The Social Significance of Wheat," "The Reclamation of Arid Lands," and "When the Coal is Gone."

AN illustrated lecture was given by Professor R. D. Salisbury, dean of the Ogden School of Science, University of Chicago, on January 8, before the Southern Geographical Society, Knoxville, Tennessee. The subject of the lecture was "In and About Patagonia," and related to views and experiences of a stay of two months in that region for certain studies in connection with the Geological Survey of Argentina.

JOHN A. MATHEWS, Ph.D., Sc.D., general manager of the Halcumb Steel Company, will deliver on February 1, an illustrated address upon "Iron in Antiquity and To-day" before the Syracuse University chapter of Sigma Xi and the Syracuse branch of the Archeological Institute of America of which Dr. Mathews is vice president. The lecture will be illustrated and the date is February fifth.

WE learn from foreign journals that the memorial at Finse, Norway, in honor of Captain Scott and his companions was unveiled on December 28 by Dr. Skattum, vice president of the Norwegian Geographical Society. The memorial has taken the form of a monument about 20 feet high bearing the names of the explorers—Captain R. F. Scott, Dr. Wilson, Captain L. E. G. Oates, Lieutenant H. R. Bowers, and Petty Officer Evans—and an inscription reading "Erected by Norwegians in honor of Antarctic research and heroic courage."

DR. J. W. SPENGLER, professor of zoology at Giessen, has been elected a foreign member of the Royal Upsala Academy of Sciences.

DR. JOHANN HJORT, director of the fisheries of Norway, lectured before the Washington Academy of Sciences and the Biological Society of Washington on January 19, his subject being "Migrations and Fluctuations of the Marine Animals of Western Europe."

AN English correspondent informs us that Professor Albrecht Penck, who, since his return from Australia with a load of geographical information, had been detained in London by the British government, was allowed to go back to Berlin on December 31, since it no longer seemed probable that the Germans

would have any opportunity for making his tile use of his knowledge. While in London Professor Penck has been given all facility for his studies in the government museums and libraries and in the rooms of the Geological Society of London

ACCORDING to *Das Umschau* Dr Oskar Idenzeller and his wife sent last year by the Hamburg Museum of Ethnology to make explorations in northern Siberia have been imprisoned. The St Petersburg Academy of Sciences has sent a protest to the Russian minister of the interior

THE Cutter Lectures in Preventive Medicine for the year 1915 will be given at the Harvard Medical School by Dr Victor C Vaughan professor of hygiene and physiological chemistry and dean of the school of medicine and surgery of the University of Michigan and Dr Joseph Goldberger surgeon United States Public Health Service Washington D C. Dr Vaughan will lecture on

The Phenomena of Infection on April 14 15 and 16. Dr Goldberger's subject will be Diet and Pellagra and will be given in one lecture on April 2. These lectures are given annually under the terms of a bequest from John Clarence Cutter whose will provided that the lectures so given should be styled the Cutter Lectures on Preventive Medicine and that they should be delivered in Boston and be free to the medical profession and the press. Others interested are cordially invited.

DR CLINTON WAGNER formerly a well known physician of New York and first professor of laryngology and rhinology in the New York Post Graduate Medical School has died in Switzerland at the age of seventy four years.

SIR ROBERT SIMON professor of therapeutics in the University of Birmingham has died at the age of sixty four years.

DR KARL SCHNABEL formerly professor in the Prussian mining school at Clausthal has died at the age of seventy two years.

PROFESSOR OTTO SACKUR has been killed by an explosion in the laboratory of the Kaiser Wilhelm Institute at Dahlen where experi-

ments in high explosives were being conducted.

DR HERBERT STANGE docent for chemistry at Giessen and Dr F W Hinrichsen docent for chemistry at the Berlin Technical School have been killed while serving as lieutenants in the German army.

DR M HEYDE docent for surgery at Marlburg and Dr Karl Muller assistant in the Institute of Oceanography at Kiel have died from typhoid fever contracted while serving as physicians with the German army.

THE Civil Service Commission of Cook County Ill will hold an examination during the latter part of January 1915 for the position of director of the Psychopathic Institute of the Juvenile Court. The director is required to make a thorough physical and mental examination including laboratory and psychological tests of the delinquent and dependent children referred to the institute by the court and must interpret the tests and make reports of the examinations for the guidance of the judge in deciding the cases. The position pays \$5 000 per year and any citizen of the United States may apply for entrance to the examination but the applicants should have a medical degree or at least an experience in nervous and mental diseases in practical psychology or in psychopathic work among juveniles or adults either in connection with courts or clinics. Persons interested in the examination may secure applications by addressing Cook County Civil Service Commission Chicago Illinois.

THE report of the proceedings of the general committee for promoting the establishment of an Imperial College of Tropical Agriculture is referred to in the *Pioneer Mail* of December 4 and quoted in *Nature*. It is stated that Mr R N Lyne director of agriculture Ceylon says he thinks that the West Indies will now support Ceylon's claims to be the home of the college. The committee resolved to take steps to raise £40 000 for building and endowing the college of which £20 000 should be asked from the governments concerned including India, and the remainder be raised by public sub-

scriptions, provided governments contribute the share stated. It was also resolved to collect £5,000 for the erection of a hotel for European students. The committee has not selected Ceylon for the site, at the same time it favors that country.

THE weekly French scientific journal, *La Nature* which suspended publication at the beginning of August, began again on December 12.

DR O P HAY, research associate of the Carnegie Institution of Washington, D C, who is making a study of the Pleistocene vertebrates of North America for the institution, delivered before the Science Club of the University of Texas on December 21 an illustrated lecture entitled "The vertebrate fauna of the Pleistocene epoch." Dr Hay called attention to the characteristic mammoth, mastodon, sloths, bison and horses of the Pleistocene, showing illustrations of the skeletons, jaws, and restorations of the more prominent species. A series of maps was exhibited showing the distribution of the various species during various stages of the Pleistocene.

UNDER the auspices of the department of geology and geography of Harvard University a series of five public lectures will be given in the geological lecture room, University Museum at 4 P M. These lectures have been arranged in response to a real interest in the influence which geographic conditions have or may have upon the present European war.

Monday January 18—"The Physical Geography of Central and Western Europe" (Illustrated) Professor William M Davis.

Wednesday, January 20—"Some Military Features along the Western Front" Professor Robert M Johnston.

Monday January 25—"European Weather and the War" Professor Robert DeC Ward.

Wednesday, January 27—"The Food Supply in Europe" Professor Thomas N Carver.

Friday January 29—"Mineral Resources of Central and Western Europe" Professor Henry L Smyth.

In connection with these lectures certain maps and charts of special geographic interest will be displayed in the lecture room, which will be open at 8.30 on the days of the lectures.

THE legislature efficiency committee, in its report on the administrative system of Illinois which appeared December 7, makes according to the *Journal* of the American Medical Association the following recommendations. The reorganization of the various health agencies into a state health department to be under the direction of a salaried health commissioner; an unpaid state health board of five officers to be appointed by the governor, the state health department to have supervision over the examination and licensing of physicians, pharmacists, dentists and nurses and the regulation of those organizations which carry on other professions and trades for the protection of public health, a small board or committee to be provided for each profession to arrange for examinations, issue licenses and to revoke same for cause, the clerical and administrative work in connection with such examinations to be handled through one office and the action of the examining boards in revoking licenses, to be subject to review by the state board of health. The board of barbers' examiners to be abolished and the power of sanitary control over barbers to be exercised by the health department, the law for the collection of vital statistics to be made more effective, the pharmacy law to be revised, the cold storage of food products to be regulated and a state sanitary code to be enacted.

PART of the government's exhibit for the Panama California exposition at San Diego leaves Washington this week. This portion has to do with the national forests of New Mexico, and will be shown in the New Mexico building the exhibit having been prepared in cooperation with the state board of exposition commissioners of that state. The material also shows specimens of the principal timber trees of New Mexico and their uses. Other exposition material is to leave soon for San Francisco where it will form a part of the Panama Pacific exposition. Part of this is being prepared through cooperation between the forest service and the United States civil service commission. The commission passes on the qualifications of all candidates for

positions in the forest service, testing the fitness of those who wish to become forest officers through outdoor examinations in riding, surveying, timber estimating, and similar matters as well as by more conventional methods, its exhibit will illustrate the duties of these officers. Cooperation also exists in the preparation of exhibit material, between the forest service and the bureau of education. This shows how forest subjects are used in the public schools, in connection with nature study, commercial geography, agriculture and the like. One of the exhibits is a display made by the normal school pupils of the District of Columbia, in which a number of those who are studying for teachers' positions entered a prize contest on tree study. Each of the contestants prepared a separate exhibit showing the life history and the products of individual trees, such as white pine, hickory or sugar maple.

UNIVERSITY AND EDUCATIONAL NEWS

POMONA COLLEGE, Claremont, Cal., has completed the collection of an endowment fund of one million dollars toward which the General Education Board contributed \$150,000.

MRS. RUSSELL SAGE, who had undertaken to give \$100,000 towards a \$500,000 dining hall for Princeton University, has increased her offer to \$250,000, provided an equal sum is collected by July 1. Sums amounting to \$75,000 have been subscribed, of which \$30,000 are due to efforts of the sophomore class.

By the will of the late Dr. T. Bell, of New Castle, the sum of \$3,000 is bequeathed to the Armstrong College.

DR. P. J. ANDERSON, formerly field pathologist with the Pennsylvania commission for the investigation and control of the chestnut blight disease, has been appointed instructor in botany at the Massachusetts Agricultural College.

DR. HARRY M. ULLMANN has been made professor of chemistry at Lehigh University, in charge of the department. Ralph J. Fogg, assistant professor in the department of civil engineering, has been made associate professor

DISCUSSION AND CORRESPONDENCE

OCCURRENCE OF SILVER SCURF OF POTATOES IN THE SALT LAKE VALLEY, UTAH

WHILE making a plant disease survey in the Salt Lake Valley, Utah, during the past season the writer's attention was called to some diseased potatoes, which, upon examination, proved to be infected with the silver scurf fungus (*Spondylocodadium atrovirens* Hartz). Microscopic examination of the organism together with the study of the fungus in pure culture proved its identity beyond a doubt. Both the conidial and sclerotial stages were found in great abundance on potato tubers collected from various parts of the valley. The conidia are dark brown and elongate ovate with the apex narrowed and subhyaline. They are found to be five to eight celled, and average approximately 42 microns in length by about 8½ microns in diameter. A large number of measurements gave lengths ranging from 30 to 75 microns, and diameters ranging from 6 to 11 microns. The conidia are borne in more or less irregular whorls on the upper half of the conidiophores which vary considerably in length, but averaging about 125 microns. In addition to the characters of the fungus, the typical appearance of infected spots on the tubers leaves no doubt as to the identity of the disease, the silvery or glistening appearance of the spots showing very plainly. The presence of the minute black sclerotia is also very characteristic. Typical specimens of discolored, shrunken and shriveled tubers showing the later stages of the disease were also found in considerable abundance.

Very little is to be found on this disease in American plant pathological literature. It was first seen by Clinton¹ in 1907, Orton² mentions it as spreading rapidly in the eastern states, Melhus³ states that the disease has been found on potatoes from Maine, Vermont, New York, Virginia, West Virginia,

¹ Clinton, G. P., Connecticut Agricultural Experiment Station, Annual Report, 1908.

² Orton, W. A., Farmers' Bulletin No. 544, U. S. Department of Agriculture.

³ Melhus, I. E., Circular No. 127, Bureau of Plant Industry, U. S. Department of Agriculture.

Florida, Wisconsin and Kansas. Recently silver scurf has been reported from Oregon⁴ and Washington⁵. It has been very difficult to trace the introduction of this disease into Utah for the reason that the potato growers are not always informed as to the source of their seed tubers. In most cases the seed was said to have been purchased from other points within the state of Utah, but in some instances it was definitely ascertained that the seed came from Idaho. It is certain, therefore, that seed planted on new soil, with the resultant crop developing the disease, must have been infected previous to being planted. The writer believes that the silver scurf disease of the potato is widespread throughout the intermountain states particularly in Utah and Idaho. P. J. O'GARA

December 9, 1914

A SIMPLE DEVICE FOR COUNTING SEEDS

In preparing tests of seed germination a great deal of rather monotonous work is required in counting the seeds. The device to be described was worked out to obviate part of this labor, and has proved very efficient in our seed laboratory. In the hope that it will save valuable time for other workers in this field the following description is presented

The seed counter is made from a piece of brass or copper tubing 20 cm in length and about 5 cm in diameter. This is bent in the middle at an angle of 45° and then on one

⁴ Bailey, F. D., *Phytopathology*, 4: 321-322, August, 1914

⁵ Rees, H. L., *Western Washington Experiment Station Bulletin*, 1: 15-16, 1914

side filed almost paper thin for a distance of 8 cm. At intervals of 7 cm on this flattened side ten holes of suitable diameter are punched with a needle and hammer. One end of the tube on the side nearest the holes is sealed with solder or sealing wax, and the other end is connected by 5 cm rubber pressure tubing to a small Richards air pump.

The seeds to be counted are placed in a flat tray and the pump started. The suction through the fine openings holds the seeds in lots of ten to the tube which are removed by a flick of the finger. In case more than one seed adheres to a hole the extra ones can be quickly removed by tapping the tube, or with the finger. It will be found advisable to have tubes made up with various sizes of holes, one for small seeds such as tobacco, with openings as small as can be made with a No. 7 needle, one with medium sized holes of 5 mm, which are best adapted to seeds of the size of radish, clover, etc. and one with holes of 1 mm in diameter. Seeds with a very rough exterior such as beet seed do not lend themselves well to this method of counting as the surface is too uneven to be held by the suction. Large seeds—beans, peas and corn for instance—are too heavy to be held by the suction produced by the small Richards pump, but there is no doubt that with a stronger suction such as that produced by a vacuum cleaner this method could be used in counting these heavier seeds.

THE JOURNAL "ISIS"

TO THE EDITOR OF SCIENCE. I beg to call your attention to one of the incidents of the war which is likely to be overlooked in the midst of all the excitement of daily battles and the destruction of life and property. I refer to the devotion to scholarship, to duty, and to educational ideals shown by Dr. G. Sartorius, of Wondelgem lez Gand, editor of *Isis*, in continuing the publication of this im-

portant journal in spite of the invasion of his city and country, and under circumstances that must be most trying. *Isis* was founded in 1913, its purpose being to consider the historical development of all the various human disciplines, a field not covered by any other publication. It appears about four times a year, is edited in a dignified and thoroughly scholarly manner, and takes rank with the best scientific periodicals of the day. Its articles appear in the four languages of the various international congresses, but the editorial matter is in French. It should have place in every general reading room, and particularly in the libraries of all institutions of higher learning.

It occurs to me that this is the time of all times to encourage a Belgian scholar of international standing, struggling to continue so important a publication. I have been glad to send my own subscription in advance, and I shall be glad to forward such subscriptions as may be sent to me. The price is \$3 a year (\$6 for Vol. I) and if one should wish the journal from the beginning \$12 would pay for the back numbers and one year in advance.

I undertake this work merely to help a worthy cause, but without any personal guarantee as to the effect of the war upon the enterprise. I have been glad to send my own money, and I hope others will join in the worthy cause.

SCIENTIFIC BOOKS

Anesthesia. By JAMES TAYLOR GWATHMEY, M.D. and CHARLES BASKERVILLE, Ph.D., F.C.S. New York and London, D. Appleton and Co. 1914. Pp. xxxii + 945. Illustrated.

The subject of anesthesia in surgical operations has attracted the attention of medical men and others for three quarters of a century. Between 1840 and 1850 the successful use of ether was introduced in this country, and of chloroform in Great Britain. Although other substances were soon after recommended for general anesthesia, some of

which came into limited use these two well-known liquids have remained the standard agencies for the production of insensibility to pain in operations practically down to the present time.

In recent years, however, there has been a widening of the field, largely because of new discoveries and the introduction of local anesthetics to supplant, in many cases, the earlier ones with profound general effects. A voluminous literature has been accumulating, not only in the way of papers, but also in the form of longer treatises. Most of this has been of interest to medical men only and has been written for those engaged in some field of medical or surgical work.

But in this country the whole subject of anesthesia has become of more popular interest as witness the discussions in the monthly magazines, and even in the daily press, on the subject of the "twilight sleep" in its relations to midwifery. At the present time the newspapers bring us many accounts of the difficulties of surgery on the European battlefields, where the supply of ether and chloroform is sometimes insufficient for the needs. Medical men and laymen alike have been ready for a discussion of the whole subject of anesthesia along somewhat broader lines than obtained in the past literature and such a discussion is found in the work which is the subject of this review. The authors bring a wide range of experience to the task. One of them is a specialist who has done much to perfect the technique of the administration of certain anesthetics, and who has been one of the foremost advocates of the proposition that the administration of an anesthetic is in itself an operation calling for special skill and experience, and which should not be turned over to any interne or advanced student who happens to be at hand. The other author is one of our well-known chemists who has had an extended and unique experience in the preparation and the study of the properties of a group of pure anesthetics. He is the author of a number of valuable articles on the subject of pure anesthetics.

The work therefore, brings evidence of

first hand knowledge trustworthy in detail Besides this the recorded experience of prominent writers is condensed and presented in such a way as to make the book a reference work covering a wide range of topics in which the historical treatment is a prominent feature The literature references are very full and sufficient to afford the specialist a ground work for following up the details of any given topic

As much of the work in modern anesthesia is of a somewhat special character which could not be well covered by one or two writers the authors have wisely called on men especially expert in their lines to contribute certain chapters In this way anesthesia by colonic absorption local anesthesia intra venous anesthesia and spinal analgesia and spinal anesthesia have been specially treated Some of these topics the last one for example have been much debated and the authors have presented the views of the opponents as well as the friends of the innovations It can not be said that a partisan attitude appears markedly anywhere in the book There are also chapters on the application of hypnotism and mental suggestion to the production of anesthesia and one on the medico legal status of the anesthetist The reviewer will not attempt to pass on the merits of these more special discussions They are referred to in order to give an idea of the range of topics covered in the work

Of more special interest to chemists and the general scientist are the chapters giving lists of all the anesthetics which have been in use with extended notes on the properties and behavior of the more important ones The discussions on the chemistry of ether and chloroform are especially full Here we find a good summary of the work of Dr Baskerville There can be no question of the value of this part of the work to any one who wishes to become familiar with the chemical phases of the subject of anesthetics

While the book as a whole will find its most numerous readers among medical men it may be cordially recommended to the general scientific student who may be interested in

securing a comprehensive view of the important field
J H LONG

Food Products By HENRY C SHERMAN,
Ph D Professor of Food Chemistry Columbia University New York The Macmillan Company 1914 Pp 594 Price \$2 25

The author's purpose is stated as follows 'In this volume it is sought to incorporate in the subject matter of a general study of foods the results of these recent advances which heretofore have been too widely scattered to be readily accessible The author's experience as a teacher has shown him how difficult it is to find the material one needs for a comprehensive study of foods He has rendered important service to his fellow teachers and to all who are interested in the scientific study of foods in putting into one book so much valuable material for reference

His discussion of the nutritive value and place in the diet of the different types of food is as one would expect of the author of "Food and Nutrition" a particularly strong clear and authoritative interpretation of the recent advances in the study of nutrition

The reviewer feels that the value of the material as a text book would be improved by placing the chapter on Food Legislation in the appendix along with the Rules and Regulations for the Enforcement of the Food and Drugs Act She also suggests that Chapter IX should precede Chapter VIII or at least that the general statements concerning vegetables should be given before the discussion of any part of the group It seems a little strange with the author's leaning toward chemistry that he does not suggest a chemical classification of vegetables in addition to the others given One wonders why the discussion of the starches was not followed directly by that of the sugars instead of placing fats and oils between However the arrangement of material concerning which there is a great difference of opinion is a very minor matter in comparison with the advantage of having at hand for reference so admirable a book
ISABEL BEVIER

UNIVERSITY OF ILLINOIS

The Naturalist's Directory Compiled in 1914
Salem Samuel E. Cassino 1914

This used to be a book useful to all naturalists and there is no good reason why it should not continue to be so if the work were well done and the data edited with reasonable care. The new edition leaves one under the impression that the care taken with it was limited in amount and poor in quality. At page 127 under the general head of the scientific societies of the United States and Canada and under the subhead 'California' are given nine Canadian societies while one other Canadian society is given on page 129 under the subhead 'Canada'. Under the District of Columbia at page 128 only one society is given three others are put under 'Canada' on page 129. The American Association for the Advancement of Science is listed under Massachusetts at page 130. The names and addresses in some of the foreign countries contain an unusually large number of errors. In one of those countries eight names and addresses contain twenty typographic errors. One only needs to look for the names of a few of the scientific societies he knows of or for a dozen or so of the naturalists he knows to find the weakness of the book. It is a great pity. A book such as this one pretends to be and carefully edited would be of great service to naturalists all over the world.

J. C. BRANNEN

FRATERNITY GRADES AT PURDUE UNIVERSITY

I HAVE read with considerable interest the recent article in *SCIENCE* on "Fraternalities and Scholarships at the University of Illinois" by Professor Warnock, since a state of affairs somewhat similar to that he describes exists at Purdue University.

A report made in 1910 by the chairman of the committee on student organizations at Purdue showed a relatively low grade of scholarship in the fraternities. As no decimal grades are used on the registrar's books, the report took into account merely the percentage of A grades in the various groups. This aver-

age for the whole student body including the fraternities was 64 per cent.

The average for the honor fraternities Tau Beta Phi and Alpha Zeta was 85 and for one departmental fraternity Triangle 66 per cent.

All the other fraternities were below normal, ranging from 57 for Acacia to 31 for the solitary sorority. Furthermore, it was shown that although fraternity members constituted but 30 per cent of the total attendance 70 per cent of all students dropped for poor scholarship were fraternity men.

The attention of the fraternities was called to this state of affairs and various efforts were made to stimulate greater interest in scholarship among the members.

The Alford trophy was first competed for in 1912 and won by the Delta Tau Delta. This is a bronze plaque suitably mounted and provided with a silver plate for inscriptions and was offered by Professor T. G. Alford. It is awarded each semester to the Greek letter fraternity making the best record in scholarship, and must be won four times to give permanent possession. It has so far been held by the Delta Tau Delta, Phi Kappa Sigma, Sigma Phi Epsilon and Kappa Sigma.

In 1914 Professor James Troop offered a silver cup for special and honorary fraternities not eligible for the Alford trophy. This was won in the spring of 1914 by Alpha Gamma Rho, an agricultural fraternity.

A somewhat uniform plan for recording the monthly standing of their members was adopted by the various clubs and fraternities and in general much more attention was paid to scholarship than had hitherto been the case.

Besides the standings given out by the registrar's office in connection with the awarding of the trophies, decimal ratings for all fraternity and club members are prepared by the chairman of the committee on student organizations and sent to the respective chapters. Comparisons are made showing whether the members and the chapter as a whole are gaining or losing and attention is called to the standing relative to other organizations.

As far as can be judged from the returns, the various agencies mentioned have stimu-

lated an interest in scholarship among the officers and members of the various organizations, with the result that the average standing of men inside the fraternities compares very favorably with that of non fraternity men

The organizations are arranged in the order corresponding to the grades for the second semester. Several comparisons are interesting.

1 The general average of the fraternities is half a point higher than the general student

Attention is here called to the accompanying chart which shows the scholastic standing of the various clubs and fraternities as compared with the general student average for the first and second semesters of the college year 1918-14. The decimal grades were calculated from the letter grades for each student. At Purdue University A means 85 to 100 per cent, B 70 to 85 per cent, C below 70 (conditioned) and D failure (subject to be repeated). In calculating the decimal grades, A is taken as 90, B as 75, C as 60 and D as 45 per cent.

average. This however, is due to the inclusion of the honor fraternities. Without these the averages would be practically equal.

2 The high standing of the sororities and the remarkable rise of the elder of the two, Phi Lambda Psi, from the bottom of the list in four years' time.

3 The lack of differentiation between departmental fraternities, house clubs and the regular Greek letter fraternities as regards scholarship.

4 The relatively high rank of the Cosmo-

politan Club or Corda Fratres considering that it is largely made up of foreigners more or less unfamiliar with our language and our educational methods

Observation of the grades of various individuals and classes has shown that carelessness in pledging is largely responsible for fluctuations in scholarship. A sudden drop in the standing of an organization is usually due to the entrance of an inferior group of freshmen. Sometimes this one class will handicap the whole organization for several years. Other wise the weeding out of incompetents and close supervision of the weak will remove the difficulty in a year's time. There is at the present time a general disposition on the part of the fraternities not to initiate pledges who are conditioned in any way.

A comparison of the class averages of fraternity men is made in the accompanying table.

<i>College Year 1913-1914</i>				
	Senior	Junior	Sophomore	Freshman
First semester	82.5	80.6	80.6	80
Second semester	83	81.1	80.5	79.7

The gradual elimination of the unfit and the survival of the fit is pretty closely shown by these figures.

When we come to study the records of individual organizations for a period of years, we find some interesting facts.

In 1912 the Sigma Pi, a new chapter, was at or near the bottom of the list with a grade of 76.3. Six months of determined work on the part of its officers and members put it tenth in a list of twenty-eight organizations with a grade of 81.9 and second in a list of thirteen Greek letter fraternities.

On the other hand one of the house clubs through carelessness in its pledges and its house rules has dropped in one year from the fourth to the twenty-fourth place.

One of the fraternities, Sigma Nu, has remained consistently near the bottom of the list, never rising higher than No. 21 and being now No. 27 in a list of twenty-eight.

One of the other fraternities, Beta Theta Pi, has remained just as consistently in the upper middle section, its grade never falling below 80.4 and never rising above 81.5.

Of the four Greek letter fraternities winning the Alford trophy in successive semesters the present rank in a list of thirteen is as follows:

Delta Tau Delta	4
Phi Kappa Sigma	9
Sigma Phi Epsilon	8
Kappa Sigma	1

a list which shows the rather violent fluctuations in rank occurring in a short period of time.

A comparison of the various classes or groups of organizations gives the following average grades for the two college years 1912-13 and 1913-14:

(2) Honorary fraternities	86.8
(3) Departmental	82.7
(13) Greek letter	80.1
(2) Sororities	83.5
(4) Special fraternities	80.5
(4) House clubs	81.2

The fraternity or social club suffers from certain tendencies which are more or less unavoidable in this kind of community life.

First there is the disposition to choose pledges hastily and from considerations apart from the real value of the man. On the score of relationship of social standing or of athletic prowess many candidates are chosen in haste and repented of at leisure.

Second there is the tendency to relax the house rules and to permit more loafing, singing, smoking and card playing than is for the best interests of the organization. The more or less luxurious living and the feeling of boon companionship are too alluring for weak-kneed students who have not been used to such opportunities. This is a matter which any chapter can easily control if it wishes.

Third, there is the fact that fraternity men as a rule engage in student activities to a greater extent than do the non-fraternity men.

In 1911 the writer addressed letters to the deans of several neighboring universities, ask-

ing information as to the relative standing of fraternity men reasons for any deficiencies which might exist and possible advantages to offset such deficiencies. Replies were received from the universities of Illinois Iowa Michigan Wisconsin and Minnesota. Although there was naturally considerable variety of opinion on the whole the replies were favorable to the fraternities assuming that the latter were normal and were properly governed.

The grade of scholarship was generally admitted to be somewhat lower but on the other hand it was conceded by most of the writers that fraternity men took a more active part in student affairs.

The accompanying table shows the conditions existing at Purdue and at Wisconsin in 1911 and it is possible that the relative values would be much the same to day.

Fraternity Men in Student Activities 1911 1912

Activities	Purdue			Wisconsin		
	Total	Frat.	% Frat.	Total	Frat.	% Frat.
Athletics (varsity)	38	15	39.5	83	39	47
Publications (editors)	24	7	29.2	95	56	59
Music and drama	18	9	50	89	62	69.7
Class officers	15	7	46.6	48	24	50
Honorary societies	46	8	17.4	42	7	16.7
Totals	141	46	32.6 av	357	188	52.7 av
Per cent of students in university			23.9			27.3

It will be noted that in all branches of activity but one the percentages of fraternity membership are higher than the percentage of total membership in the university.

In honorary societies the fraternity membership is less.

On the whole the fraternity man is one who is content with average rank and is ambitious for athletic social or political rather than scholastic honors. He is a good fellow and probably when he graduates knows more of college life and customs than his barbarian brother.

Men in fraternities and out are much the same intrinsically and what difference there

may be is due rather to environment than to character or ability. O. H. BENJAMIN
PURDUE UNIVERSITY

HOW CAN WE ADVANCE THE SCIENTIFIC CHARACTER OF THE WORK DONE IN THE AMERICAN AGRICULTURAL EXPERIMENT STATIONS?

With the provision of the new Smith Lever Fund for extension and demonstration in agriculture with the increase in the already great number of farm advisers with a thousand agencies for spreading information among the farmers the experiment stations ought to be able at last to find and to occupy their proper field.

That field is research the scientific investigation of questions connected directly or indirectly with agriculture. The demand for men capable of such work has always been greater than the supply of trained and able men. How shall we call men and women to this high service in increased numbers? And how retain them? These are the vital problems which confront the experiment stations there are ways in which the great universities may aid the smaller ones in solving these problems.

Without going into the history of the experiment stations it is sufficient to point out that in the beginning their purpose was not clear even in the minds of most of the early workers they were popular information bureaus in part until they ran short of information. There has been a great deal of repetition and of compilation in their work and, in looking over the earlier bulletins we find little streaks of high grade ore pure investigation the work of men in advance of their time for the most part not appreciated and misunderstood.

The mills of the gods grind slowly, now out of those bulletins published in those earlier years only the ones which were original in thought and method have survived the rest served their temporary purpose and were forgotten.

To day we are beginning to appreciate the value of investigation. In every state university in every meeting of the Association of

American Agricultural Colleges and Experiment Stations we hear the insistent cry for more research, for more men capable of the scientific investigation of problems

Where are we to find men, how are we to train men who have a natural aptitude for research? Under all the conditions prevailing in our state universities, their peculiar type of organization and government, how are we to create and to maintain an atmosphere in which genuinely free minds of high endowments and proven ability may work and grow, following research problems through years to their legitimate conclusions? In short how are we to bring the experiment stations up to the level of the world's best work and thought in science?

The problem is a large one, it touches most vitally and most fundamentally the whole organization of the state university. It is a problem to be studied with the utmost earnestness—are there not ways in which the older universities with established standing may help the newer ones toward a solution?

Few educated men are in any true sense fitted for research and investigation. Much depends upon the training of the man, far more upon the natural gifts and endowments of his mind. It is so easy to endow a college with money—it is so hard to endow it with brains! Men of intelligence, men of rare natural gifts, may be attracted to an experiment station if conditions in the state university to which it is attached are favorable to a man's best development of his best self.

And what, then, are the favoring conditions which make possible in a university a high type of research? A careful canvass of the faculty of one of the larger and older institutions brought out the following opinions:

1 Non interference with the time, the plans, and the work of the research man. This is a negative condition. Why should it be just the one thought of first of all? I think it is because it is the one condition hardest of all to obtain and hardest to maintain in the American state university.

Changes in boards of control and in administrative heads, changes in buildings and

equipment brought about by rapid and poorly coordinated growth, pressure for results from researches which can bear fruit only after prolonged development and in the course of time, a lack of popular appreciation of the out-standing value of laborious, unselfish investigation, that itching for publicity which afflicts many estimable colleges, combinations of teaching or extension or other duties ill-mated with research, vexatious and disturbing financial systems—all these things and many others break into the time and thought of men engaged on research problems oftentimes to the ruin of well planned work.

Under such conditions many a piece of research well conceived and promising, has dwindled like a tree planted in a cellar, until it has died at last and borne no fruit.

Sometimes, too, the pressure for immediate results has led to shallow, popular work, or to a jumping at conclusions akin to quackery. Sometimes legislatures have been led to make great appropriations to such work because of its popular and flashy character, and their money has been wasted, their confidence impaired. Even in hurried America there is no way in which we can force the tree of knowledge to bear fruit before its season.

2 Another important set of conditions allied to the first is that supplied by the type of supervision and direction in vogue. In any research institution the only form of administration or direction which can be successful is the type implied in the word leadership. Above all other things, research, scientific investigation, is a product of the individual mind, or of a group of minds working on related aspects of the same subject. Research is original, original in method and means and in the end sought. If it is not original, then it is not research. No man can tell in advance what are to be his methods and what his results. If he can tell, then his work is not investigation at all, but demonstration, a retracing of the path found by other minds.

The whole trend of thought in college and station work in America indicates that the greatest responsibility of the leaders in administration, their duty and their pleasure,

must be to attract and to hold strong, independent minds, free in thought and fearless in character and then, wholly subordinating the machinery of administration to the ends sought, to lead those minds into the best and highest and most original service of which they are capable. Good administration like good literary style, sinks itself and loses itself in the things said and done and in the work and thought.

In its relation to the whole university as a division or department of the larger whole it is evident that genuine research in the experiment station can progress only where the atmosphere of the university is just, thoughtful, conservative, and in accord with the best traditions of university life and thought.

I have spoken of two fundamental conditions, non interference and leadership, which within the state universities will favor research of a high character. There are other favoring conditions which the universities of high development may establish from without for the benefit of the research spirit in the experiment stations. Let us discuss now two means by which they may exercise a profound influence for good. (1) Why may not the great universities regard the experiment stations as graduate schools? That is what they soon come to mean to the men who do research work in them under happy auspices. When the atmosphere of the university is favorable to research when men are recognized and honored by their colleagues and by the administration because of the high character of the research papers which they have published, then the experiment station becomes a school, a higher university for the members of its staff. In many a university the young man working for his doctor's degree in regular course is not enough alone. He is not forced to draw heavily enough upon his own mental resources to an extent hardly recognized, he may actually develop not his own ideas and lines of thought but those of the teacher whose mind overshadows him. A research problem in an experiment station is a better test of what the man really knows and can do toward the development of that new knowl-

edge which is advancement. In the experiment station the research worker must build his own road into the unknown.

I hope the time may come when the larger and older universities will be glad to place students of exceptional power and maturity and promise in the experiment stations to work upon special problems allied to agriculture in preparation for the doctor's degree. The station should furnish books, laboratory, equipment, money enough to enable the aspiring research student to live in relative comfort. But above all it should supply an atmosphere which would welcome and stimulate and encourage the keenest thought and the bravest effort. Upon the completion of the work to a definite stage it should be published as the station's contribution to knowledge in that field and as the thesis of the candidate for the doctorate. The completion of successful work giving evidence of genuine ability would almost inevitably lead to the employment of the man somewhere in experiment station work. Thus the stations would enrich themselves by adding to their workers young men of demonstrated ability, of high ambition and marked promise, and of preparation under the most favorable conditions. (2) Yet another way in which colleges of high grade and established reputation may do much toward advancing the scientific character of the work done by the experiment stations is by conferring the doctor's degree on men now in station work whose bulletins form a genuine contribution to knowledge.

It is the writer's firm belief that no single agency and no combination of agencies will or can do so much for the elevation of the scientific work of the experiment stations as the interest and the cooperation of the older colleges with established reputations and fine traditions. The stations will strive then by every means in their power to make themselves worthy of such distinguished recognition and support. The treatment of accredited institutions as graduate schools and the prompt recognition of research work by the conferring of the doctor's degree will exert a continual and powerful influence for good upon

the character of the work done in the experiment stations

A DEVICE FOR PROJECTING A SMALL SPOT OF LIGHT SUITABLE FOR EXPLORING PHOTOSENSITIVE AREAS¹

IN experimental work on light reactions the question of the precise location and extent of the photosensitive areas frequently presents itself. If the organism under observation happens to be small, or if minute sensitive elements are scattered in various parts of the integument, the problem has its difficulties. One of the obvious methods of attack is to explore the animal with a spot of light. To be of practical value for this sort of work the light spot must be small, clearly defined and without halo, and it should be possible to direct it with the utmost ease and precision. Various devices have been employed for this purpose none of which has proved entirely satisfactory. The use of a "pinhole" aperture does not give a sharply defined spot of light at a convenient working distance. An elaborate system of collecting and focusing lenses is expensive and is very likely to be cumbersome to handle. After trying various schemes, I found that by inserting a small tungsten bulb into a microscope in place of the ocular and projecting the rays through the objective, a spot of light could be produced which fulfilled the requirements admirably.²

The accompanying figure shows the details of the apparatus. A piece of brass tubing, *P*, is turned to fit into the draw tube of the microscope in place of the ocular, a collar being left on it to prevent it from sliding in too far.

¹From the Museum of Comparative Zoology, Harvard University, and the Anatomical Laboratory of the School of Medicine, Western Reserve University.

²The idea of utilizing the lenses of a microscope was suggested by Dr. Clark of the Physics department of Harvard University.

Into the upper end of this tube is fitted a wooden plug, *X*, bored to take a small screw

FIG 1 A Device for Projecting a Small Spot of Light Suitable for Exploring Photosensitive Areas. *W*, wires from batteries to light, *X*, wooden plug fitted into the tube *P*, and bored to receive socket, *S*, screw socket for light, *L*, 2½ volt tungsten "flash light" bulb, *D*, metal diaphragm with small circular aperture, *K*, cork collars holding diaphragm in place, *G*, diaphragm to cut out reflection from inside of tube, *P*, brass tube fitting into microscope in place of the ocular, *T*, draw tube of microscope, *M*, barrel of microscope, *R*, construction lines indicating formation of the image, *I*, *O*, ocular, *I*, inverted and reduced image of aperture in diaphragm, *D*.

socket.* A two and one half volt tungsten bulb *L*, run by dry cell batteries furnishes the light. Immediately in front of the light a removable metal diaphragm, *D*, is inserted through a slot cut in the side of the tube. The aperture in the diaphragm has, for the sake of convenience and clearness in drawing the figure, been represented much larger than it is desirable to make it. A circular aperture of from one-half a millimeter to a millimeter in diameter is a convenient size. If it is desirable to change the size of the light spot, a set of diaphragms of various sizes can easily be made. A second diaphragm, *G*, made of black cardboard and held in place by being cemented on to a cork collar should be inserted at the lower end of the tube carrying the light. This diaphragm serves to cut out any reflection from the inside of the tube. Its aperture should be about five times the diameter of that in the diaphragm, *D*. A low power objective will be found most serviceable for projecting the light, as it brings it to focus at a distance from the microscope sufficient to allow the experimenter a clear field of vision in directing the spot. It has also the advantage of a greater depth of focus than a high power objective, making it much easier to keep the light spot in sharp focus on a moving animal. The adjustable *A** lenses are of about the right magnifying power and offer the additional advantage of allowing considerable variation in the size of the light spot without a change of diaphragms.

The spot of light produced by this apparatus is, of course, an image of the portion of tungsten filament not cut out by the diaphragm, *D*, reduced as many times as the objective magnifies, and projected at the focal point of the objective. By the use of a moderately high powered lens the spot can be made as small as it is possible to follow with the naked eye, and absolutely without halo if the diaphragms are properly adjusted. It is at the same time very brilliant, and will be found to elicit a marked

response from forms which are at all sensitive to stimulation by light. With it I have forced blow fly larvae to crawl in figure-of-eight loops only five or six centimeters in diameter.

In using the light to follow a moving animal, the barrel of the microscope is removed from the stand and held in the hand like a pencil. One can in this way direct the light with great ease and precision. I have found it so handled, very satisfactory both as a means of exploring for photosensitive areas and as a means of subjecting a limited region to continued stimulation while maintaining the surrounding tissues unstimulated.

BRADLEY M. PATTEN

SCHOOL OF MEDICINE
WESTERN RESERVE UNIVERSITY

THE AMERICAN PHYSIOLOGICAL SOCIETY

THE 27th annual meeting was held in the physiological laboratories of the Washington University Medical School St. Louis Mo., December 28-31, 1914. Fifty-six of the societies' 208 members were present. Five scientific sessions were held, three of these being joint meetings with the other societies of the federation at which the following papers and demonstrations were presented:

W. B. Cannon, C. A. Binger and R. Fitz, "Experimental Hyperthyroidism."

H. R. Bainger and A. L. Tatum, "Studies on Experimental Cretinism."

W. L. Gaines, "The Action of Pituitrin on the Mammary Gland."

George B. Roth, "The Several Factors Involved in the Standardization of Pituitary Extracts."

H. C. Dallwig, A. C. Kolls and A. S. Loevenhart, "The Relation between the Erythrocytes and the Hemoglobin to the Oxygen of the Respired Air."

J. A. E. Eyster and W. J. Meek, "The Path of Conduction for the Cardiac Impulse between the Sino auricular and the Auriculo ventricular Nodes."

C. Brooks and A. B. Luckhardt, "An Experimental and Critical Study of Blood Pressure Methods."

F. C. Becht and M. McGuigan, "Mechanical Factors in the Flow of Cerebrospinal Fluid."

Katherine R. Drinker and C. K. Drinker, "The Effect of Rapid and Progressive Hemorrhage upon the Factors of Coagulation."

* Sockets of a size which fits readily into a microscope and which receive the standard sized flash light bulbs can be obtained of any electrical supply house under the name of "telephone booth sockets."

F C McLean, "On the Concentration of Sodium Chloride in the Serum and its Relation to the Rate of Excretion in Normal and Diabetic Men "

F S Lee and D J Edwards, "The Action of Certain Atmospheric Conditions on Blood Pressure and Heart Rate "

M L Fleisher and Leo Loeb, "The Lytic Action of Tissues on Blood Coagulum "

Ida H Hyde, "The Influence of Light on the Development of Vorticella "

A L Beifeld, H Wheelon and C R Lovelette, "The Effect of Pancreas Extract on Sympathetic Irritability "

B H Schlomovitz, J A E Eyster and W J Meek, "Distribution of Chromotropic Vagus Fibers within the Sino auricular Node "

Ida H Hyde, "The Relation of the Nervous System to a Tunicate Larva "

J R Murlin and B Kramer "The Influence of Sodium Carbonate on the Glycosuria, Hyperglycemia and the Respiratory Metabolism of Depancreatized Dogs "

J J R Macleod, "The Possibility that some of the Hepatic Glycogen may Become converted into Other Substances than Dextrose "

R T Woodyatt, "Narcotics in Phlorhizin Diabetics "

R S Hoskins "Adrenal Deficiency "

H McGuigan, "Hypoglycemia "

J Auer and F L Gates, "Some Effects of Adrenalin when Injected into the Respiratory Tract "

R W Keeton and F C Koch, "The Distribution of Gastrin in the Body "

F T Rogers and L L Hardt, "The Relation of the Digestion Intractions to the Hunger Contractions of the Stomach (Dog, Man) "

F D Zeaman, J Kohn and P E Howe, "Respiration Nitrogen Metabolism of a Man when Ingesting Successively a Non protein and a Normal Diet after a Seven day Fast "

H C Bradley, "Some Studies in Autolysis "

H McGuigan and C L V Hess, "The Diastase of the Blood "

W E Burge, "The Rate of Oxidation of Enzymes and their Corresponding Pro enzymes "

C Voegtlin, "The Harmful Effect of an Exclusive Vegetable Diet "

E L Opie and L B Alford, "Fat Infiltration of the Liver and Kidney Induced by Diet "

V H Mottram, "On the Nature of the Hepatic Fatty Infiltration in Late Pregnancy and Early Lactation "

F B Kingsbury and E T Bell, "The Synthesis of Hippuric Acid in Experimental Tartrate Nephritis in the Rabbit "

C Brooks and A B Luckhardt, "Blood Pressure Methods "

J Erlanger and W E Garrey, "Demonstration of a Point to point Method for Analyzing Induction Shocks by Means of the String Galvanometer "

B M Patten, "A Device for Projecting a Small Spot of Light Suitable for Exploring Photosensitive Areas."

S Amberg and D McClure, "Demonstration of the Effect of Sodiumiodoxybenzoate on Inflammation Caused by Mustard Oil "

Worth Hale "An Arrangement of the Porter Clock to give Three Time Intervals at the Same Time "

F L Gates, "A Portable Respiratory Machine Furnishing Continuous, Intermittent and Remittent Streams of Air "

P A Shaffer, "The Determination of Blood Sugar "

Eight papers were placed on the program to be read by title only. But besides these eight papers, sixteen additional communications placed on the program to be reported were read by title only, owing to the authors being absent from the meeting. It needs scarcely be pointed out that the failure of these 16 papers seriously marred the scientific program. The secretary hopes that this meeting will stand as the high water mark of the disgraceful habit of reporting papers to be read without going to the meeting to present them. In cases of unavoidable absence through sickness, the secretary should be notified, so that readjustments may be made even after the program is in print. And as for those who ask to be placed on the program and then choose to stay away from the meetings the secretary feels that the annual meetings of our society are too important to be made the subject of practical jokes of that type.

Some important changes in the constitution were adopted. The importance of research as the qualification for election to membership in the society was more explicitly emphasized. Voting by mail or proxy was abolished. The management of the *American Journal of Physiology*, owned and published by the society, was entrusted to the council, and the council was enlarged from five to seven members.

In recognition of Dr W T Porter's great service to physiology in founding the *American Jour*

nal of *Physiology* and successfully publishing it for many years, the council was entrusted to arrange for the dedication of a volume of the *Journal* to Dr Porter

The following persons were elected to membership in the society: A Arkin, University of West Virginia, A T Cameron, University of Manitoba, P M Dawson, University of Wisconsin, C M Gruber and E B Krumbhaar, University of Pennsylvania, E N Harvey, Princeton University, H L Higgins, nutrition laboratory of the Carnegie Institution, Jessie L King, Goucher College, F C McLean, Rockefeller Institute, S Morgulis and E L Scott, Columbia University, G B Roth, Hygienic Laboratory, Washington

Officers for 1915

President—W B Cannon

Secretary—C W Greene

Treasurer—J Erlanger

Additional Members of the Council—W H Howell, J R Macleod, W E Garrey, W J Meek

Despite the unusual defaults in the matter of the scientific program, and the presence of only a few members from the Atlantic seaboard, the meeting was a success due largely to the considerate efforts and the generous hospitality of the "local committee." The opportunity to inspect the new laboratories and the hospitals of Washington University Medical School by itself more than compensated for the trip to St Louis. It appears that this school has actually made an advance beyond the 'stone age' of the American universities in general. In material equipment for medical research and teaching, Washington University Medical School is second to none if not superior to all other medical schools in this country.

A J CARLSON
Secretary

UNIVERSITY OF CHICAGO
January, 1915

THE AMERICAN MATHEMATICAL SOCIETY

THE twenty-first annual meeting of the society was held at Columbia University on Friday and Saturday, January 1-2, 1915, the attendance at the four sessions including 95 members, a considerable increase over previous records. The occasion was especially marked by the delivery of President Van Vleck's retiring address, the subject of which was "The rôle of the point set theory in geometry and dynamics."

At the opening session President Van Vleck took

the chair, being relieved by Vice-president L P Eisenhart and at the closing session by the President-elect, Professor E W Brown, and Vice-president Veblen. The following new members were elected: Dr Florence E Allen, University of Wisconsin, Dr Nathan Altshuler, University of Washington, Dr D F Barrow, University of Texas, Dr R B Robbins, Sheffield Scientific School, Mr C H Yeaton, University of Chicago. Fifteen applications for membership in the society were received.

At the annual election the following officers and members of the council were chosen:

President—E W Brown

Vice-presidents—F R Moulton, Oswald Veblen

Secretary—F N Cole

Treasurer—J H Tanner

Librarian—D E Smith

Committee of Publication—F N Cole, Virgil Snyder, J W Young

Members of the Council—G D Birkhoff, O E

Glenn, R G D Richardson, W H Roever

The total membership of the society is now 722, including 72 life members. The treasurer's report shows a balance of \$9,461.75. Sales of publications during the past year amounted to \$1,843.67. The library now contains about 5,100 volumes, exclusive of unbound dissertations.

A most agreeable social concomitant of the annual meeting was the dinner and smoker at the Yale Club on Friday evening. Seventy members took advantage of this opportunity to renew and extend the acquaintance which is one of the valued objects of the society.

The following papers were read at this meeting:

L P Eisenhart "Transformations of surfaces Ω ."

L L Silverman "On the notion of summability for the limit of a function of a continuous variable."

A B Coble "A configuration in finite geometry."

A B Coble "The elliptic norm curve in S_4 ."

J E Rowe "The symmetric and actual form of certain combinants of two binary n -ics."

Arthur Ranum "On the differential geometry of the cyclic (circled) surfaces."

A B Frizell "An enumeration of integral algebraic polynomials."

Dunham Jackson "Expansion problems with irregular boundary conditions."

G M Green "Hypersurfaces and families of curves defined by solutions of a partial differential equation of the second order."

Caroline E Seely "Certain non linear integral equations."

E B Van Vleck, presidential address "The rôle of the point set theory in geometry and dynamics"

W F Osgood "On the division of space of n dimensions by a simple closed surface"

G D Birkhoff "The functions of several variables defined by linear difference and differential equations"

G D Birkhoff "Note on the reducibility of maps"

Virgil Snyder and F R Sharpe "Certain quartic surfaces belonging to infinite discontinuous cremona groups"

II S Vandiver "A property of cyclotomic integers and its relation to Fermat's last theorem"

J L Coolidge "Circular transformations and complex space"

G A Miller "Note on several theorems due to A Capelli"

Edward Kasner "The generalized concept of differential element"

F N Cole "Note on solvable quintics"

G C Evans "Note on the variation of a function depending on all the values of another function"

E V Huntington "A set of postulates for elementary dynamics" (preliminary communication)

F B Moulton "The solution of an infinite system of implicit functions"

C N Haskins "On the roots of the incomplete gamma function"

W C Graustein "On the geodesics and geodesic circles on a developable surface"

D F Barrow "Oriented circles in space"

James MacLay "A transformation of polynomials relatively to the exponents"

J W Alexander II "A method for resolving the singularities of algebraic manifolds"

T H Gronwall "On the summation method of de la Vallée Poussin"

T H Gronwall "An integral equation of the Volterra type"

T H Gronwall "On the distortion in conformal representation"

The winter meeting of the society at Chicago was held on December 28-29. The next regular meeting of the society will be at Columbia University on February 27

F N Cole,
Secretary

SOCIETIES AND ACADEMIES

THE BIOLOGICAL SOCIETY OF WASHINGTON

THE 528th meeting was held in the Assembly hall of the Cosmos Club, October 17, 1914, with President Paul Bartsch in the chair

Resolutions on the death of Theodore N Gill, a founder and former president of the society, were presented

Under the head of Brief Notes, etc., L O Howard presented evidence to show that contrary to report, no birds had been killed in connection with arsenical spraying for the destruction of the gypsy moth in New England. Paul Bartsch reported that English sparrows destroyed many army worms on Washington lawns during the recent invasion by those insects

The regular program followed

A Mouse that Lives in Tree-tops VERNON BAILEY

An account of the history and habits of *Phenacomys longicauda* as observed by the speaker near Eugene, Oregon

Botanical Collecting in the Northwest A S HITCHCOCK

A general account of a trip to the northwestern part of the United States and British Columbia during the past summer in search of grasses

The Present State of Fox Farming NED DEARBORN

Observations made in Prince Edward Island and elsewhere during the past spring

THE 529th meeting was held October 31, President Bartsch presiding

The program consisted of two communications
Pelage Variations of American Moles HARTLEY II T JACKSON

Twenty Years' Experience with Great Apes of Western Africa R L GARNER

Mr Garner's lecture was profusely illustrated with lantern slides and gave much new information relative to African chimpanzees and gorillas

THE 530th meeting was called to order by President Bartsch November 14, 1914

Brief notes were presented by Marcus M Lyon, Jr, L O Howard, A D Hopkins and W H Os good

Three communications were presented

Certain Miocene Fossils WM PALMER

The fossils exhibited were obtained by the speaker at the cliff deposits near Chesapeake Beach, Md. Owing to the scanty material on which Cope's types in the Philadelphia Academy

were based, it was frequently impossible to identify the material collected

Arabic Zoology PAUL B POPENOE

A sketch of the rise of Arabic zoology, with curious extracts from the treatise on the subject "Hayat al Hayawan" by Kamal al Din Muhammad ibn Musa al Damiri, published in the fourteenth century and still the standard authority among Moslems

A National Bird Census WELLS W COOKE

An account of the plans followed and results obtained last June in an attempt by the Biological Survey in cooperation with ornithologists to count the birds that nest within the United States

The 531st meeting was held November 28, with President Bartsch in the chair

Under the heading Brief Notes Dr J W Stiles gave a brief account of experience in sanitation in relation to hookworm disease

Wm Palmer exhibited some interesting fossils from the Miocene deposits near Chesapeake Beach, collected during the past week

Three communications were presented

A Porcupine Skull Showing an Extra Pair of Upper Incisors MARCUS M LYON, JR

The specimen under consideration is believed to be unique It was collected by Dr Abbott in Borneo The extra incisor was regarded as a persistent milk tooth Lantern slide pictures of the skull were shown

Notes on Some Fishes Collected by Dr Mearns in the Colorado River J O SNYDER

The species found in the Colorado basin are distinct from species found elsewhere The faunas of other river basins of the West show the same feature From evidence shown by general speaker concluded that communication between the basins must have been at a very remote period and by way of the head waters He exhibited specimens taken by Dr Mearns

Notes on Some Birds Observed on the Florida Keys in April, 1914

Observations as related to birds seen during an 8 days' cruise among the Florida Keys last April Most of the stay was at Bird Key Lantern slides were used in illustration

THE 532d regular and 35th annual meeting was held December 12, 1914, President Bartsch presiding The annual reports of officers were received The election of officers for 1915 resulted in the following selections

President—Paul Bartsch

Vice presidents—A D Hopkins, W P Hay, J N Rose, Mary J Rathbun

Recording Secretary—Marius M Lyon, Jr

Corresponding Secretary—W L McAtee

Treasurer—Wells W Cooke

Members of Council—Hugh M Smith, Vernon Bailey, Wm Palmer, N Hollister, J W Gidley

D E LANTZ,

Recording Secretary

THE SCIENCE CLUB OF THE UNIVERSITY OF WISCONSIN

The first meeting of the Science Club of the University of Wisconsin was held at the University Club on January 6, 1915

Professor Daniel W Mead, of the department of hydraulic and sanitary engineering of the University of Wisconsin, gave an account of his visit to China last summer where he and Col W L Siebert and Arthur P Davis, chief of the U S Reclamation Service were called by the Chinese government for consultation upon the problem of preventing floods and reclaiming for agriculture lands now inundated by rivers and the sea

The lecture was devoted mainly to an account of the engineering works of the Chinese These are for the most part ancient, as there has not only been no new construction but the ancient works have been allowed to fall into disrepair

The most notable works of the Chinese are their bridges, walls for defense and dikes, levees and canals for navigation, irrigation and protection against floods These are characterized by enormous expenditure of labor and material in their construction Evidences of the ignorance and superstition of the constructors abound, and in many cases reduce the effectiveness of the works very materially

The existing government in China recognizes the need for extensive reconstruction and extension of works for defense against the floods that destroy millions of the people each century The visiting engineers were received with greatest respect and were afforded every facility for their work by representatives of the national and local governments

The lecture was illustrated with many beautiful lantern slides prepared and colored by Japanese artists from photographs made by Professor Mead during his trip

The meeting was preceded by a dinner at the University Club by members of the Science Club, their wives and guests

ERIC R MILLER,

Secretary

INTRODUCTORY ADDRESS

IN calling this meeting to order I wish first to say a few words about the services performed by the committee on organization—and I am sure none of them will think it invidious if I refer particularly to the work of the secretary Professor Lovejoy who has borne the heat and labor of the day more than any one else. All of its members are busy men and the work they have done is a labor of love. It is but fair to them that it should be known to all that their labors continued for over a year have been singularly free from a disposition on the part of any one to push a particular scheme or file a particular hobby. If any one perchance has come here to-day with a fear that something is to be sprung upon the meeting or that the committee has—as the saying goes—something up its sleeve, pray let him disabuse himself of the idea. The committee has tried to do nothing more than had to be done to bring together a representative body without reference to factions or sections to get matters into shape to facilitate discussion and economize time.

Doubtless we have made mistakes. But they are only such as are incident to getting a large enterprise under way especially considering the lack of authoritative precedents to follow and the lack of such clerical and other machinery as the organization itself will bring into being. The committee found itself between the Scylla of doing nothing definite and the Charybdis of doing so much as to forestall action that

ought to be taken only by the organization itself. So it thought its main effort should be to collect representative opinions and to secure the adhesion of a body of men large enough to represent different types of institutions, different lines of work and different sections of the country. Each member of the committee was asked to prepare two lists of names: one of men of full professorial rank in his own institution and the other of men (of like grade) in his own subject irrespective of institutional connection. Then these two lists were combined so as to include names found on either. To simplify the work, invitations were not sent to men in institutions represented by less than five names.

You will readily see that there was no available way for standardizing the basis of selection employed by the more than thirty men on the committee. Hence it is not only probable that there are omissions of teachers who should have been asked but that there is inequity of distribution among different institutions and branches of learning. But I am sure that there is no inequality which can not readily be straightened out in the workings of the association itself. It should also be stated that the draft of a constitution to be submitted has not for lack of time and because of the wide geographical distribution of the men on the committee been authorized by the committee as a whole. This is hardly to be regretted for it reserves for each member complete freedom of action and emphasizes the point that the chief object of its preparation is not to supply an ideal or final draft but a definite basis for discussions to bring out and register the will of the meeting. At the same time it should be said that the draft does not represent so much the wishes of the members of the subcommittee personally as the preponderant drift of the opinions ex-

pressed in letters in reply to the circulars sent out.

As much as this I should probably have felt like saying in any case. But the committee has asked me also to speak upon the reasons for calling this assembly together. What is the proposed association for? Any proposal to increase the existing number of associations, meetings, etc., assumes a serious responsibility. The burden of proof is upon it.

We are in a period of intense and rapid growth of higher education. No minister of public education controls the growth; there is no common educational legislature to discuss and decide its proper course; no single tribunal to which moot questions may be brought. There are not even long established traditions to guide the expansive growth. Whatever unity is found is due to the pressure of like needs, the influence of institutional imitation and rivalry and to informal exchange of experience and ideas. These methods have accomplished great things. Within almost a single generation our higher education has undergone a transformation amounting to a revolution. And I venture to say that in spite of the deficiencies we so freely deplore, no country has at any time accomplished more in the same number of years.

But have we not come to a time when more can be achieved by taking thought together? In the future as in the past progress will depend upon local efforts in response to local needs and resources. We have the advantages as well as the disadvantages of the lack of the European system of centralized control. So much the more reason for the existence of a central body of teachers which lacking official and administrative power will express the opinion of the profession where it exists and foster its formation where it does not exist. I am a great believer in the power

of public opinion. In this country nothing stands against it. But to act it must exist. To act wisely it must be intelligently formed. To be intelligently formed it must be the result of deliberate inquiry and discussion. It can not be developed in corners here and there; it can not be the voice of a few, however wise. It must be formed democratically, that is cooperatively. All interests, however humble, must be heard; inquiry and conference must glean all the experiences available; decision must be based upon mutual consultation.

The need of a voluntary organization is the greater because of certain facts in the history of the American university. The rapid growth already referred to has occurred under a machinery designed for very different conditions. We are doing our educational work under methods of control developed decades ago, before any thing like the existing type of university was thought of. Our official methods of fixing fundamental educational policy as well as of recruiting, appointing, promoting and dismissing teachers are an inheritance from bygone conditions. Their lack of adaptation to the present situation is due not to sinister intent, but to the fact that they are a heritage from colonial days and provincial habits. The wonder is not that there is so much restlessness and friction, but that there is not more. A system inherently absurd in the present situation has been made workable because of the reasonableness and good will of the governors on one side and even more of the governed on the other.

All the more need then of ascertaining precipitating in discussions and crystallizing in conclusions the educational experiences and aspirations of the scholars of the country. I confess myself unable to understand the temper of mind which anticipates the danger of what some term trades union

ism or of interference with constituted administrative authorities as a result of the formation of this organization. As to the latter, I know of few teachers who wish additional administrative work; most would be glad of relief from duties that do not seem exactly significant and that are time-consuming. But it is not expedient in view of the trust committed to us to maintain a state of affairs which makes difficult or impossible among college teachers the formation and expression of a public opinion based on ascertained facts. I can not imagine that existing authorities will not welcome the results of inquiries and discussion carried on by a truly representative body of teachers. To think otherwise is to dishonor both ourselves and them. The only thing which is undignified and intolerable is that teachers individually or collectively should indulge in carping criticism of boards of trustees when they have not thought it worth while to cultivate an enlightened educational policy among themselves nor found the means for making themselves heard. If we do not like the present situation we have nobody but ourselves to blame.

Let me add that I can think of nothing so well calculated to lift discussions of educational defects and possibilities from the plane of emotion to that of intelligence as the existence of a truly representative body of professors. The best way to put educational principles where they belong—in the atmosphere of scientific discussion—is to disentangle them from the local circumstances with which they so easily get bound up in a given institution. So to free them is already to have taken a step in their generalization. The very moment we free our perplexities from their local setting they perforce fall into a truer perspective. Passion, prejudice, partisanship, cowardice and truculence alike tend to be eliminated.

and impartial and objective considerations to come to the front. The very existence of a recognized free forum of discussion with one's fellows gathered from all parts of the country will make for sanity and steadiness quite as much as for courage.

The fear that a "trade unionism" of spirit will be cultivated is ungrounded. I have great respect for trade unions and what they accomplish. Many of the questions which have been suggested for consideration by this body have their economic aspect. Since economic conditions seriously affect the efficiency and scope of our educational work, such topics are surely legitimate ones for inquiry and report. But the term "trade unionism" has been used to suggest a fear that we are likely to subordinate our proper educational activities to selfish and monetary considerations. I have never heard any one suggest such a danger for the American Bar Association or the American Medical Association. Pray, are the aims of college teachers less elevated? Or is it that our position is so much less assured that any organized association must take on such a color? Are we animated by a narrower or more sordid spirit? Is there anything in the history of our body which indicates materialism of spirit or indeed anything but an idealism which lends itself to being imposed upon rather than to propaganda in behalf of narrow trade interests? Ladies and gentlemen, I resent such manifestations. I can not believe that we are fallen so low that association for the purpose of careful investigation and discussion of common educational interests can be interpreted by any right-minded person as a rebellious and mercenary organization. If we have so fallen, something immensely more radical than the formation of this organization is the indicated remedy.

A word upon the subject of the relation of the association to academic freedom

may be in place especially as it has been mistakenly stated in the public prints that this matter is the chief cause of the formation of this organization. I do not know any college teacher who does not believe that cases of infringement may arise. I do not know any who does not hold that such infringement when it occurs is an attack upon the integrity of our calling. But such cases are too rare to demand or even suggest the formation of an association like this. Existing learned societies are already disposed to deal with cases of infringement as they may come to light, and in my opinion it is a matter of detail rather than of principle whether they should be dealt with by such special bodies or by a more inclusive body like this. In any case I am confident that the topic can not be more than an incident of the activities of the association in developing professional standards and standards which will be quite as scrupulous regarding the obligations imposed by freedom as jealous for the freedom itself. The existence of publicly recognized and enforced standards would tend almost automatically to protect the freedom of the individual and to secure institutions against its abuse.

In conclusion let me say that proposing such an association as this is to my mind but proposing to apply to our common calling the standards and ideals to which we have been trained, each in his special line of work. In his own branch, each of us recognizes how little he can do by himself, how dependent his efforts are upon cooperation and reinforcement by the work of a multitude of others. Let us cultivate a like social sense of the wide educational interests we have in common, of our dependence upon one another as institutions and as teachers. In his own specialty each of us recognizes the need of careful study of facts before coming to a conclu-

sion Shall we not require of ourselves a similar scientific spirit as we try to settle educational questions? A more intense consciousness of our common vocation, our common object and common destiny, and a more resolute desire to apply the methods of science, methods of inquiry and publicity, to our work in teaching—these are the things which call for the existence of organized effort Surely we shall have the judgment, the courage and the self sacrifice commensurate with reverence for our calling which is none other than the discovery and diffusion of truth No one has any illusions about what can be immediately accomplished Let us therefore arm ourselves with patience and endurance in view of remoter issues No one underestimates the practical difficulties in our way But arming ourselves with the good will and mutual confidence our profession exacts of us we shall go forward and overcome them

JOHN DEWEY

ORGANIZATION OF THE AMERICAN ASSOCIATION OF UNIVERSITY PROFESSORS

THE meeting called for the purpose of organizing this association was held in the auditorium of the Chemists' Club, New York City, on the afternoon and evening of Friday, January 1 and the morning of Saturday, January 2, 1915 Over 250 were in attendance in the course of the three sessions Professor John Dewey, of Columbia University, called the meeting to order and delivered an introductory address upon the purpose and possibilities of such an association, as conceived by the committee on organization, of which he had served as chairman Nominations for the chairmanship of the meeting being called for, Professor Dewey was nominated and elected permanent chairman, and Professor Over-

street, of the College of the City of New York, recording secretary Addresses in support of a motion to proceed to the organization of the association were made by Professors Guthe of Michigan, Thilly of Cornell West of Princeton, Howard of Nebraska, and a letter from Professor Gildersleeve of Johns Hopkins was read The motion was unanimously carried

The consideration of the draft of a constitution submitted by the committee on organization was then begun This took up most of the afternoon and evening and a part of the morning session In order that the alternative plans of organization might receive full discussion, the meeting, in most cases voted upon the principles involved in the several articles rather than upon the language of the instrument A committee was appointed to draw up the text of a provisional constitution in conformity with the action taken by the meeting this draft to be submitted for ratification at the next annual meeting The decisions of the gathering with respect to the principal features of the plan of organization were as follows

1 *Name*—After the consideration of a number of alternatives, it was voted that the name of the society be "The American Association of University Professors"

2 *Eligibility for Membership*—It was voted that any person may be nominated for membership who holds and for ten years has held a teaching or research position in any one, or more than one, American university or college or in a professional school of similar grade, provided, that no person not having teaching or research for his principal occupation, and no administrative officer not giving a substantial amount of instruction, shall be eligible Nominations for membership may be made to the council by any three members of the association, nominations thus made, and ap-

proved by the council, will be voted upon at annual meetings, a two thirds vote being required to elect. For the guidance of the council in acting upon nominations, it was voted, upon motion of Professor Janeway, that "it is the sense of this meeting that the association shall be composed of college and university teachers of recognized scholarship or scientific productivity." It was voted that all persons to whom invitations to attend the first meeting had been sent by the committee on organization may become members of the association by signifying to the secretary their desire to do so, within three months from January 1, provided that they hold positions in institutions of collegiate or university grade and that their duties are not solely administrative.

3 *Officers*—It was voted that the officers of the association shall be a president, a vice president, a secretary, a treasurer, and a council consisting of the foregoing and 30 additional members. The president and vice-president are to be elected by a majority vote for a term of one year, the secretary and treasurer are to hold office for three years. Thirty members of the council are to be elected for the first year, lots being drawn to determine which shall hold office for one, for two and for three years, respectively, at each subsequent annual meeting ten members of the council are to be elected by a plurality vote to hold office for three years. The council has power to arrange the program for the annual meeting and to appoint committees to investigate and report upon subjects germane to the purposes of the association. During the year 1915 the council is authorized to spend such sums out of the funds of the association as may be necessary for the business of the year, and also to defray expenses incurred in the organization of the association.

4 *Local Societies*—The question of the formation of local societies was discussed at some length. Although the sentiment of the meeting was apparently unfavorable to this plan, the council was authorized to take the matter under consideration and to report at the next meeting upon the desirability of the formation of institutional or territorial chapters.

5 *Dues*—The annual dues were fixed at \$2.00.

The greater part of the concluding session was given up to the discussion of topics to be placed upon the program of the association for the ensuing year. The secretary of the committee on organization read a number of interestingly diverse topics suggested in writing by members not present. A paper by Professor Royce of Harvard University on "The Case of Middlebury College and the Carnegie Foundation" was read, proposing as a suitable subject the question of "the limits of standardization" in educational methods and organization and the "standardizing" activities of extra academic corporations. This subject, and the two following, were finally recommended to the council as the topics most suitable for examination by special committees and report during the coming year: methods of appointment and promotion, the manner in which the university teaching profession is at present recruited, with especial reference to the existing system of graduate fellowships and scholarships. Upon Professor Seligman's motion the council was also instructed to attempt to bring about a merging in a new committee of the committees already created by the economic, political science and sociological associations to deal with the subject of academic freedom, the joint committee to be authorized to investigate the subject in behalf of this association and to report at the next annual meeting.

The committee appointed to present nominations for officers for the year 1915 reported, through its chairman, Professor Tatlock, of Michigan, that in the time at its disposal it had not been able to make sufficiently well considered nominations for more than twenty eight places on the council. Professor H C Warren, of Princeton University, who was nominated for the secretaryship, declined the nomination. The following were elected: President John Dewey, Columbia University, education; Vice president J M Coulter, University of Chicago, botany; Treasurer J C Rolfe, University of Pennsylvania, Latin. Members of the council: M Bloomfield, Hopkins, Sanskrit; E Capps, Princeton, Greek; A P Carman, Illinois, physics; A S Cross, Yale, English; G Dock, Washington University, St Louis, medicine; H D Foster, Dartmouth, history; E C Franklin, Stanford, chemistry; C M Gayley, California, English; R G Harrison, Yale, zoology; W H Hobbs, Michigan, geology; A R Hohlfeld, Wisconsin, German; G E Howard, Nebraska, history; A O Lovejoy, Hopkins, philosophy; W T Magruder, Ohio, engineering; J L Meriam, Missouri, education; A A Michelson, Chicago, physics; W B Munro, Harvard, political science; A A Noyes, Massachusetts Institute of Technology, chemistry; E C Pickering, Harvard, astronomy; H C Warren, Princeton, psychology; R Weeks, Columbia, Romance philology; H S White, Vassar, mathematics; J H Wigmore, Northwestern, law; W F Willcox, Cornell, economics. The officers elected were given power to fill the vacancies remaining in the council, and to elect a secretary to serve during the year; it was voted that, pending the election of a secretary, Professor Lovejoy, of Johns Hopkins University, be asked to

continue to discharge the duties of that office.

Votes of thanks were extended to the Chemists' Club for their courtesies, to the Women's University Club for hospitalities to woman members of the profession in attendance at the meeting, and to the officers and members of the committee on organization. The meeting, notable in the history of the American universities and distinguished by the number of eminent scholars attending and by the interest and quality of its discussions, then adjourned.

It is perhaps advisable to put on record at this time the history of the steps, antecedent to this meeting, taken in the organization of the new association. The project was initiated by a communication signed by most of the full professors of the faculty of the Johns Hopkins University, which was sent, in the spring of 1913, to the members of the faculties of nine other universities, inviting the latter to consider the advisability of the formation of such a society, and to send delegates to an informal conference for discussion of the matter. A favorable response was received in all cases, and statements expressing a conviction of the desirability of the creation of some such professional association were drawn up and signed by members of the faculties of nearly all the universities addressed. The proposed conference was held at Baltimore on November 17, 1913; it was attended by 18 delegates from the following universities: Clark, Columbia, Cornell, Harvard, Johns Hopkins, Princeton, Wisconsin and Yale. The chairman of this conference, Professor Bloomfield, was authorized to appoint a committee on organization, representing the principal subjects of study and the principal universities. This committee, under the chairmanship of Professor Dewey, after prolonged discussion, decided that

it would not attempt to define the conditions of eligibility for membership, but that invitations to join in the formal organization of the association should be sent to persons of full professorial rank whose names appeared on the lists of distinguished specialists prepared for the committee in each of the principal subjects, provided that such professors were connected with institutions having five or more names upon these lists. Some 650 of those to whom these invitations were sent have thus far expressed their sympathy with the general purposes formulated in the circular of the committee on organization, and their purpose to adhere to the association.

In accordance with the action above reported, members of the university teaching profession who did not receive invitations to the New York meeting, and who desire to become members of the Association, are asked to signify that desire to any of their colleagues who are already charter members or who may become such during the period allowed for that purpose—the first three months of the present year.

A O LOVEJOY,
Secretary

JOHNS HOPKINS UNIVERSITY

**THE AMERICAN ASSOCIATION FOR THE
ADVANCEMENT OF SCIENCE
SAFETY ENGINEERING¹**

THE address which forms part of the duty each year of your successive chairmen might have for its unvarying subject the newest subdivision of the engineer's field, since each year seems to furnish a new title to our lengthening list of engineering specialists.

One of the late differentiations calls at-

tention to the field of safety engineering, and I bring to your attention some phases of this work. This portion of the field of engineering can not be said to involve any radically new fact or discovery, but to be rather a new grouping of interests as a result of a change of accent among the many industrial factors. In developing any engineering design there is usually a compromise between prime factors which dominate the result and minor factors which receive less accent, so also in industrial life such prime factors as production, cost, profits, expansion, etc., have heretofore received the greater accent while the item of safety of the employee and the public, which has always been a factor in design and in management, has oftentimes been given relatively small weight. There is a rapidly growing feeling that every industry should receive its workers each day in fit condition and should return them to their homes whole and in like fit condition. Strong accent is now being given to this idea, which has resulted in a movement of very considerable momentum, and this change in accent is finding its expression in various legislation, in workmen's compensation acts, in the whole safety movement, including the work of safety engineering. Safety engineering has for its object the elimination of industrial accidents. While the result of such an accident was borne largely by the injured individual, the prevention of accidents remained more or less of a minor factor in industrial problems, but as the industry is required to carry directly a larger share of the burden resulting from accident, the problem has become one of prime importance. Each engineer, mechanical, electrical, civil and mining, is now asked to view his work from a new angle. Guards, guides and protective devices are added where it was perfectly evident these devices should have been before, but it be-

¹ Address of the vice president and chairman of Section D of the American Association for the Advancement of Science, Philadelphia, December 31, 1914.

comes equally evident that this is a most superficial and inadequate treatment of a subject of large proportions. Statistical information is needed as to the kind of injury and the success of preventive methods. Questions arise as to the bearing on the accident problem of nationality, general intelligence, age, temperance, fatigue, housing, lighting and a multiplicity of factors usually considered as outside of the field surveyed by the engineer. The purely engineering phase of this problem has been variously estimated as forming only 10 to 25 per cent of the whole, the problem being more largely one of mental attitude toward the thought of safety on the part of the employee and the whole organization, but the engineer's point of view seems particularly favorable as a point of departure for exploring the whole field and reducing observations to concrete changes in equipment and management. This situation has produced the safety engineer. His work is a new grouping of studies and interests. Beside his purely engineering training he is brought close to the doctor, the chemist, the social worker, the statistician, the works diplomat, the psychologist, the labor organization, legislative limitations and the lawyer. He can no longer measure all his work directly in dollars and he looks first to a column of statistics for evidence of his profits.

In the large industrial organizations the best engineers are thus engaged, under the immediate observation of the administrative head. The excellent results which have been obtained in the reduction of accidents accounts for the enthusiasm shown by industrial safety workers and organizations.

Much of this work requires only special attention to the idea of safety as an important matter, time, patience, careful observation, and the application of obvious rem-

edies which are already in use. The great need at this point is for standardization of method. Considerable sums are expended for protective devices and constructions which are more or less inadequate and which have to be replaced as the art develops. In fire protection and electric installation, it has been found necessary to standardize equipment and a similar need is to be met in safety methods and devices. This can be brought about by preparing standard detailed specifications covering each case or by requiring the use of approved devices, the approval to be issued by some investigative body provided for the purpose. Detailed specifications are apt to be confusing and cumbersome and lack the simplicity of an approval system. The approval of safe devices must, however be done by some body whose decisions will command general support as being the result of careful investigation.

In the mineral industries where the government has provided an investigative bureau for the specific purpose of "increasing safety," the method of granting approval to safe devices after careful investigation is already in operation and has so far provided a list of permissible explosives, approved miners' electric lamps, explosion-proof electric motors switches, etc. Such work must of necessity move slowly, for careful investigation requires both time and money. For the general industrial field other interests are preparing to provide a means of standardizing similar to that brought about by the underwriters' fire insurance regulations.

Much of the more obvious preventative measures can be recognized by members of any and every organization, but there is a class of investigation the need of which has become quite evident which can not be expected of the usual industrial organization. Unsafe conditions are sometimes the result

of obscure physical facts, not so readily apparent, and these cases require long and careful scientific investigation with adequate laboratory facilities. An excellent illustration of this is found in the hazard of coal mine explosions. Such a subject is one studied with difficulty by a single industrial organization and must be referred to some agency specially equipped for investigative work involving engineering, chemistry, physics and a very considerable expenditure of funds. The mining industry presents many such problems such as the ignition of gases and various coal dusts by explosives, by electric sparks and static discharges, and by filaments of broken electric lamps. The permissible limits of vitiation of mine air by natural gases, oxidation of timbers, dusts and fumes and by the use of internal combustion engines for haulage, these require extensive physiological as well as field and laboratory investigation. The deterioration of vital parts of equipment by fatigue shock and corrosion demands laboratory investigation to devise means for proper protection and inspection.

Every industry will present similar safety problems that must be studied more carefully than can be expected of the unaided industrial organization. It is this phase of safety engineering that I wish to specially emphasize.

There are several agencies that can be expected to meet in various degree this need. One of the most promising is that of cooperation between a group of members of an industry and established laboratories, federal, state or educational, which laboratories may be specially fitted by men and equipment for investigating the special problem in hand. By this method the industry furnishes funds for the work while the laboratories furnish oversight, direction and experience in similar inves-

tigations. An investigation of the causes of explosion of grain dust by a group of millers and men interested in coal dust explosions from the Federal Bureau of Mines illustrates this method. Such cooperation between industrial organizations and investigative agencies in safety problems should be greatly extended.

Investigative work in engineering laboratories connected with educational institutions have confined their attention largely to questions of efficiency. The present increased accent on problems of safety should find a similar accent in college engineering courses. Courses in engineering design and construction could without change in hours or relative weight in the whole course give increased emphasis to questions of safety by a careful selection of illustrative problems. Many organizations require that every drawing be "checked for safety" so that each construction has been criticized from this point of view and made to conform to safety standards. The standard screw and nut which has demanded the attention of generations of budding engineers in courses in drawing and design should find a worthy running mate in the standard safety hook or guard railing or belt protection. This change of emphasis should follow also into the engineering laboratories. As an illustration it is essential for safety that gasoline locomotives used in mines or any enclosed space shall produce exhaust gases as free from carbon monoxide as possible. The size of machine that can safely be used under any given mine condition is a function of this carbon monoxide output, and a study of the performance in this regard is of quite as much importance as a study of the capacity or economy of the engine.

State engineering experiment stations in those states which have established such institutions can also be expected to take an

increasing interest in investigations of safety problems peculiar to the industries of each state. Their function has been to investigate fundamental problems relating to the efficient use of the material resources of the state but the change of emphasis brought about by the safety movement will make safety problems of equal moment.

Another agency for the organized study of safety problems is found in the banded casualty insurance companies who are in a peculiarly favorable position to bring an economic pressure to bear upon the industries to install standard adequate safety devices. They propose to offer a reduction in rates where approved safety devices are installed and the underwriters' laboratories are hereafter to test approved safety devices to reduce accident risks as well as devices for reducing fire risks.

The general government is also aiding in safety engineering as it is the province and duty of the Federal Bureau of Mines to conduct investigations with a view to increasing safety in the mining quarrying metallurgical and other mineral industries. This is the first government bureau to be established with the specific object of studying industrial safety in fields other than transportation. The laboratory facilities include an equipped coal mine for the study of mine explosions chemical and physical laboratories and the new buildings about to be commenced include mechanical and electrical laboratories.

These numerous agencies for the careful study of safety problems which lie just behind the field of the self-evident and in the land of the more or less obscure will each contribute something to the motley interests of the safety engineer and will help to eliminate industrial accidents.

U S BUREAU OF MINES

ISOSTASY AND RADIOACTIVITY¹

It is the purpose of this paper to point out some apparent discrepancies between the observations of geodesists on isostasy and the inferences which some radiologists have drawn as to the great age of certain specimens of minerals. It seems well to begin by reviewing the results of isostatic investigations in order to estimate the degree of confidence to which they are entitled and recent advances in radiology demand similar attention.

Correlation of these widely distinct researches is possible because it happens that the emission of heat by a globe whose excess temperature is due solely to radioactivity obeys Fourier's law exactly as does that emitted by a hot but radioactive globe.

Geology as a science is conditioned by the state of the earth's interior and our knowledge of its constitution is now advancing. So late as the foundation of this society in 1889 the Cartesian doctrine of a fluid earth enclosed in a very rigid shell a score or two of miles in thickness was held by most geologists. We now know that the globe is solid and on the whole of great rigidity and probably divisible into at least four distinct shells each more rigid than that overlying it that the irregularities in density and structure which are so marked at the surface extend only to a depth of something like a fiftieth of the earth's radius that open cavities or cracks may exist at depths of 20 miles and very possibly down to the level of isostatic compensation. We know too that the earth is radioactive but that the radioactivity is superficial reaching only to a moderate though uncertain level we also know how ever that the earth's heat is not wholly

¹ Abstract of the presidential address before the Geological Society of America December 1914. The full paper is too long for oral delivery and only this abstract was read at the meeting.

of radioactive origin. More information is certainly in store for us for Mr Michelson is now measuring the terrestrial tides in terms of the wave length of light while methods have been developed by which the distribution of density above the level of isostatic compensation can be studied.

Thus the future is full of hope. The rational method of attaining it is to make trial hypotheses and to devise methods of testing them.

Laplace seems to have been the first to grasp the problem of isostasy and in 1818 he maintained that the irregularities of the earth and the causes which disturb its surface extend to but a small depth. I do not find in his memoirs any rigorous proof of this interesting anticipation. Sir John Herschel in 1833 regarded the earth as a yielding mass and considered erosion and deposition as the primum mobile of geology but he did not pursue the subject. Archdeacon Pratt in 1858 first expressed the hypothesis of isostasy in exact terms discussing it mathematically and adducing evidence in its favor from the geodetic survey of India.

As we all know the enormous labor needed to prove the hypothesis from deflections of the vertical was undertaken by Mr John F Hayford. Mr Helmert characterized Hayford's investigation as truly magnificent and called the underlying idea the Pratt-Hayford hypothesis.

Helmert himself devised a method of testing isostasy by observations on the intensity of gravity instead of deflections. His results coincide almost exactly with Hayford's and thus immensely strengthen the theory. At Helmert's suggestion also Mr O. Hecker made many observations on the intensity of gravity at sea. These observations are indeed of inferior accuracy but suffice to prove that isostatic compensation exists beneath the Atlantic and the

Pacific as well as under the United States.

In my opinion the geodetic evidence for isostasy is so manifold and so consistent as to amount to proof. Equilibrium is nearly or quite complete at a depth of between 110 and 140 kilometers the most probable value being near 120 kilometers.

Messrs Hayford and Bowie have also investigated the effect of isostasy on the intensity of gravity in the United States and at selected stations in other parts of the world. This research confirms the existence of isostasy but reveals certain anomalies due either to imperfect compensation some 120 kilometers from the surface or to irregularities in the distribution of density or to both causes.

It is shown in my paper that the largest deflections in the United States and also the largest anomalies could be accounted for by a spherical batholith say of peridotite just buried beneath the surface and having a diameter of $8\frac{1}{2}$ miles. Of course such a batholith would not be considered surprising by geologists. When the existence and abundance of dikes, sills and laccoliths at all accessible levels is considered as well as the probability of their prevalence at all levels above the deepest volcanic foci it appears that heterogeneities in the earth's outer shell are of the order of magnitude needed to account for the gravity anomalies. In short there is much evidence for the conclusion that compensation at the compensation level is very nearly complete.

If so the mass beneath that level must be almost free from strain and can have cooled but little from its primeval temperature.

On the isostatic theory the continents stand out above the bottom of the ocean because of inferior density. This inferiority may be due to higher temperature or to voids such as joints or to both. A third possibility is that it might be due to lithological differences but of that there is no

evidence The sub-continental temperature is comparatively high, for the thermometric gradient shows that at the level of average sea bottom the rocks below the continents have a temperature of about 100° while at the bottom of the sea the thermometer stands near zero As for crushing and jointing, recent experiments in my laboratory show that the volume of a brittle substance such as sulphur, confined in a brass tube, may be increased to the extent of more than six per cent by bending the tube There can be no question that rocks would behave in much the same way under such confinement as that to which deep seated rocks are subject

If the average subcontinental mass down to the compensation level had 3 per cent more voids than the sub oceanic mass this would account for the present mean elevation of the land The same result would follow if the average temperature under the continents were 40° higher than under the ocean Or again the combination of 20° excess of temperature and $1\frac{1}{2}$ per cent excess of voids would account for the continents

If the areas occupied by the continents were originally bounded by the same level surface as the ocean bottoms, but possessed a smaller conductivity, so that they cooled more slowly, then it can be shown that the earth would constitute an imperfect heat engine and that abundant energy would be available for crumpling and crushing of the rocks or for the elevation of the continents

Passing now to the recent developments of radiology, that wonderful branch of physics has very recently developed fresh surprises Rutherford has put forward a nuclear theory of the atom, and van den Broek has shown that the place of an element in the periodic table is determined not by its atomic weight, but by the number of

positive electric charges carried by the nucleus This number of charges is known as the atomic number

Now comes the astounding feature of the subject It has been definitely discovered by Mr Soddy, Sir Ernest Rutherford and others that a single atomic number may be borne by each of several substances which may have different atomic weights and, in the case of radioactive substances, different stabilities, but which are inseparable by ordinary chemical or physical properties They display the same chemical reactions, the same electrochemical behavior, the same spectrum, the same volatility It would appear, according to Rutherford, that the charge on the nucleus is the fundamental constant which determines the physical and chemical properties of the atom Soddy calls the members of a group of elements bearing a single atomic number and occupying therefore a single place in the periodic table "isotopes"

So far as lead is concerned, this revolutionary doctrine has been authoritatively confirmed by T W Richards, who actually finds the atomic weight of lead from uraninite deposits unmistakably lower than that of ordinary lead

The discovery of isotopism sufficiently explains the great discrepancies in the ages of minerals as computed from the uranium-helium ratio and the uranium-lead ratio These ratios also no longer seem adapted to age determinations It seems very possible, however, that the growing knowledge of atomic structure may eventually lead to trustworthy methods of age determination from radioactive phenomena, but in the meantime other methods must be resorted to

If the earth has cooled externally from a high temperature, there must be a certain level at which the temperature of the rock most closely approaches the melting point at the prevailing pressure This may

be called the eutectic level because the additional temperature necessary to fusion would there be a minimum. The question then arises what relation may be supposed to exist between the eutectic level and the level of compensation.

In computing the temperature distribution of a cooling globe which owes a part of its heat to compression or to initial temperature and another part to radioactivity, it is necessary to proceed by trial and error, or to test various assumptions and consider which best fits the facts. I have assumed various ages and computed other conditions corresponding to the actual heat emission of the globe. These other conditions are the depth of the eutectic level, the thickness of the radioactive shell (supposed uniform) and the proportion of the surface gradient due to radioactivity. Two cases are of special interest, the assumed ages being 68 million years and 1,314 million years.

For the lower age the eutectic level is at a depth of 121 kilometers and thus coincides with Hayford's compensation level, the radioactive layer is 258 kilometers thick and radioactivity supplies $\frac{1}{4}$ of the surface gradient or of the earth's heat emission. For an earth 1,314 million years old the eutectic level lies at 300 kilometers, the radioactive layer is 12 kilometers thick and just $\frac{3}{4}$ of the surface gradient is due to radioactivity. In this ancient earth the highest temperature excess due to radioactivity would be found at and below the bottom of the active layer and would amount to only 106° . This is not much in comparison with the temperature of lavas and if this age is the highest worth considering most of the earth's heat must be due to compression.

So great an age as 1,314 million years seems incompatible with other features of the problem. This age implies that a thick shell extending from the compensation level

downward to and beyond the eutectic level, a shell more than 200 kilometers in thickness has cooled after solidification through an average temperature interval of about 600° . Now the geodesists have shown that at the compensation level the strains must be small and I have given reason for believing these strains even smaller than those computed by the geodesists. But I hold it impossible that a layer of rock 200 kilometers thick can cool 600° without setting up large strains.

On the other hand no such difficulty arises in the case of an earth 68 million years old for it is easy to show that only a very small amount of cooling has occurred below its eutectic level. Furthermore, in this case the level of compensation acquires a definite and intelligible physical interpretation. Local fusion would bring about compensation. Where then, should we look for compensation if not at the eutectic level?

In such speculations as this some latitude must be allowed. If as the geodesists suspect it may be the compensation level is as deep as 140 kilometers, and if this is also the eutectic level the earth is 100 million years old the radioactive layer is 474 kilometers thick and 26 per cent of the heat emitted by the earth is of radioactive origin.

It has often been asserted that the discovery of radioactivity indefinitely prolongs the probable age of the earth. To me it seems that the determination of the level of compensation limits both the age of the earth and the amount of radioactive matter in its outer shell.

GEORGE F. BECKER

U S GEOLOGICAL SURVEY

THE CONSTITUTION OF THE ATOM¹

THE subject of the constitution of the atom has come into extreme prominence—great ad-

¹ From the address of the president of the Royal Society, Sir William Crookes, at the anniversary meeting on November 30, and printed in *Nature*.

vances have been made—while much light has been thrown on the ultimate structure of matter. Years ago during the persistent and systematic fractionation of yttrium I explained that I had succeeded in separating the atoms of the so called elements into groups—these groups undoubtedly exhibited different phosphorescent spectra and presumably had different atomic weights—although from the chemical point of view all the groups behaved similarly. I concluded that of the lines and bands of the compound spectrum of an element some are furnished by certain atoms and some by others. I pointed out that this was not likely to be an isolated case—that probably in all so called elements the whole spectrum does not come from all the atoms—that different spectral rays come from different atoms which may be interpreted to mean that there are definite differences in the internal motions of the several groups of which the atoms of a chemical element consist. I ventured to suggest a possible explanation of these facts based on the assumption that acting on the original *protyle* were two forces—one of the character of time accompanied by a lowering of temperature while the other, swinging to and fro like a pendulum and having periodic cycles of ebb and flow rest and activity, would be intimately connected with the force of electricity. I arrived at a presentation of the elements on a lemniscate path which seemed to me to throw some light on the question of their genesis. My researches seemed to show that the persistence of the ultimate character the eternal self existence the fortuitous origin of the chemical elements could no longer be regarded merely as probable.

Apparently bodies exist which possess close upon the same atomic weights and combine in definite proportions with other substances and yet exhibit certain minute differences. For these substances which are capable of being isolated and identified I suggested the name “meta-elements.” Thus there appears to me to be a gradation of molecules of different ranks between the atom and the compound—and these aggregations of atoms in certain circumstances might well pass for simple elementary bodies.

In recent years the old idea of the ultimate atom as a solid particle spherical or otherwise, has slowly almost imperceptibly given way to the more rational conception of a minute planetary or “Saturnian” system of dazzling complexity the conception is many minded, aided here and there by facts that failed to fall in with the old lines of thought. Among the most prominent men through which the new conception has come to light we have Kelvin Stoney Thomson and more recently, headed by Sir Ernest Rutherford a host of vigorous workers in the new science of radioactivity who have built up a conception of atomic physics often “hard to be understood” but that probably is a move in the right direction. Sir Ernest Rutherford supposes the atom to be composed of a nuclear positive charge, exceedingly small compared with the sphere of action of the atom and consisting of a number of unit charges. Surrounding this nucleus is an external shell in which a number of separate negative electrons are distributed. Professor Soddy—whose name is closely associated with that of Sir Ernest Rutherford—is one of the earliest workers in radioactivity and has developed a theory of the chemistry of the radio elements based upon the periodic law and a modified form of lemniscate spiral where the existence of *pseudo-elements* having slightly different atomic weight but identical chemical properties are set out. These “isotopic” elements occupy the same place in the periodic table. He has thus arrived by a totally different path from the one I traveled at the conception of an element having atoms of different weight though chemically identical. The theory has recently received some confirmation by the analyses of the lead that is found in the minerals pitchblende, thorianite etc. In my own laboratory a spectroscopic examination of the lead from Cornwall pitchblende has shown traces of thallium not found in pure assay lead, the unexpected presence of this element may have some bearing on the slightly different atomic weight values recorded for the lead extracted from the radio-minerals.

Without risking a charge of being unduly optimistic I think I may believe we are on the

brink of striking developments in our knowledge of the structure of the elusive atom. Whatever may be the outcome of researches now prosecuted with so much zeal and success, I feel that Addison was speaking with the voice of prophetic truth when, more than a hundred years ago, he said:

Every atom is a standing miracle and endowed with such qualities as could not be impressed upon it by a Power and a Wisdom less than infinite.

SCIENTIFIC NOTES AND NEWS

THE colleagues of Professor Theobald Smith on account of the impending severance of his connection with Harvard University after a service of twenty years to become a member of the Rockefeller Institute of Medical Research, are arranging to present a bas relief of Professor Smith to the medical school and reductions of this will be made and presented to each donor of \$10 or more to the fund. A complimentary dinner will be given to Professor Smith on April 17.

A "GORGAS Medal" to be given yearly in honor of Surgeon General Gorgas has been established by the medical reserve corps, U S Army New York state division. This medal is open to competition to members of the medical corps of the United States army, to medical reserve corps of the army and to members of the medical corps of the organized militia. Officers may submit papers on any subject of a medico military nature.

THE Cornell Society of Civil Engineers held on January 22 in New York City its tenth annual dinner and reunion. The chief guest was Professor Charles D Marx, of Leland Stanford Junior University, who has recently been elected president of the American Society of Civil Engineers.

DR J SCOTT KELLIE, secretary of the Royal Geographical Society, has been awarded the Cullum gold medal of the American Geographical Society.

THE Academy of Natural Sciences of Philadelphia has elected as correspondents Frank Dawson Adams, of Montreal, and Alfred Werner, of Zurich.

DR H E ROBERTSON, of the University of Minnesota, is working in Professor Aschoff's laboratory and clinic at Freiburg, Baden. He reports himself as the only foreign student at present in attendance. The staff of over thirty members has been reduced to five and the number of students from 180 to 40.

THREE physicians of forty who took the recent civil service examination for the position of director of public health education, in the city of New York have been placed on the eligible list and President Henry Moskowitz of the municipal commission is reported to have said that an appointment will be made within a few days by Health Commissioner Goldwater. The eligible candidates are Dr Ira S Wile, Dr Winthrop Talbot and Dr Charles F Bolduan.

THE Fenger Fellowship of \$600 for 1915 has been assigned to Dr George L Mathers, of the resident staff of the Cook County Hospital, Chicago who will carry on work on certain bacteriological problems in pneumonia.

MR GEORGE P VANIER, of Steelton, Pa. has been awarded a certificate of merit by The Franklin Institute Philadelphia, Pa., for his potash bulb. This bulb has been particularly designed for use in the determination in industrial laboratories of the total carbon in iron or steel. Mr Vanier is chief chemist of the Pennsylvania Steel Co., Steelton, Pa. He has also designed zinc tubes and sulphuric acid bulbs for use in connection with the Vanier combustion train for the determination of carbon in steel by the direct combustion method with the electric furnace.

PROFESSOR ARTHUR KEITH, conservator of the museum at the Royal College of Surgeons of England will deliver, during the latter part of March, a course of five lectures on the bearing of recent discoveries on our conception of the evolution and antiquity of man.

COLONEL GEORGE W GOETHALS, who has been appointed Stafford Little lecturer on public affairs at Princeton University for this year, delivered an illustrated lecture on the Panama Canal at Princeton on Wednesday evening, January 27, in Alexander Hall. Owing to the

difficulty in arranging satisfactory dates there will be only one Stafford Little lecture this year instead of the usual two. The lecture will be published by the Princeton University Press in the Stafford Little lecture series, the former volumes in the series being by Grover Cleveland, Joseph H. Choate, Elihu Root and J. G. Schurman.

At the Founder's Day celebration of Clark University on February 1 the speaker will be Dr. R. S. Illie, professor of biology in the university. His subject is 'The Relation of Universities to Investigation.'

On the return from his recent journey west Dr. Ales Hrdlicka of the U. S. National Museum lectured under the auspices of the Archeological Institute on 'The Origin and Antiquity of the American Indian' and on

'Evolution of Man in the Light of Recent Discoveries' at San Diego, Los Angeles, Stanford, Berkeley, San Francisco, Denver, Colorado Springs and Pueblo.

Professor Clara A. Bliss of the department of chemistry of Wells College is on leave of absence for a second year and is studying at Columbia University. Dr. Minnie A. Graham continues as acting professor during Miss Bliss's absence.

Mr. N. C. Nelson of the American Museum of Natural History has returned from several months' archeological field work in New Mexico, where his work was a continuation of that of previous years on the ancient villages of the Tanos south of Santa Fe.

According to daily papers Mr. Burt M. McConnell, who was secretary to Stefansson, the explorer and meteorologist of the Canadian Arctic expedition, is seeking to induce either the United States government or private citizens to send two hydro-aeroplanes into the far north to search for the explorer, who has not been heard from in over a year. Mr. McConnell has returned from Ottawa, where he tried to interest the Naval Service Department in the project. He was told that nothing could be done at this time. The belief in Canada is that Stefansson and his two companions, Anderson and Storkerson, are still alive and doing the work planned.

The city of Philadelphia, acting on the recommendation of The Franklin Institute, Philadelphia, Pa., has awarded the John Scott legacy medal and premium to Dr. Charles Edward Guillaume of Sèvres, France, for his alloy invar. This alloy contains approximately 63.8 per cent iron and 36.2 per cent nickel. It is characterized by possessing an extremely small coefficient of linear expansion, about 0.0000004 per degree Centigrade. Within the limits of atmospheric temperature change its expansion is very exactly proportional to the temperature. It has a modulus of elasticity of about two thirds that of steel, and its hardness is greater than that of hard brass. Invar has found a wide application in metrology and horology. In the former it is particularly useful for secondary standards of length, and in the latter it is employed for pendulum rods, compensating devices for torsion pendulums and balance wheels, correcting the secondary error of temperature in chronometers. Dr. Guillaume has done a large amount of research work in connection with iron-nickel alloys in the course of which he also discovered platinum.

Professor I. F. W. Lindsay Dyer, professor of systematic zoology and taxidermy and curator of birds and mammals in the University of Kansas, died on January 20 at the age of fifty-eight years.

Dr. Dudley Peter Allen, professor of principles of surgery in the medical department of Western Reserve University, Cleveland, for many years, and later emeritus professor, died on January 6 at the age of sixty-two years.

Mr. Thomas Bryant, a distinguished British surgeon, has died at the age of eighty-six years. He retired from the surgical staff of Guy's Hospital in 1888, delivered the Hunterian oration in 1893 and served as president of the Royal College of Surgeons of England from 1896 to 1899.

Surgeon-General William Henry McNamara of the British army died on January 9 at the age of seventy years.

The death is announced at seventy-one years of age of Lieut. Col. D. D. Cunningham,

FRS, formerly professor of physiology in the Medical College, Calcutta

At the meeting of the Entomological Society of France on November 11, the president announced the death at the front of Léon Garreta and Jean Chatanay, two lieutenants of the reserve and members of the society. The president also announced that it has been decided to place a tablet in the library upon which shall be engraved the names of members of the society who have fallen and may fall during the war. He also announced that Captain A. Magdelaine and Messrs J. de Muizon and J. Surcouf, also members, had been wounded but were convalescent, while J. Hervé Bazin was in the hospital with typhoid fever. All of these men are known to American entomologists through their writings.

The following resolution was unanimously adopted at the annual meeting of the Federation of American Societies for Experimental Biology held in St. Louis, on December 28:

WHEREAS, Various of the European nations with which many of our members are related by birth, descent or intellectual friendship are now at war,

Resolved, That we extend to the scientific men within these nations the hope of an early end during peace, which will leave the nations with no permanent cause of rancor towards each other, and which will insure to each the glories of scientific and humanitarian achievement in accordance with its own conception of these ideals.

The Society of American Bacteriologists held its annual meeting in Philadelphia at the Laboratory of Hygiene, University of Pennsylvania, December 29, 30 and 31, 1914. The following officers were elected:

President D. H. Bergey

Vice president John Weinzirl

Secretary Treasurer A. Parker Hitchens.

Council K. F. Kellerman, W. A. Stocking, Jr., R. E. Buchanan and H. J. Conn

Delegate to the American Association for the Advancement of Science M. J. Rosenau

The next regular meeting of the society will be held in Urbana, Illinois. The chairman of the local committee is Professor H. A. Harding. A special meeting of the society will be held in San Francisco during the summer.

The American Microscopical Society at present holds only business meetings. At the recent meeting at Philadelphia the following officers were elected:

President Professor C. A. Kofoid, University of California, Berkeley, California

First Vice president Professor L. D. Swingle, University of Utah, Salt Lake City, Utah

Second Vice president Dr. N. A. Cobb, U. S. Department of Agriculture, Washington, D. C.

Executive Committee Professor J. P. Campbell, University of Georgia; Professor L. E. Griffin, University of Pittsburgh; Professor A. L. Weiman, University of Cincinnati.

Representative on the council of the American Association Drs. H. L. Shantz and R. H. Wolcott.

The report of the custodian showed that the Spencer Tolles research fund closely approaches \$5,000. The income of this fund is now available for aid in research in any microscopic field. Applications should be made to Dr. H. B. Ward, University of Illinois, Urbana, Ill. The membership of the society was shown to have increased steadily for the last four years and now totals 399. The income for the year was \$1,380. The secretary of the society is Professor T. W. Galloway, Millikin University, Decatur, Ill.

The American Folk Lore Society met in Philadelphia on December 30, 1914, in affiliation with the American Anthropological Association and Section H of the American Association for the Advancement of Science. Dr. Pliny Earl Goddard, president of the society, was in the chair. The papers read were as follows:

"The Relation of Folk Lore to Anthropology (presidential address)" by Pliny Earl Goddard
 "The Knowledge of Primitive Man," by A. C. Goldenweiser

"European Tales Among the North American Indians," by Stith Thompson

"The Magic Boat," by Phillips Barry

Officers elected for 1915 are as follows:

President Dr. Pliny Earl Goddard, American Museum of Natural History, New York

First Vice president Professor G. L. Kittredge, Harvard University

Second Vice president Professor J. Walter Fewkes Smithsonian Institution

Editors Professor Franz Boas, Columbia University, Professor Aurelio M. Espinosa, Stanford University

Secretary Dr. Charles Peabody, Cambridge, Mass

Treasurer Mr. E. W. Remick, Boston, Mass

NEARLY all the papers and practically all the discussion at the recent Chicago meeting of the American Philosophical Association centered on practical ethical questions forced to the front by present international political, social and economic conditions. The American Philosophical Association and the Western joined in their meetings, and these two in turn had a joint session with the Political Science Association, the Association of American Law Schools and the American Historical Association on the subject of Democracy and Responsibility. The officers elected by the American Philosophical Association for the ensuing year are *President* Professor A. C. Armstrong of Wesleyan University, *Vice president* Professor W. E. Hocking, of Harvard, *Secretary* *Treasurer*, Professor E. G. Spaulding of Princeton.

THERE has recently been received a notice from Professor Fehr of Geneva, secretary of the International Commission on the Teaching of Mathematics, giving the decision of the central committee to abandon the meeting planned for August, 1915, and also to postpone the preparation of such committee reports as relate to the work of European countries.

THE new radium laboratories of Manchester Infirmary which contain radium of the value of £20,000 raised by public subscription a few months ago have been formally opened by the mayor of the city. A staff of experts will specialize on efforts to apply the radium for the arrest and elimination of cancer. The equipment of the laboratories is second to none in the kingdom and in the 16 rooms allotted to this special work there is ample provision for administering the treatment to patients.

THE board of managers of the New York

Zoological Society held their annual meeting on January 19. It was reported that the Aquarium drew 2,039,707 visitors last year and the park zoological gardens 2,020,433, a substantial increase over 1913. The annual maintenance cost to the city last year was 58 cents a visitor, the appropriations being the same as planned for next year, \$247,000. On January 1 there were at the park 4,353 animals representing 1,179 species and the aquarium 5,109 specimens of 199 species. Animals acquired during the year cost \$25,000. The most notable was a female gorilla brought from Africa by an expedition directed by Mr. R. L. Garner.

THE department of public health of the American Museum of Natural History is at present engaged in the preparation of a special exhibit of military hygiene and sanitation dealing with the health of armies, the hygiene of the individual soldier and the general problems of camp sanitation. A number of new exhibits illustrative of insect borne diseases were added to the department's display during 1914 the most important single exhibit being a model of the flea (carrier of bubonic plague) 1,728,000 times natural size, prepared by Mr. Ignaz Matusch. The history of the bubonic plague in the past is shown by reproductions of a number of early paintings and by a series of maps illustrating the geographic spread of disease during its historic epidemics. A series of photographs of four American army surgeons who discovered the mosquito transmission of yellow fever has been hung near the entrance of the hall.

UNIVERSITY AND EDUCATIONAL NEWS

THE alumni of Stevens Institute of Technology were told at their annual dinner in the Hotel Astor on January 23 that their ten day campaign to raise \$1,360,000 had yielded \$1,164,269 and that an extension of time had been granted in which the remainder might be collected. Dr. Alexander O. Humphreys, president of the institute, made the confident prediction that the whole amount would be raised by the end of this week.

THE Harvard University corporation has set aside \$100,000 to pay Belgian professors who have been driven from their land by the war and may give courses at Harvard University next year

JAMES R MAGFE, '59, has left \$20,000 and a certain further residuary portion of his estate to Haverford College to be added to the general endowment fund

THE Evans Museum and Dental Institute Building which will be occupied by the School of Dentistry of the University of Pennsylvania, will be formally dedicated on February 22

THE Harvard Medical School will hereafter admit as regular students men who have completed two years' work in a college or scientific school of high rank, provided they present certificates (a) that they have stood in the upper third of their class, (b) that one year's course has been taken in physics, biology, general chemistry and organic chemistry, and (c) that they have a reading knowledge of German or French

DISCUSSION AND CORRESPONDENCE

PROFESSOR DALY'S IGNEOUS ROCKS AND
THEIR ORIGIN

TO THE EDITOR OF SCIENCE Permit me to say a few words in regard to the criticism¹ by Mr J P Iddings of a book recently published by Mr R A Daly and entitled "Igneous Rocks and Their Origin" The criticism is of the destructive, not to say the volcanic, type, and one may well imagine Mr Iddings laying down his pen with the deeply felt conviction that a heretical and dangerous book has finally been disposed of

I am afraid Mr Iddings underestimates the strength of his opponent and he probably does not realize what strong influence the Daly theories particularly the stoping theory, have on the younger generation of geologists Mr Iddings thinks that the author of this book suffers from an exuberant if not a disordered, imagination What Mr Daly thinks about the imaginative qualities of his critic has not,

so far, been made public An impartial observer would probably say that the ideal petrologist would be produced could a "syntectic" assimilation be effected of the two

It seems to me that Daly's book is one of the best ever written on the subject of igneous phenomena The principal facts are assembled in the first part of the book illustrated in abundance from the best sources and from occurrences all over the world In the second part the theories and hypotheses are set forth, and illustrated in the same lavish manner from the whole world's literature It is not necessary to agree with all of the author's views, I certainly disagree most heartily with some of them The book is not a "college petrography" to be put into the hands of the beginner, but the advanced student can not fail to be stimulated by these suggestive and brilliant discussions Just to point out one line of argument The theory of gas action, cupolas and "blow piping" is a most interesting and important subject, very largely neglected in most discourses on intrusions

As far as his criticism of the "quantitative classification" is concerned Mr Daly does not stand quite alone There are many of us who fail to see in this elaborate system anything but an admirable card classification of analyses

I venture to suggest, in conclusion, that the unfavorable criticism in SCIENCE does not represent the impartial opinion of petrologists in general

WALDFMAR LINDOREN

BOSTON, MASS

SCIENTIFIC BOOKS

Photo chemistry By S E SHEPPARD, School of Agriculture University of Cambridge Longmans Green and Company 1914 Pp ix + 461

In this new volume of the series of "Text-books of Physical Chemistry," edited by Sir William Ramsay, Dr Sheppard, of Cambridge, presents us with a most painstaking piece of work, and one which for its size is unusually comprehensive The author presents his sub-

¹ SCIENCE, November 13, 1914

ject matter in eleven chapters of which the titles are as follows Historical—The Measurement of Light Quantities—The Energetics of Radiation—Economic and Energetic Relations of Actual Light Sources—The Absorption of Light—Statics and Kinetics of Photo chemical Change—Dynamics of Photo chemical Change—Special Photo chemistry—Radiant Matter and Photo chemical Change—The Genesis of Light in Chemical Change—Organic Photo synthesis

The first four chapters do not carry us much beyond photo physics but give a very satisfactory résumé of those divisions of optical physics which are of primary importance in photo chemistry Beginning with Chapter V the subject matter becomes increasingly chemical in character and the book ends with an excellent account of the more recent investigations into the character of the chlorophyll reactions

To the reviewer the authors method of treatment seems most commendable Such principles as may be considered thoroughly established are treated with scientific conciseness and brevity not in general however without the presentation of sufficient numerical data for illustration In dealing with matters which are still in the formative stage a condition true of so much of photo chemistry the author does not dogmatize but usually leaves the reader with quite the impression that the state of knowledge concerning the subject warrants This makes the book valuable not only for the knowledge which it imparts but also for its stimulus to critical thinking

The book is made up quite directly from the original literature of the subject and is amply provided with citations and references The authors personality shows itself not only in the thoroughness with which the material has been digested and assimilated and later organized for the purpose of clear presentation but also in not infrequent elucidating discussions and in occasional flashes of imaginative explanation The reviewer's impression is that we have here the work of one thoroughly imbued with his subject and at the same time

entirely competent to handle it The book should prove valuable not only to those desiring admittance to the charming mysteries of photo chemistry but should also be welcome as an additional weapon in the armory of the initiated.

S W YOUNG

STANFORD UNIVERSITY

The Hydrogenation of Oils Catalysts and Catalysis and the Generation of Hydrogen
By CARLTON ELLIS New York D Van Nostrand Co 1914 Price \$4.00 net

The book considers very fully the methods of hydrogenation the various catalysts both the base and rare metals and the mechanism of hydrogen addition Besides this the subjects of the analytical constants of the oils and their uses both for culinary purposes and soap making are thoroughly dealt with About one third of the book is devoted to the methods for the generation of hydrogen which is of prime importance these include water gas, decomposition of hydrocarbons steam on heated metals acids on metals the electrolysis of water and the safety devices for handling the gas

A feature of the book is the very complete citation of references and patents from the three principal languages

The volume satisfactorily fills a decided want and may be unreservedly recommended to all interested

A H GILL

A Text book of Medical Entomology By WALTER SCOTT PATTON M B (Edin), I M S King Institute of Preventive Medicine Madras and FRANCIS WILLIAM CRAIG M D (Edin) I M S Central Research Institute Kasauli Punjab Christian Literature Society for India London Madras and Calcutta 1913 Pp xxxiv + 768 84 pls £1 1-0

The protozoologist parasitologist or physician who has occasion to deal with the arthropodan carriers of diseases produced by bacteria, Protozoa or nematodes has long been hampered in his investigation by reason of

the relative inaccessibility of the pertinent entomological literature. It is widely scattered in expensive journals of restricted circulation often out of print and very generally not to be had under any circumstances by workers on the firing line of research in the tropics far from libraries. To investigate even the commonest insects such as the house fly, the flea, the louse and the bed bug requires an extensive and expensive library and when this is in hand the entomological novice is all too often nonplussed by the exasperating hiatuses in the information available and still more by the perplexing confusion in technical anatomical nomenclature as for example in the case of the wing veins of insects, and the parts of the thorax of the house fly. Text-books of entomology contain so little of the data essential to the workers in the fields of preventive and comparative medicine that they are practically useless as aids to the inquiring specialist.

This need (which has grown so rapidly in recent years) of an adequate text book in this field bids fair to be very adequately met by Drs Patton and Cragg's "Medical Entomology". The book is itself a product of this need of this frontier of science for it has been produced by two experienced workers in the Indian Medical Service and has been adequately illustrated and well printed in India.

The reader might perhaps infer from this that the book was a provincial one adapted to the locality of its origin. The insects with which it deals are most of them cosmopolitan, often to genera, and in many important instances as in the fly, flea, louse and some mosquitoes, even to species. But far more important than the objective cosmopolitanism of the work is the broad and comprehensive outlook of the authors and their very sincere and painstaking effort manifest throughout the work to make the book widely useful, soundly accurate, fairly complete, and wisely proportioned. The result is a treatise which will be indispensable to every worker in medical entomology in tropical or temperate lands.

It treats *in extenso* of insect morphology, drawing its material from those genera and

species of medical importance with especial emphasis upon the Diptera. The classification is likewise carefully worked out with detailed treatment where significant, as for example in the case of those most concerned or under suspicion as carriers, such as the Psychodidae *Tabanus*, *Anopheles*, *Stegomyia*, Culex larva, *Musca* and *Glossina*. The life-history, breeding habits, seasonal prevalence, relation to environmental factors and the methods of collecting, rearing and feeding are carefully noted and the pitfalls which await the inexperienced worker are very frequently pointed out. One chapter is devoted to the fleas, one to the Rhynchota or bugs and another which will be especially welcomed, to the Anoplura or lice. In every case the treatment is not restricted to known carriers, but others which are equally wont to fall into the hands of inquiring specialists are included. The known relations to disease are cited as in the many species of *Anopheles* and the types of parasites known to occur in the insect, their location in the body and in the life history, and the modes of infection, in fact the full medical bionomics of host and parasite are all briefly summarized.

The Acari and Pentastomida receive a full discussion, especially the first named group and there is a brief and rather inadequate section (the last) devoted to *Cyclops* in relation to the guinea worm. A closing chapter deals with those special forms of technique in the preparation of Arthropodan tissues and organs for microscopical examination which are supplementary to the usual lines of instruction given in medical education.

Brief bibliographies of the most important papers, synoptic keys of large groups such as *Anopheles* by locality for example of the Philippine Islands, simple but clear and adequate and fairly abundant illustrations, a full index and a well organized and clearly written text all combine to render very useful an excellent scientific treatise. The defects due to inadequate editing in matters of correlation of references and in elimination of some obscurities of statement, to incomplete or inconveniently located explanations of figures,

and to some important omissions in bibliographies may well be corrected in a later edition

SPECIAL ARTICLES

THE SIMPLEST CONSTITUENTS REQUIRED FOR GROWTH AND THE COMPLETION OF THE LIFE CYCLE IN AN INSECT (DROSOPHILA)

THE green plants are able to build up all the complicated proteins, polysaccharides and fats of their tissues from nitrates phosphates and sulphates on the one hand, and from CO_2 on the other. Those microorganisms which can not form sugar or starch from CO_2 must be offered a more complicated compound than CO_2 for the synthesis of their carbohydrates. They may be able, however, to form all their proteins from an ammonium salt or a single amino acid. This astonishing synthetic power is in sharp contrast to the behavior of mammals which according to Osborne and Mendel, can not grow unless one or more proteins are offered to them for the reason that they lack the power of manufacturing the majority of amino acids required for the building up of the proteins of their body.

Recent experimenters have pointed out that in addition to the chemically well-defined constituents of food other more or less mysterious constituents which only the living body can produce are required for the growth of mammals. Thus Hopkins and Osborne and Mendel have found that certain unknown constituents of milk or butter have a specific effect upon the growth of rats and Allen has found that even a Diatom (*Ihalassiosira*) grows incomparably better if one to four per cent natural sea water is added to the culture medium.

It seemed of interest to find out which substances are required for the growth and the completion of the life cycle of such highly specialized animals as insects. The banana fly (*Drosophila*) on account of the ease with which it can be raised, served as an object for our investigations.

We wish to report only on one group of the experiments we have made, namely, those referring to the source of nitrogenous compounds

required for the growth and the complete life cycle of these insects. Our culture medium consisted of a solution of the purest cane sugar or grape sugar obtainable, or of both to which certain inorganic salts (Kahlbaum's purest) were added. To this medium was added a very small quantity (about 0.25 gram) of mechanically macerated Schleicher and Schull filter paper (No. 580, "Blue Ribbon") chiefly to keep the flies from drowning and to facilitate the raising of the larvae. Dr. Levene was kind enough to have a nitrogen determination of the filter paper made, which showed that its nitrogen content is 0.008 per cent. In such a solution the flies laid their eggs. The larvae hatched and increased slightly in size during the first days but then their growth stopped although they lived for a considerable time. If however, a small quantity of one or two amino acids *e. g.* alanine or glutamic acid or others or certain ammonium salts, *e. g.*, ammonium tartrate or succinate or a combination of one ammonium salt and one amino acid was added the larvae grew to full size and metamorphosed into pupae and normal flies.

In these experiments everything used was sterilized and in addition the culture media were heated for fifty minutes to about 100°C , but since the flies were not sterile, the development of bacteria was not excluded. The flies were removed as soon as a sufficient number of eggs had been laid. In the majority of experiments no visible fungus formation occurred. When visible fungus growth took place the larvae, as a rule soon died or failed to develop.

If in these experiments the larvae were actually able to manufacture all the complicated nitrogenous compounds of their body from one or two amino acids or from one ammonium salt, without the aid of bacteria, it would indicate a power of synthesis equal to that of bacteria. In this connection it is of importance that the larvae of the banana fly can be raised on their natural vegetable food without bacteria. Thus Guyenot has succeeded in raising aseptically forty successive generations of *Drosophila*, thereby proving that for

the normal nutrition of *Drosophila* no bacterial action is required

It will be our next task to attempt to raise the flies aseptically on our artificial culture media, to decide whether or not in our experiments bacteria performed the work of synthesis for the larvæ

It was natural to raise the question to what extent the nitrogen content of the filter paper contributed to the result. The fact that no larvæ was able to grow on filter paper, water, sugar and salts alone indicates that the nitrogen content of the filter paper played practically no rôle in the nutrition. Moreover, the amount of N contained in the filter paper was negligible compared with the amount of N added in the form of amino acid or ammonium salts. One culture contained as a rule, 200 mg glycocoll or other amino acid, i. e., roughly between 30 and 40 mg of nitrogen. The 250 mg of filter paper added to the culture contained only 0.02 mg of nitrogen. The nitrogen in the filter paper was therefore about between 1/2,000 and 1/1,500 of the total nitrogen in the culture medium. Nevertheless, it is a fact that in liquid cultures without filter paper—in this case glass beads were used to prevent the drowning of the flies—the yield of larvæ was very much smaller than with filter paper. It should also be stated that the larvæ ate little if any of the filter paper. It will be one of the tasks of our further experiments to find out what caused the difference in the two cases.

JACQUES LOEB

THE ROCKEFELLER INSTITUTE
FOR MEDICAL RESEARCH,
NEW YORK

THE BOTANICAL SOCIETY OF AMERICA

The ninth annual meeting of the Botanical Society of America was held in the Medical School of the University of Pennsylvania, Philadelphia, Pa. December 29-31, 1914. The following officers were elected for the ensuing year:

President—John M. Coulter
Vice president—R. A. Harper
Treasurer—Arthur Hollick
Councilor—W. F. Ganong

The resignation of George T. Moore as secretary was accepted and Mr. H. H. Bartlett, of the

Department of Agriculture, elected to fill the unexpired term.

The council for 1915 will consist of above officers and George P. Atkinson and David Fairchild.

The following botanists were elected to membership: Adeline Ames, Department of Agriculture, Washington, D. C.; E. G. Arzberger, Bureau of Plant Industry, Washington, D. C.; Freda M. Bachmann, Milwaukee Downer College, Milwaukee, Wis.; Samuel M. Bain, University of Tennessee, Knoxville, Tenn.; A. L. Bakke, Ames, Iowa; Henry W. Barre, Clemson College, S. C.; H. P. Baras, Oregon Agric. Coll., Corvallis, Oregon; R. Kent Beattie, Bureau of Plant Industry, Washington, D. C.; Albert T. Bell, University of Louisiana, Baton Rouge, La.; H. M. Benedict, University of Cincinnati, Cincinnati, O.; R. C. Benedict, 2303 New Kirk Ave., Brooklyn, New York; Charles Brooks, Bureau of Plant Industry, Washington, D. C.; E. P. Bicknell, 30 Pine St., New York City; Guy R. Buseby, Brooklyn Botanic Garden, Brooklyn, N. Y.; Harry P. Brown, 219 Linden Ave., Ithaca, N. Y.; Stewardson Brown, 20 East Penn St., Philadelphia, Penna.; Edward Sandford Burgess, Hunter College, New York City; Gertrude S. Burlingham, 558 Lafayette Ave., Brooklyn, N. Y.; George H. Chapman, Mass. Agric. College, Amherst, Mass.; C. Harvey Crabb, Va. Agr. Exp. Sta., Blacksburg, Va.; Richard O. Cromwell, North Carolina Agric. Exp. Sta., West Raleigh, N. C.; Gilbert Cameron Cunningham, Burlington, Vt.; Charles C. Deam, Bluffton, Indiana; W. W. Eggleston, Dept. of Agriculture, Washington, D. C.; John H. On the afternoon of December 30 a symposium on "The Genetic Relationship of Organisms" was held. The subject was considered under the following heads

1 "Morphology as a Factor in Determining Genetic Relationships" Dr J M Greenman, Missouri Botanical Garden

Discussion led by Dr A S Hitchcock, Department of Agriculture

2 "The Genetic Relationship of *Paramecia*" Dr F D Kern, Pennsylvania State College

Discussion led by Dr C L Shear, U S Department of Agriculture

3 "The Experimental Study of Genetic Relationship" Dr H H Bartlett, U S Department of Agriculture

Discussion led by Dr B M Davis, University of Pennsylvania

The address of retiring President D H Campbell on "Present Tendencies in Botanical Work in America," was delivered at the dinner for all botanists on the evening of December 30

An Endophytic Endodermal Fungus in Solanum tuberosum E MEAD WILCOX, GEO K K LINK AND FLORENCE A MCCORMICK

A preliminary account of an endophytic fungus in *Solanum tuberosum*. This fungus is found throughout the whole plant but is confined to the endodermis, and, in the usual vegetative propagation of the potato proceeds from the tuber through the shoots to the daughter tubers. A discussion of its possible relation to tuberization is included

Report on Cultures with Foliaceous Species of Peridermium on Pine Made in 1914 GEORGE G HEDGECOCK AND WM H LONG

This paper gives a summary of an extensive series of experiments with six of the foliicolous species of *Peridermium* on pines of the United States, viz *Peridermium accolum* Underw & Farle *P. carneum* (Bosc.) Seym & Earle *P. delcatulum* Arth & Kern, *P. inconspicuum* Long, *P. intermedium* Arth & Kern, and *P. montanum* Arth & Kern. A total of 712 inoculations were made with these species and the species of *Coleosporium* of which these *Peridermia* are alternate forms. The results of the experiments are revolutionary, since they indicate that at least four of these species of *Peridermium* and the related species of *Coleosporium* belong to one polymorphic species, and that the transfer from one herbaceous host to another is accomplished through the asexual forms in the pines

Origin and Development of the Lamellae in Coprinus comatus atramentarius and mucaceus GEORGE F ATKINSON

The origin and development of the lamellae is described and compared with the two types already known in *Agaricus* and *Amanitopsis*

The Specific Identity of Phallus impudens and Dictyophora duplicata GEO F ATKINSON

The only differential character between these two species is the possession of an indusium by the latter. The indusium varies in strength of development. Sometimes it is strongly developed, sometimes very weakly so, sometimes wanting or only a fundament of it in the embryonic stage

The Relationship of Endothia parasitica and Related Species to the Tannin Content of the Host Plants MEL T COOK AND GUY WEST WILSON

Endothia parasitica (American and Chinese strains), *E. radialis* and *E. radialis mississippiensis* were grown on a culture medium to which had been added different percentages of commercial tannin and special extracts prepared by Mr. George A. Kerr. Extract "1 X" was soluble in water, "2 X" in water and alcohol, both were tannins, and the second between 95 and 100 per cent pure. A third extract "3 X" contained the coloring matter which is usually estimated as tannin. The results of the experiments indicate (1) that commercial tannins are variable and probably not pure tannin, (2) that ordinary commercial tannin and pure tannin extracts are not the same, (3) that we do not know the form or quantity of tannin or tannin like substances with which the fungus comes in contact in the host plant, (4) that the food supply influences the vigor of the fungus and its power of resistance, (5) that high percentages of tannin usually cause a retardation of germination frequently followed by an abnormal growth of aerial mycelium, (6) *E. radialis mississippiensis* was most resistant, *E. parasitica* second and *E. radialis* third, (7) that the American strain of *E. parasitica* was more resistant than the Chinese strain, (8) *E. parasitica* may feed to some extent on the tannin, (9) specially prepared pure tannin extracts were less toxic than commercial tannin, (10) coloring materials which are usually estimated as tannins were toxic, (11) tannic acid is toxic to many parasitic fungi, but there are other compounds associated with it which are more toxic and which may be more important in the economy of the host plant.

A New North American Endophyllum J. C. ARTHUR and F. D. FROMME

The supposed aeciospores of *Aecidium tuberculatum* Ellis & Kellerm. were found to produce promycelia and basidiospores when germinated on the surface of water or of a non nutrient agar or gelatine. They are, therefore, to be considered teliospores of the same character as those present in the genera *Endophyllum* and *Gymnoconia*. The morphological features of this species, especially the cupulate, bullate sorus and the presence of a peridium, together with the habit of perennating in the host are characteristic of the genus *Endophyllum*.

The fungus occurs on species of *Callirhoe*, *Sidalcea* and *Aithaea* in Kansas, Nebraska, Colorado and Wyoming.

This is the first North American rust whose as-

signment to the genus *Endophyllum* has been proved by germination tests.

How to Use Aecium and Similar Terms J. C. ARTHUR.

The terms *pycnium*, *aecium*, *uredinium* and *telium* and their derivatives were introduced into the terminology of mycology by the writer in 1905. These terms were intended to meet certain definite requirements, and not as simplified forms of terms in common use. They have been accepted by many writers either wholly or in part, and have been accorded a place in recent large dictionaries. The present paper is intended to point out the application of the terms and to show wherein some extensions of the terms has developed which impairs their value and is likely to lead to confusion of ideas.

Cultures of Uredinales in 1912, 1913 and 1914 J. C. ARTHUR.

The present report continues a series extending over sixteen consecutive years on the results obtained from protected cultures of various species of rusts. Out of the very large number of trials made during the three years covered by the report, about seventy were successful in producing infection, involving about thirty species. Probably half the successful cultures do little more than confirm previous work with the same species. A large part of the remainder, however, extend our knowledge of the species considerably. Some show that what have been considered valid species, e. g., *Puccinia tosta*, *P. vulpinoides* and *P. Dulacii*, are to be reduced to synonymy. A few cultures demonstrated the full life history of species never before cultured.

The North American Species of Allodus C. R. OATON.

The genus *Allodus* of the Uredinales was founded by Arthur in 1906 and embraces those species of the genus *Puccinia* auct. which have only pycnia, aecia (aecidium type) and telia in their life cycle. The present study has been made almost entirely from the taxonomic standpoint and shows in North America about forty eight species.

Diagnostic descriptions and a key to the species are included, together with discussions and notes of interest to investigators in this class of fungi.

Foreign species have been carefully compared, but are not included in the present paper.

Correlated species of rusts in the genera *Dicocoma*, *Dasyaspora* and *Uromyces* have been enumerated so far as time has permitted, and show some interesting genetic relationships.

North American Rusts with Caecoma-like Sorus C
A LUDWIG

This paper takes up a discussion of the caecoma like stage in the life history of certain North American rusts. A caecoma is understood to be a structure in which the spores are catenulate and the sorus is not delimited by peridium, paraphyses, or similar means for preventing true coalescence of sori. The material thus included is divided into five groups represented by the genera *Coleosporium*, *Melampsora*, *Neoravenelia*, *Gymnoconia* and *Eriosporangium* (in part). An attempt is made to arrange the species of *Colcosporium* chiefly according to their morphological characters with a view to the ultimate combination of some of them, since it seems likely that there are "more species of *Colcosporium* in the books than in nature." In the *Melampsora* group one new combination is made and one new species described. In the genus *Eriosporangium* the species *E. Hyptidis* (M. A. Curt.) Arth. is shown to have a distribution limited to the United States instead of extending to the West Indies and Central America, as heretofore considered.

The Penicillium Group—Verticillatae of Wehmer
CHARLES THOM

A series of strains of *Penicillium* beginning with the asexual form of *P. luteum* and ending with *P. purpurogenum* are linked into a series by certain common characters. The conidiophore produces a single whorl of fertile branches (metulae). Wehmer uses this character to name a section, *Verticillatae*, of the genus. Each branch bears a verticil of sterigmata or conidia bearing cells, closely parallel, enlarging from the base upward 5-8 microns, then tapering to form a lanceolate point ending in a conidium producing tube, with a total length from 12 to 15 microns. The conidia in the series are elliptical, or more or less fusiform, rarely approach to globose, smooth or slightly rough, with a majority of spores in each culture, showing a size typical of the strain, while some vary widely enough to approach the range of size found in the group 2 to 3 by 2.5-4 microns. In colony character, the surface mycelium shows yellow granules which in some become reddish with age and changed reactions. The amount of yellow depends (1) upon the amount of surface growth, hence becomes abundant if the colony is floccose or is very slight in strains with short, separate conidiophores, (2) in the quantity of green conidia produced thus *P. luteum* shows only a trace of green and *P. purpurogenum* only a trace of yellow.

The species at the *P. luteum* end of the series produce orange shades in substrata containing sugars with only partial, or slow, transformation to red. *P. purpurogenum* and its close allies produce only traces of this orange color, but an abundance of a rich red coloring matter. Cultures will be shown to illustrate these points.

Spermatia of the Higher Ascomycetes B B
HIGGINS

While studying the life cycle of some fungous parasites during the last two years, spermatia have been found in some twenty species. In all cases studied they develop late in the fall simultaneous with the development of young stages of the ascocarp and, in at least eleven species, with carpogonial structures.

These twenty species are scattered through four orders of the Ascomycetes, viz., *Phacidiales*, *Perisporiales*, *Dothidiales* and *Sphaeriales*, which indicates that spermatia are of quite general occurrence and may have an important bearing on the classification and relationships of the group.

The Papulospora Question as Related to Ascobolus
B O DODGE

Species of fungi producing so called *Urocystis* like spores, papulospores, are found in several widely separated groups. Many of such forms have been connected with hypocreaceous Ascomycetes.

I have found a *Papulospora* closely associated with *Ascobolus magnificus* either as a parasite or as an asexual spore form of the *Ascobolus*. If the former is the case the mycelium of the parasite is intrahyphal, if the latter be true then the phenomenon known as "Durchwachsung" is extremely complicated in the mycelium of this *Ascobolus*.

Further recent comparisons of papulospores with those of *Urocystis* and their description as independent Hymenomycetes are quite beside the question. It is plain that they are spore bodies either of the perfect stage of the fungus with which they are associated or of a parasite upon that fungus.

The Effect of Centrifugal Force on Plants F M
ANDREWS

Climatic Distribution of the Various Types of Angiosperm Leaf Margin and Their Physiological Significance I W BAILEY AND E W SIN
NOTT

Root Habits of Desert Plants and the Reaction of Roots to Soil Temperature W A CANNON

There are three well marked types of roots of

the desert perennials. These are in brief (1) roots which never penetrate the ground deeply, whatever may be its character. Most cacti have roots of this kind, (2) roots which penetrate deeply and which have a few or no roots near the surface of the ground. A typical example is found in *Koeberlinia*, although *Prosopis*, also, usually has roots of this type. And finally, (3) many plants have roots which are intermediate between these extreme forms, and which may be said to be of a generalized character. *Covillea*, and many other species have generalized root systems.

The absorbing roots of the superficial type, type 1, lie, for the most part, from 5 to 15 cm beneath the surface, while the anchoring roots are usually not much over 30 cm deep. Since most of the roots of this type are absorbing roots it follows that most of the roots are placed close to the surface of the ground. The deeply placed roots, type 2, on the other hand, may lie from 2 m to 5 m and much deeper, and have few superficial absorbing roots. The generalized root systems may occupy any horizon between immediately beneath the surface of the ground and a depth of 2 m or over. There is apparently no differentiation into anchoring and absorbing roots in class 2 and class 3.

A study of the mean maxima soil temperatures for a depth of 15 cm and 30 cm shows that the annual swing is from 46.5° F, in January, to 94.5° F, in July, at the shallower depth, and from 39.0° F, to 87.5° F, at the greater depth. Thus there is a difference at the beginning of the most active growing season of 7° F, in soil temperatures between a depth of 15 cm and a depth of 30 cm. The temperature decreases with depth, so that as far as the records show, at depths less than 15 cm the maxima temperatures in midsummer are greatest.

From the striking difference in root habit and from the marked difference in soil temperatures which comes with variation in depth it follows that, in nature, plants having root habits of so diverse a character as has been given must needs be exposed to widely different temperature conditions of the soil.

Associated with the fact last presented is the one that perennials, with different root habits, have each their characteristic reaction to soil temperatures. For example, *Prosopis*, with a deeply penetrating root system, exhibits, so far as its roots are concerned active growth between temperatures (less than) 15° C and 42° C. While *Fouquieria*, with a root system resembling very nearly that of

the cacti, exhibits little root growth in soil temperature under 20° C, and the same is true of *Opuntia versicolor*. The rate of growth increases with temperature rise until an optimum is reached between 30° C and 35° C, although growth continues to 40° C, and above.

Thus to an extent not now known, perennials with strikingly different root types show unlike and characteristic response to soil temperatures. It is thought that the difference in temperature response, coupled with differences in soil temperature are the definite factors which bring about the characteristic distribution in the soil of the roots of the species studied. It is largely because of these conditions also that "exposures" are so important in determining the characteristic distribution of many species especially in arid or semi arid regions.

Effect of Temperature on Glomerella C. W. EDGERTON

Different species or strains of the genus *Glomerella* respond differently to different temperatures. One form, the one found on bean, *Colletotrichum lindemuthianum*, is very susceptible to high temperatures, growth ceasing at about a temperature of 31° C, thus explaining why this form is not prevalent during the hot part of the summer or in warm climates. The different *Glomerella* strains fall into several classes in regard to the temperature factor. These classes are represented by such forms as *Colletotrichum lindemuthianum*, *Colletotrichum lagenarium*, a slow growing form from apple, a fast growing form from apple, and *Gloeosporium musarum*. Nearly fifty different cultures have been grown at temperatures ranging from 14° C. to 37.5° C.

The Nature of Antagonism W. J. V. OSTERHOUT

As the result of his studies on permeability the writer finds it possible to predict what substances will antagonize each other in their action on living tissues. This opens the way to a general theory of antagonism.

The Chemical Dynamics of Living Protoplasm

W. J. V. OSTERHOUT

By means of electrical measurements it is possible to follow reactions in living protoplasm without interference with the progress of the reaction or injury to the protoplasm. It is thus possible to determine the order of the reaction and to ascertain whether the reaction is reversible. It appears in many cases that the reaction is reversible up to a certain point, beyond this it is irreversible. The reasons for this are discussed.

The Nature of Mechanical Stimulation W J V
OSTERHOUT

The chief difficulty which a theory of mechanical stimulation must meet is the production of chemical reactions by a mechanical disturbance. This difficulty is met by supposing that the mechanical disturbance breaks down semipermeable surfaces, thus allowing substances to react which were previously kept apart. Experimental evidence is brought forward in support of this view *Studies in Plant Oxidases* G B REED

1 *Evidence for the General Distribution of the Oxidases*—Some algae which have been reported to be without oxidases were found to contain a ferment capable of activating the oxidation of a specific group of compounds.

2 *The Formation of Indophenol Granules*—Indophenol granules were found to form in cells which had been killed by agents which do not affect oxidases, but did not form in cells killed by agents known to destroy oxidases.

3 *On the Separation of Oxidase Reactions from the Catalase Reaction*—By subjecting colloidal platinum to active oxygen at an anode its oxidase activity towards gum guaiacum and potassium iodide was increased, while its catalase activity was decreased, and by treating with active hydrogen at a cathode the opposite effects were produced. Bright platinum after anodic oxidation has a definite oxidase action, but no catalase action. Some plant extracts were found which contained oxidases, but no catalase.

4 *An Acid stable Oxidase*—While the oxidases are ordinarily inhibited by a slight degree of acidity, an oxidase was obtained from pineapples and some other fruits capable of withstanding 0.1 M HCl.

Enzymes of the Marine Algae A R DAVIS

Continuing the work begun with *Fucus*, isolation and identification of enzymes occurring in representative marine forms of the greens, browns and reds has been carried on. The results obtained show certain differences for the different groups of algae: carbohydrases attacking the various polysaccharides are generally distributed in the greens and reds, when present in the browns they are much less active, and in a few genera have not yet been detected with the methods used. Compared with potato leaf tissue prepared in the same way, the carbohydrase activity of *Ulva lactuca*, the most active form studied, was about half.

Proteinases acting upon albumin, legumin and

peptone in neutral and alkaline solution were isolated from the majority of the forms worked with and, as was true for the carbohydrases, were most active in certain of the greens and reds. No amylase action was observable.

With the exception of a few forms lipase was found to be very generally present, being especially active in *Chondrus* and *Desmarestia*, on the other hand, fatty esters were not acted upon.

Oxidases and peroxidases were found in but one form—*Agardhiella*. In this both were quite active, comparing favorably with potato tuber tissue. Catalases were present in all forms.

The total number of enzymes isolated was small when compared with the tissues of the higher plants and their action decidedly slower. In general this action was greater in the greens and the reds than in the browns.

Concerning the Measurement of Diastase Activity in Plant Extracts CHAS O APPLEMAN

Several methods have been proposed for the measurement of the velocity of diastase activity in plant extracts. The procedure adopted by several investigators is based upon the determination of the amount of reducing sugar, usually calculated as maltose, produced by the action of a definite amount of extract upon an excess of soluble starch for a definite length of time at constant temperature. The Kjeldahl "law of proportionality" is sometimes observed and sometimes ignored. The general inapplicability of this method for plant extracts is very strikingly shown in the following table which refers to the diastase activity in glycerine extracts from cold storage potatoes.

TABLE I
Increase in Milligrams of Sugar at 40° C Per
Hour Per 100 Grams of Potato Pulp

Date of Analysis	Total Reducing Sugar Calculated as Maltose	Total Sugar
November 28	17.0	8.6
December 20	24.6	3.7
January 13	81.9	3.7

Calculated on the basis of increase in total reducing sugars or maltose in the extract after incubation with soluble starch, the tubers would show a very marked increase in diastase with storage, but when calculated on basis of increase in total sugar, the diastase activity remains practically constant. The amount of sucrose in the tubers increases with cold storage. It is extracted with the diastase and is inverted at the incubation temperature, according to the law of the mass action.

Since non reducing, hydrolyzable sugars are present in many plant tissues and are subject to wide variation in the same tissue, the above described method in unmodified form is not reliable

Electrolytic Determination of Exosmosis from the Roots of Anesthetized Plants M C MERRILL

Subjecting growing plants of *Pisum sativum* to the influence of illuminating gas and ether vapor causes a marked exosmosis from the roots. The plants were grown for several days in full nutrient solution and, after thorough rinsing of the roots, were placed in redistilled water whose specific conductivity was approximately 000002. Immediately afterward the plants were subjected for varying periods to the gas or vapor, and the effect determined by frequent measurements of the conductivity of the water as contrasted with that in which control plants were placed and also by subsequently growing fresh seedlings in the water.

The exposures were made in all cases under bell jars. Where the roots were exposed directly to the anesthetics the resulting exosmosis was more rapid than where the roots were kept in the water during the exposure. In the former case the root turgor decreased greatly, while in the latter case the tops were affected, but the roots remained normal in appearance even though the exosmosis was abundant, thus indicating a disappearance of mineral nutrients from the tops. With older plants the increased conductivity was less than with younger plants thereby indicating greater resistance to the anesthetics.

Some Relations of Plants to Distilled Water and Certain Dilute Toxic Solutions M C MERRILL

A careful determination was made of the interval during which *Pisum sativum* seedlings could grow in redistilled water and in certain toxic solutions, and then recover when later placed in full nutrient solution. The benefits to be derived from renewing the distilled water every four days, as contrasted with the condition where it was not renewed, were evidenced in most cases by better growth in the distilled water or greater recovery in the full nutrient solution. Horse beans (*Vicia faba*) were more marked than *Pisum sativum* in their behavior toward the renewal of the distilled water, those in which the distilled water was renewed showing more than double the growth. Bacterial and fungous action is undoubtedly an important factor, as demonstrated by the effect of boiling the water. The evidence indicates that there are several factors entering into the so called harmful action of distilled water. Striking

changes in the conductivity of the distilled water were found when plants were placed in it during various stages and conditions of growth.

Vegetation of Abandoned Roadways in Eastern Colorado H L SHANTZ

A roadway consisted of a trail formed by driving repeatedly over the short grass sod. After a few years a new road was formed at the side of the old trail. In this way many roads were formed and successively abandoned. The plant succession on these abandoned roadways consists of an early and late ruderal association followed by either the *Artemisia Gutierrezii* association or the wire grass association. The final stage or Grama Buffalo grass association becomes established in from twenty to thirty years.

Is the Flora of the Prairie and Steppe of Arctic Origin? B SHIMEK

The conclusion of the paper is opposed to the widely prevalent conception that the flora of the steppes (and incidentally of the prairies) is of Arctic origin, and that the "steppe" condition is an evidence of a colder climate. The fact that certain plants (and even more conspicuously, certain animals), more particularly in Europe, are now found only in the far north, but formerly extended much farther south, is not regarded as evidence of a much colder earlier climate in these more southerly regions, for we probably have to deal here with remnants of a formerly widespread flora and fauna now largely restricted through man's influence.

Comparisons are made of plant lists showing distribution in both Europe and North America, and on this basis, and on the basis of structural adaptation to habitat, and habit, the conclusion is drawn that the plants of these treeless areas reached their present state under the influence of dry conditions, and that their present distribution was accomplished by advance from regions south of the glacial limit.

Growth forms of the Flora of New York and Vicinity NORMAN TAYLOR

The study of climate, through the study of the vegetative response to it, involved the dividing of all vegetation into 10 or 12 different categories. Raunkiaer has called these "growth forms," which are based on the amount and kind of protection exhibited by the growing or perennating shoots during the winter or critical season. The usefulness of the method lies in its value as a basis of comparison between different floras, different elements of the same flora, and even smaller cate-

gories of vegetation. By calculating the percentages of the growth forms in the flora of different regions, we get the record of the vegetative response to climate, with all its infinite variation. Applying the method for the flora of the vicinity of New York, where, excluding weeds, ferns and parasites there are 1907 wild species the percentages of growth forms are as follows:

Megaphanerophytes	52 per cent
Mesaphanerophytes	4.03 per cent
Microphanerophytes	7.18 per cent
Nanophanerophytes	3.51 per cent
Chamaephytes	5.29 per cent
Hemicryptophytes	33.29 per cent
Geophytes	20.23 per cent
Helophytes and Hydrophytes	11.74 per cent
Therophytes	13 per cent

The percentage of geophytes is larger than that for any region yet studied leading to the conclusion that the climate near New York is of such a nature that the development of geophytes is especially favored. Studies were also made on the northern and southern elements of the flora of New York, and on the high mountain species of the region the percentage of growth forms being given for each of these groups and for different regions of the earth's surface to compare with the local flora near New York.

The Effect of Breeding and Selection upon the Percentage of Total Alkaloids in some Species and Hybrids of the Genus Datura FRED A. MILLER AND J. W. MEADER

Through selection and hybridization an attempt has been made to develop a strain of stramonium which would show an increased percentage of alkaloids over that of the commercial stramonium leaf used for medicinal purposes. All selected plants have been carefully inbred. The alkaloidal assays have been made upon samples of air-dried leaves from individual plants. The species so far used are *Datura stramonium* L., *D. tatula* L. and *D. ferox* L.

On the Nature of Mutations R. RUGGLES GATES
Hybrids of Enothera biennis Linnaeus and O. franciscana Bartlett in the First and Second Generations BRADLEY MOORE DAVIS

Among the contrasting characters of the parent species is one especially well adapted to a genetic study. In *Enothera biennis* the papillae at the base of long hairs follow the color of the green stems, in *O. franciscana* the papillae are bright red. Hybrids of reciprocal crosses all

have red papillae, the color thus appearing as a simple dominant. Cultures of the hybrids in the second generation totaled 1806 plants from sowings of 3554 seed-like structures, 1679 rosettes sent up shoots during the season, and on every one of these plants the papillae were bright red. There was thus a failure of the color character to segregate in the F₂ in cultures containing 1,679 plants and its behavior was not what might have been expected from Mendelian experience. However it should be noted that of the 3554 seed-like structures sown 1748 failed to germinate, although seed pans were kept for 8-10 weeks. Also that 127 plants either died during the season or else, remaining as rosettes failed to send up shoots upon which observations could be made. It is thus possible that the absence of a class of green stemmed recessives may be associated with this high degree of seed sterility, the cause of which is as yet not known, or with the failure of some plants to mature.

In previous papers mention has been made of the fact that the F₁ hybrids of the cross *franciscana* × *biennis* in many characters were similar to *Enothera lamarckiana*, differing from this plant only in relatively small plus or minus expressions of these characters. The second generation of this cross, as was to have been expected, presented a wide range of forms and among these were a number of plants with combinations of characters that appear to have fulfilled in essentials the requirements of a synthetic *Lamarckiana*-like hybrid. Further generations from these selected plants will be grown to test their further range of variation.

A detailed account of the above considered cultures will later be published.

Inheritance of Certain Seed Characters in Corn R. A. HARPER

The various pigmentations of the integument, aleurone layer and endosperm are mendelical characters in Dettos sense, that is, the same in the cells as they are in the tissues or the kernel, as a whole. The pattern in the case of streaked or mottled grains is a character of the tissue, as a whole. The form of the dent kernels is a character of the kernel, as a whole, due to the nature and distribution of the starch and other elements in the tissues. The wrinkled form of the kernels of sweet corn is more nearly identical with the shrinkage of the individual cells of the endosperm. By crossing, intermediates may be obtained between any two such contrasting charac-

ters, and selection tends to develop fixity of type, though the range of variation may at first be even higher than that of the parent types

Inheritable Variations in the Yellow Daisy (Eudbeckia hirta) ALBERT F. BLAKESLEE

Variations in the following characters have been found in the wild yellow daisy: absence of rays and their presence in rather definite numbers from 8 to 30 and to perfectly double forms, width of rays, diameter of head from 1 to 5½ inches, color of rays from pale straw color to deep orange, relative intensity of color in inner half of ray forming a lighter or darker ring, different intensities of mahogany color at base of ray on upper side, mahogany on under side of ray, constriction of ray at tip at middle, or at base—those constricted at tip either rolled in or rolled out to give the "cactus" type seen in *Dahlias*—those constricted at base without change in color or characterized by lighter color or by presence of black pigment on constricted areas, transformation of rays into tubes giving "quilled" type, the position of rays, bending upward, horizontal, reflexed, straight or variously twisted, the shape and size of disk, the color of disk from yellowish green through several grades of purple to almost black, vegetative characters such as height, branching, size and shape of leaf, fasciations, etc.

Evidence from the distribution of the variants in nature and from their reappearance in sowings from open pollinated heads shows that most, if not all, these variations are inherited. The basal splash of mahogany on the ray seems to be inherited as a simple Mendelian dominant. Other characters are being investigated.

Bud Variations in Coleus A. B. STOUT

The phenomena of bud variation in *Coleus* and the behavior of pedigreed plants of vegetative propagation illustrate, in the case of red pigmentation, most clearly the behavior of a metidentical character and show equally well that the distribution of colors in patterns is epigenetic in nature, and is, without doubt, due to physical and chemical processes quite analogous to the Liesegang precipitation phenomena by which Gebhardt reproduced in a most striking manner certain markings that occur in the wings of butterflies.

Plants propagated vegetatively through six generations developed two types of changes: (1) fluctuations and (2) mutations. Although the different patterns which arose were remarkably constant in vegetative propagation, each exhibited further changes in the epigenetic development and

distribution of the red pigmentation. The phenomena associated with the appearance and subsequent behavior of the different bud variations are quite similar to the phenomena of variation, mutation and alternative inheritance in a seed progeny of hybrid origin.

The Morphology of the Enothera Flower GEORGE HARRISON SHULL

The hypanthium of *Enothera* and other Onagraceae genera is usually described in taxonomic works as a "calyx tube." In one of my hybrid *Enotheras* a complete series of transitional stages was presented connecting the normal type of flower, sessile with a long hypanthium, with pedicellate flowers wholly lacking a hypanthium. This indicates that the hypanthium is of cauline nature.

The Morphology and Systematic Position of Podomitrion D. H. CAMPBELL

The genus *Podomitrion* comprises two species, *P. phyllanthus* from the Australasian region, and *P. Malaccense*, which has hitherto been reported only from Singapore and New Caledonia. The writer collected the latter species in Borneo and the Philippines.

Podomitrion malaccense closely resembles in appearance a *Blythia*, and sterile plants are indistinguishable. The position of the reproductive organs of the former, in special ventral branches, at once distinguishes it from *Blythia*.

The anatomy of the thallus, as well as the form of the apical cell is practically identical in *Podomitrion* and *Blythia*.

The antheridia in *Podomitrion* are borne on special ventral shoots. In structure, and in the scales covering them, they most nearly resemble *Morkia* or *Calycularia*.

The archegonia are also borne in special shoots. The archegonial receptacle is very much like that of *Blythia*. The embryo is much like that of *Blythia* or *Symphyogyna*, but the basal appendage (haustorium) is somewhat less developed.

The fully developed sporophylls closely resemble that of *Blythia*, from which it differs in the more clearly marked foot, and in the presence of a over well developed apical elaterophore. The spores, in size and surface sculpturing, are hardly distinguishable from *Blythia radiculosa*.

On the whole, *Podomitrion* seems to be more nearly related to *Blythia* than to *Melagieria*, with which it is usually associated. This study of *Podomitrion* confirms the view that there is no certain distinction to be drawn between the families Anacardiaceae and Blythiaceae.

Fiber Measurement Studies, Length Variations Where They Occur and Their Relation to the Strength and Uses of Wood ELOISE GERRY

I The results of the study of one white pine tree indicate (These are based on the measurements made on 6,600 fibers from 66 specimens)

1 The length of fibers varies with their position in the tree

A In (1) a disk from the butt (age 250 years, distance above the ground approximately two feet) and in (2) a disk near the top (about 82 feet above the ground) the shortest fibers were found near the pith. An increase in length was apparent from the center outward. This was somewhat irregular (slides). No constant fiber length was attained.

B In 26 bolts, taken at about 2½ to 3 inches from the pith, at 4 foot intervals between the butt and the top of the tree, a tendency toward an increase in average fiber length was apparent for about two thirds of the height of the tree.

2 The relation between the fiber length and the strength values of the wood was indeterminate. No direct effect dependent on length alone could be found. The following indications were obtained however:

A From butt to top the S G and strength decreased but the average fiber length increased.

B In some loblobly pine the late wood was about twice as strong as the early wood. The relative fiber length was as 2.69 is to 9.03 mm.

C In Rotholz the fibers are also stronger (in compression) and shorter than those in normal wood.

That is, the shortest but at the same time the thickest walled fibers were present in the strongest specimens.

II The general range of variation in fiber length was not found to be greater within the species than in the individual tree.

1 Longleaf pine (*Pinus palustris*) (1,700 measurements of 15 specimens)

2 Douglas fir (*Pseudotsuga taxifolia*) (900 measurements of 5 specimens)

The longest fibers were found in the earliest springwood, the length then decreased gradually and the shortest fibers were present in the last formed layers of the ring.

III Certain general relationships also noted

1 The root fibers of longleaf pine and white pine were found to have a fiber length as long as or even longer than that of the trunk fibers. This may enable the pulp mill to utilize stumps ob-

tained where land is being cleared or the chips from which resin has been extracted for a strong craft pulp.

2 In general the hardwoods or angiosperms have a shorter fiber than the softwoods or gymnosperms. All other things being equal the strength of a pulp varies with the length of the fibers composing it.

3 The early or springwood fibers are always longer than the late or summerwood fibers. The data obtained from about 80 specimens indicated that less than one fourth of the fibers found in every hundred macerated fibers were summerwood. In two cases the summerwood fibers made up about one third of this amount. In both cases this large number of fibers was found in wood from very low down in the tree. The per cent and character of the summerwood fibers are significant factors in determining the character of a wood to be used for pulp.

Changes in the Fruit Type of Angiosperms Coincident with the Development of the Herbaceous Habit F. W. SINNOTT AND I. W. BAILEY

Angiosperms with fleshy fruits are almost invariably trees, shrubs or climbing herbs. Terrestrial herbs practically always have dry fruits. Herbs seem to have been developed from woody plants in relatively recent times. It is therefore evident that with this change in habit there must have been changes in many families from a fleshy type of fruit to a dry one. This is apparently due to the fact that most frugivorous birds are reluctant to feed on the ground and that herbs have consequently been obliged to develop new methods for seed dispersal.

Some Effects of the Brown-rot Fungus upon the Composition of the Peach LON A. HAWKINS

This paper describes the results of several series of experiments on the effect of the brown rot fungus upon certain carbon compounds in the peach fruit. In the experiments one half of the peach was inoculated with the fungus while the other was retained sterile under the same moisture and temperature conditions as a control. At the end of two or three weeks the two portions were analyzed. It was found that in the rotted portion the pentosan content was practically the same as in the sound half, the acid content was increased, the amount of alcohol insoluble substance which reduces Fehling's solution when hydrolyzed with dilute HCl was decreased, the total sugar content was decreased, while the cane sugar practically disappeared.

Senile Changes in the Leaves of Vitis vulpina and Certain other Perennial Plants H. M. BENE DICT

It has been found by an investigation extending through a period of seven years that in the leaves of *V. vulpina* and other plants there occurs evidence of senility. Similarly aged leaves of differently aged plants (age being reckoned from date of last reproduction from seed) show marked differences in the extent of veinage. The aggregates of mesophyll cells enclosed within the smallest veinlets, which may be termed vein islets, are uniformly smaller in leaves of old plants than in leaves of young plants. In other words, leaves of old plants have a higher percentage of vascular tissue than leaves of young plants, consequently they are less efficient photosynthesizing organs, and this has been proved by experiment. A formula is presented showing the method for determining age of *Vitis vulpina* from the character of its veinage. The juvenile veinage is restored only after sexual reproduction. Finally, a theory of senility is proposed, based upon loss in permeability.

Influence of Certain Salts on Nodule Production in Vetch MA. KNO

Calcium salts are essential for nodule production in vetch. The substitution of borium or strontium to a limited degree permits also of nodule development. The relation of balanced solution to nodule production has also been investigated.

Physiological Studies of Bacillus Radiocola of Soy Bean J. K. WILSON

This investigation confirms earlier work as regards the influence of nitrates on nodule production, and indicates in addition that sulfates in relatively weak concentration inhibit the process. Chlorides and phosphates stimulate nodule production, while ammonium salts are inhibitory. The significant fact was developed that while nodule development was prevented by the presence of nitrates, phosphates and ammonium salts, yet the organism retained its vitality in the presence of these salts. Whether the effect of the salt is upon the root, such as to make it resistant, or upon the organism can not yet be stated.

Direct Absorption and Assimilation of Carbohydrates by Green Plants LEWIS KNUDSON

Confirming and extending the work of Laurent, Molliard and others, it has been found that a variety of plants are able to absorb and assimilate

various sugars, including lactose. Plants employed are timothy, vetch, onion, radish, pea, cabbage, clover, flax and corn. Lactose has been found to be utilized by vetch, radish and onion but not by timothy. For corn the sugars in order of "preference" by the plant are glucose, levulose, cane sugar and maltose, for vetch, cane sugar, glucose, maltose and lactose. Experiments on the influence of concentration of the sugar on growth, influence of sugars in respiration and color production have also been made. A study of the influence of sugars in enzyme production is now progressing.

A Preliminary Study of the Chlorophyll Compounds of the Peach Leaf HOWARD S. REED AND H. S. STAHL

The investigations were undertaken with especial reference to the foliage of peach trees having "yellows." The chlorophyll compounds were extracted and separated by the use of inactive solvents. The diseased leaves differ from the healthy in both the quality and quantity of chlorophyll derivatives extracted. The derivatives have been identified by their color, solubility, spectra and other properties.

Among others the following derivatives have been found in healthy peach leaves: chlorophyll *a*, chlorophyll *b*, phytylorodin, chlorophyllin, pheophytin, pheophorbide, methyl pheophorbide, methyl chlorophyllid, phytychlorin, carotin and xanthophyll.

As the disease advances there is a decrease in the quantity of both chlorophyll and chlorophyll derivatives. The diminution of the green series is greater than that of the yellow brown series.

Respiration in Apple Leaves Infected with Gymnosporangium HOWARD S. REED AND C. H. CRAIGILL

The respiration of apple leaves has been studied with reference to the pathological effects of infection. Foliage was studied at various stages in the development of the disease, using both Ganong's respirometer and Sachs's baryta methods. The diseased leaves uniformly produce more carbon dioxide than healthy leaves in the same intervals. Various factors influence the process.

The Absorption and Excretion of Electrolytes by Lupinus albus in Dilute Simple Solutions of Nutrient Salts R. H. TRUE AND H. H. BARTLETT¹

¹ Office of Plant Physiological and Fermentation Investigations, Bureau of Plant Industry, U. S. Department of Agriculture.

The behavior of seedlings of *Lupinus albus* toward distilled water and toward simple solutions of salts containing ions regarded as essential to the normal nutrition of higher green plants was studied by the water culture method, the plants being kept in darkness. The stronger concentrations employed were comparable with the soil solution under conditions found in the vicinity of Washington, D. C. The absorption of ions from the solutions and the loss of ions to the solution were measured by the Wheatstone bridge in terms of change of electrical conductivity.

The plants give up their salts to distilled water at a variable rate until death ensues from exhaustion. Solutions of KH_2PO_4 and KCl act essentially like distilled water.

In K_2SO_4 and KNO_3 a slight absorption phase is seen in the most favorable concentrations resulting in a minimal net gain in electrolytes to the plant. Otherwise the results differ little from those seen in the phosphate and chlorid solutions. Sodium chloride affects permeability and growth essentially like KNO_3 and K_2SO_4 .

In the most favorable concentrations of $\text{Mg}(\text{NO}_3)_2$ and MgSO_4 , there is a slight but clearly developed absorption phase resulting in a net gain of electrolytes to the plant. A net loss takes place in the more dilute solutions and in the greater concentrations toxic action develops.

In $\text{Ca}(\text{NO}_3)_2$ and CaSO_4 solutions all concentrations studied support an active absorption of electrolytes and apparently enable the plants not only to retain the salts already present, but also to make net gains from the solutions.

The Absorption and Excretion of Electrolytes by Lupinus albus in Dilute Solutions Containing Mixtures of Nutrient Salts. B. H. TRUE AND HARLEY HARRIS BARTLETT.

Seedlings of *Lupinus albus* were grown in darkness in graded solutions of pairs of nutrient salts, the higher concentrations being comparable with the soil solution. Absorption or excretion of electrolytes by the roots was measured as changes of electrical conductivity.

The results obtained show that the gain or loss of electrolytes by the plants is in cases influenced by the antagonistic action of ions.

The Transpiration Rate on Clear Days as Modified by the Daily Change in Environmental Factors. LYMAN J. BRIGGS AND H. L. SHANTZ.

The transpiration of a number of crop plants has been measured by means of automatic balances at Akron, Colorado, during the past three

years. Automatic records have also been secured of the evaporation from a freely exposed water surface, the depression of the wet bulb, the intensity of the solar radiation, the air temperature and the wind velocity. The present paper compares the results of such measurements for clear days. The transpiration curves are based on a large number of measurements, and expose the normal behavior of these plants on clear days.

Relation of Transpiration to the Composition of White Pine Seedlings. GEORGE P. BURNS.

The experiments reported at the Atlanta meeting were repeated during the summer of 1914, with the addition of two beds in which the physical conditions were changed by means of one and two covers of cheesecloth. The seedlings were grown in five beds each with a different rate of transpiration.

Seeds were sown in May and the first analysis was made of seedlings gathered August 11. This analysis showed the following amounts of protein and soluble ash:

Seedlings	Protein Per Cent	Soluble Ash Per Cent
No shade	13.88	4.13
Half shade	16.44	4.41
Full shade	36.82	6.46
One cheesecloth	11.56	4.14
Two cheesecloth	12.31	4.15

This table again shows the high percentage of ash in the full shade bed where the rate of transpiration was very low.

A New Method in Lichen Taxonomy. BRUCE FINK.

The results of investigation of the Collemales will be presented. The plants will be treated as fungi and a new type of lichen diagnosis will be presented. This will treat the anatomical characters of the lichen to the exclusion of those features of the algal host which have heretofore been included in the descriptions of these lichens. The characters of the cortices and medulla have been carefully investigated, and several features will be presented which are new to lichen taxonomy. The sex organs have for the first time been studied with a view to ascertaining their value as diagnostic characters. Camera lucida drawings of cortices, medulla, apothecia, procaryps and spermatogonia will be shown, and their taxonomic value will be discussed.

The Mechanism for Discharging the Eggs of Dictyota dichotoma. W. D. HOYT.

The young eggs of *Dictyota dichotoma* are enclosed by thin walls showing no differentiation,

but as they mature their walls thicken and become differentiated into a thick inner and a thin outer layer. At the instant of discharge the inner layer swells and becomes gelatinous, the outer layer is irregularly ruptured, and the egg is forced through the opening, thus formed, sometimes to a distance of 0.24 mm. In escaping the egg is still enclosed by the gelatinous inner layer, but is soon set free by the solution of this layer.

The observed facts indicate that the force utilized in discharging the eggs is obtained solely by the swelling of the inner layer with the contraction of the stretched outer layer of the oogonium wall.

Both at Beaufort, N C, and at Naples, about 65-75 per cent of all the eggs of each crop were discharged within a single hour of a single day, beginning at about the time of the first observable traces of dawn.

The swelling of the inner layer of the oogonial wall with the resultant discharge, did not occur in eggs that were killed by heat, cold or chemicals and was practically or entirely prevented by anything that interfered with the life conditions. It could not be initiated by any means before the usual time for discharge, but, as the usual time approached, seemed slightly accelerated by transfer from a moist dish to sea water.

The above facts seem to indicate that the swelling of the inner layer of the oogonial wall is under the direct control of the protoplasm, or that it is accomplished by means of enzymes formed by the protoplasm and affected by the same conditions that affect the living substance. Of these two possibilities, the latter seems more probable.

Cell Division and the Formation of Colonies of Volvox R. A. HARPER.

The planes of the first two divisions of the mother cell of the young colony intersect at right angles. The plane of the third division lies so as to form the well known cross figure. The factors determining this deviation from Sach's principle of rectangular intersection are associated with the surface tension developed in a plate made by successive bipartition of cells, and lead to the further incurving of the plate and formation of the globular colony.

Prochromosomes in Synapsis C. A. DARLING.

The work on prochromosomes by Rosenberg, Overton and others has suggested the possibility that some cells might be found the study of which would considerably increase our knowledge concerning the behavior of the chromosomes in synap-

sis and reduction. Such cells have been found in the Norway Maple *Acer platanoides*.

In the so called resting stage of the nucleus of the pollen mother cell in this species are 26 definite bodies corresponding in number to the 26 chromosomes found in the vegetative cells at the time of division, most of these bodies, or prochromosomes, are distributed about the periphery of the nucleus but a few are to be found lying close to or against the nucleus. Upon staining with safranin, gentian violet and Orange G, these 26 prochromosomes are stained blue and the nucleolus red so that the two are readily distinguished. At this stage the linear threads take the stain only sparingly. At least some of these threads appear to be attached to the prochromosomes, in some cases the threads are connected, forming a sort of net with nodes or thickenings, these nodes do not take the gentian violet stain and are not definite bodies like the prochromosomes.

The prochromosomes are noticeably arranged in pairs, in some cases the two are separated by at least twice their own width while in other pairs they almost touch each other, in no case do they appear to be connected. The prochromosomes vary somewhat in size, but so far as observations go the individuals of a pair appear to be equal.

As the period of synapsis approaches, the threads become more conspicuous and take the gentian violet stain more readily, the prochromosomes still retaining their definite individuality appear to come closer together. The beginning of synapsis is indicated by the contents of the nucleus being drawn toward the nucleolus and collecting at one side of the nuclear cavity. The whole network of threads and prochromosomes becomes more or less massed, only in rare cases do any of the threads appear to lie parallel.

In complete synapsis only a few threads are distinguishable, especially those extending out from the synaptic knot. The prochromosomes, however, are still very apparent, in most pairs the members appear to be in contact with each other although some are still separated. As growth proceeds the threads which extend outside of the knot become thicker and contain more chromatin, as shown by their staining reaction. These threads soon become double, the evidence indicating that this is due to a longitudinal splitting of a single thread rather than to the parallel arrangement of two separate threads. Apparently each of these thick threads is formed by the gradual flowing out of the contents of the prochromosome.

comes on the thin threads to which they were attached before synapsis began, the contents of the two individuals of a pair flowing in opposite directions.

As the growth period advances these threads enlarge, become less entangled, and the splitting becomes more apparent. At this stage deeper staining bodies of different sizes are found distributed on the threads, these bodies possibly chromomeres, are always found in pairs, one on each of the two parts of the double thread. There are usually 3 or 4 pairs of these chromomeres on each of the bivalent threads, the individuals of each pair being opposite each other and equal in size. As these bivalent threads become less entangled the number of the threads is found to be 13, one half the number of prochromosomes observed before synapsis. The details from this stage on have not as yet been worked out but observations indicate that each of these 13 threads becomes shorter and finally forms a bivalent chromosome.

In the first division of the nucleus 13 chromosomes pass to each pole, in the reconstructed daughter nucleus 13 prochromosomes appear but these are not arranged in pairs. In the resting nuclei of the somatic tissue the prochromosomes are present and appear to be more or less in pairs.

These observations seem to show that in *Acer platanoides* prochromosomes exist in the nucleus that they are arranged more or less in pairs in both somatic and mother cells, that in synapsis the members of each pair unite and form a thick thread on the single thread which preceded synapsis, that this single thick thread becomes split longitudinally, that upon this bivalent thread occur paired chromomeres, and finally that each bivalent thread becomes a bivalent chromosome which divides into univalent chromosomes in the first division of the pollen mother cell.

Cytology of *Spheroplia* E. M. GILBERT

Cleavage begins with constrictions from the plasma membrane, and the cell contents are cut into masses of varying sizes. A single row of large cells or a double row of smaller cells may be found in a single filament.

All eggs at first contain more than a single nucleus, and all but one of these disappears before the egg is fully mature.

Nuclear divisions as far as observed are mitotic and no indications of amitotic divisions, described by earlier investigators, have been found. There is no fragmentation of the nucleole to form the chromosomes.

The number of pyrenoids found in eggs varies from two to seven.

The pyrenoids vary greatly in size and each is made up of a varying number of segments. The starch is usually laid down around the pyrenoid in definite layers but at times the arrangement is very irregular. Stromatic starch is very abundant in some mature eggs.

The pyrenoids disappear from portions of filament which are active in the formation of sperms.

Fertilization does not take place until the egg is fully formed and rounded at this time the egg nucleus lies in the center of the egg.

In Anatomical Study of the Root of *Ipomoea batatas* FLORENCE A. MCCORMICK

A preliminary paper on the anatomy of *Ipomoea batatas*. During the investigation, a fungus, similar to the one found in *Solanum tuberosum* has been found in the endodermis of the root, but so far the fungus has not been seen in the stem.

The Anatomy of a *Protomyces* Gall ALBAN STEWART

The lower parts of the stems of *Ambrosia trifida* L. are often attacked by *Protomyces andrusi* Lagh. causing considerable disturbance in the tissues of the host. Large swellings are caused by this parasite one or more of which may appear on the same plant.

Sections of these galls show, among other things, an increase in the tissues of the bark, an abnormal growth of the fibrovascular bundles as compared with non infected parts, close by, a broadening of the rays and the formation of other parenchyma elements in the bundles, areas of cambiform cells in the pith.

A gall caused by an unknown insect, probably of the order Lepidoptera, also occurs on the stems of this species of *Ambrosia*. The changes induced by this insect in the tissues of the host are similar in certain respects to those caused by *Protomyces*.

The Anatomy of the *Punctatus* Gall ALBAN STEWART

Andricus punctatus Bask., a hymenopterous insect of the family Cynipidae, causes large woody galls on the stems and branches of *Quercus velutina* Lam. and other closely related species of oak. This gall possesses, among others, the following anatomical characters which are of especial interest.

A recapitulation of a similar condition of ray structure to that which occurs in traumatic wood

of related species of oak. Other characters which agree closely with general conditions in traumatic tissue are as follows: A vertical shortening of the broad rays. The presence of knarls which appear only in tangential sections of the gall. A parting of the fibers to right and left in the vicinity of the larval chambers. Areas of isodiametric parenchyma cells with lignified walls, and a shortening of many of the other cells of the wood. A reduction in the number or an entire lack of vessels. Absence of distinct annual rings of growth. A suggestion of a return of the cambium to its normal activities in the outermost layers of wood. Woody inclusions in the bark.

The Anatomy of a Peridermium Gall ALBAN STEWART

Large woody galls occur on the branches of the jack pine *Pinus Banksiana* Lamb, which are caused by an infection of *Peridermium* (*Aecidium*) *cerebrum* Pk. The following anatomical differences occur in the woody portions of these galls as compared with the normal wood of this species of pine. A greatly increased production of woody tissue. An increase in the number, and a broadening of the rays both vertically and tangentially characters which also appear in traumatic wood of this species. The presence of knarls in tangential sections. A greatly increased production of resin canals in the gall but no such increase in the normal wood close by. A shortening of many of the tracheids as well as blunt end walls and wavy side walls of the same. Cells which partake of the character of both tracheids and parenchyma cells in their pitting. Alternate as well as opposite arrangement of pits in the walls of the tracheids. Apparently an absence of bars of *Sano* from the walls of the tracheids in many instances.

A Note on the Leaf Anatomy of Avicennia ALBAN STEWART

On the Forms of Castela galapagensis Hook. f. ALBAN STEWART

Photographing Mosses A. J. GROUT

When beginning the study of mosses I found identifications very difficult because of the lack of suitable and adequate literature and illustrations. I did not have access to Sullivan's "Icones" or the "Bryologia Europaea."

When as an advanced student I had access to these works I formed the ambition to put similar but cheap and simplified books within the reach of any enterprising student. My desire was to make new moss students instead of new moss

species, because what we need to advance bryology in America is, first of all, more observers and collectors.

The two books I have published were illustrated by drawings, many of which were taken from the standard works mentioned above. But I saw how valuable photographs were in the study of flowers, ferns, etc., and I became ambitious to equal this work in the mosses and hepatics. To this end I have devoted my spare time for the past year or two, and I have succeeded in enlisting others. Professor Holzinger has done some excellent work.

My outfit is a Bausch and Lomb camera for microphotography with a heavy iron base and long bellows. Instead of the cap to fit over the eye piece of the compound microscope I put in a lens board or boards. I have a battery of three lenses, a Wollensack Anastigmatic F 68 for a 4 by 5 camera and a supplementary lens to shorten the focus. A Beck Neostigmat 3 in focus, f 35 wide angle from a motion picture camera and a Bausch and Lomb wide angle Zeiss protar, focal length 2 1/2 inches.

The Wollensack and supplement give magnifications up to 5 diameters and the automatic shutter makes it more convenient than the others, which have to be uncapped. Also it gives plenty of illumination for focusing. The Beck gives magnifications up to 7 diameters and also admits plenty of light for focusing. The Zeiss protar is so small that focusing is difficult unless bright sunlight shines on the object but I can get 9 diameters. To get depth the lenses were stopped down to 32 64 or even to 128 U S and in strong light were given from 3 min. at 32 U S to 6-8 min. at U S 64 when cloudy bright and indoors.

If the mosses were not dry the setae would sometimes twist during the longer exposures so as to produce a bad blur. I have had better results with reflected light than transmitted light. I am undecided as to whether a black background is superior to a white or not. Against the black background every speck of dust magnified ten fold produces a disagreeable effect.

I have also tried peristomes by transmitted light under a compound microscope. I squandered more than a dozen plates on the peristome of *Ceratodon* but its dark red color and density foiled my attempts to get anything but a silhouette.

The photographs themselves will tell you far more than I can as to my results.

If we go back a generation, say to the early '80's, we find up to this time most of the work published by American botanists was taxonomic. For some time before this, however, evidences of an awakening to other aspects of the science were evident and the next decade brought an extraordinary extension of botanical interest in other lines of work. Morphology, physiology and especially cytology began to demand attention.

This was the period also when the government began to consider seriously the application of botanical science to the great agricultural problems of the country. Most of the agricultural experiment stations, date from this time, and it is unnecessary to point out the great influence which these have had in directing the activities of so many of the ablest workers in the field of botany.

As one looks back over this period of some thirty five years one can not but be struck with the great increase in the number of botanical workers and the enormous number of publications recording the results of their work.

During the 70's and early 80's the opportunities for advanced work in botany, aside from purely taxonomic work, were very inadequate, even in our best universities, and students who were ambitious to avail themselves of the best instruction in botanical methods were almost perforce obliged to

¹ Presidential address of Professor Douglas H. Campbell, of Stanford University. Read before the Botanical Society of America at their dinner on December 30, 1914.

seek such instruction in Europe and especially in Germany. The last decade of the nineteenth century probably witnessed the largest emigration of American botanical students to Germany. These men brought back German methods and German ideas, and undoubtedly these influences were on the whole of immense service to the development of science in America. However, it has sometimes happened that these foreign fashions perhaps have been followed a little too slavishly and the work of some of our foreign students might be criticized as somewhat lacking in originality.

In point of equipment and opportunity for research it may be asserted safely that at the present time America can hold its own with any European country. It may be fairly asked, therefore, whether the accomplishment has been commensurate with the opportunities afforded.

There is no doubt that the quality as well as the quantity of work done in this country in the period in question has risen very much and one could select a very considerable part of the work which will bear comparison with the best of its kind done abroad. But it must be admitted that the great bulk of the work is of mediocre character. It is perhaps asking too much to expect that all or even a large part, of work of any kind should rise above the mediocre and it must be confessed that much of the work published in the United States can not be considered to be of first rate quality. However, it is probable that the average here might be raised without undue exertion.

It seems to me that perhaps the principal cause of this mediocrity is the tendency to follow whatever new fad may come into fashion instead of seeking for problems of one's own. We are, as a people, I think more prone to adopt new fashions than are the more conservative inhabitants

of the Old World. At any rate the past twenty or thirty years have seen the rise and decline of a good many botanical fashions each one of which was all important in its day.

Instead of a man's asking himself, 'What am I especially interested in and what can I do most advantageously,' the student usually through the advice of his instructor is put to work on the latest thing that has come from Germany or France sometimes before he has really mastered the fundamentals of the science. The results of such misdirected energy are naturally often unfortunate.

Another thing which may partly account for the rarity of work of the highest grade is the undue emphasis laid on the economic phases of the science. We Americans are preeminently a 'practical' people and our achievements in applied science are notorious. It is that we are incapable of recognizing the supreme importance of pure science that accounts for our comparatively poor showing in the way of contributions to the fundamentals of science, botanical or otherwise!

It is not however with the past history of our science that I wish to deal, but with its present tendencies and the prospects for its future development. One who has done his work and made his mistakes may be, perhaps permitted to criticize the present and make some suggestions for the future.

The equipment of our more important universities, as well as the liberal provision made by the government for scientific work, in connection with special private endowments for research work offer ample opportunity to the man who would devote his life to a scientific career.

Unfortunately the very perfection of the material equipment may cause us to attach undue importance to the mere apparatus of research, and to minimize the value of

the man who is to use this elaborate paraphernalia

I sometimes think that there is danger of our becoming slaves to our machinery. Life, alas! is too short to spend any unnecessary time in over-elaborate and complicated methods where simple and direct ones would answer every purpose. That much time is wasted in many laboratories through the employment of unnecessarily complicated methods, I firmly believe.

Another phase which I think has been overdone in America is the mania for standardizing everything. Elaborate systems of recording results are often so complicated as to be quite bewildering to the worker trained in old-fashioned ways, and he wonders sometimes at the very small output of work resulting from this imposing mass of machinery until he realizes that pretty much all of one's time must be consumed in keeping the machinery going.

While the standardization of science like that of automobiles may result in a good general average, and make for convenience and cheapness, it does not result in the highest type of work. The really big work in science must be done by men who are a law unto themselves. The highest type of original work can not be made to conform to fixed rules and regulations, and our American love of machinery and standardized methods as it seems to me, detrimental to the development of originality.

A problem that is always with us is the question of teaching versus research, and how far the two are compatible. I think we must all admit that the teacher, at least in the university, should be an investigator. Indeed it is hard to see how a teacher who himself is not engaged in research can expect to inspire in his students a desire to become investigators. The vexed question of the relative importance of teaching and research can hardly be an-

swered satisfactorily. Of course it is incumbent on every teacher to see that his teaching work is faithfully performed, but on the other hand the man who is capable of carrying on important researches and is willing to do so, has claims which every university worthy of the name is bound to respect.

So far as my own observation goes, it seems to me that the two are not incompatible, but I must also confess that it usually happens that whichever is the more congenial is likely to receive the greater attention.

I have very little faith in the assertion so often made that the time necessary for teaching is so great that no time is left for research. When one reckons up the time actually demanded of instructors in a well-equipped university and compares it with the time demanded of the average business or professional man, one must admit that the university professor has a very much greater amount of spare time at his disposal, which, if he really wishes to do so, he may devote to research. Too many of our teachers make work for themselves which is quite unnecessary and is a sad devourer of time, but which sometimes at any rate affords a convenient explanation of why they do not accomplish the great results which they would invariably do if only opportunity permitted. What a man wants to do most, he is pretty sure to accomplish, and if investigation is really what he is most interested in, he will find some means of doing it.

Of course, all men who occupy university chairs are not for that reason necessarily devotees of research, although I believe no man should be appointed to a university professorship who has not demonstrated his ability to advance knowledge in his chosen branch, and it should be expected

of him that his researches do not cease with his attainment of a professorship

The excuse is often offered that the professor is frequently subject to interruptions which interfere with research work. I notice, however, that such interruptions are quite as often as not the fault of the man himself, whose sociable disposition or inability to concentrate his attention as well as the fatal tendency to "putter," eat up the time which ought to be devoted to investigation and which if properly utilized, would soon show substantial results.

It is easy to find fault and criticize but when it comes to suggesting remedies for the future the problem is a difficult one. First of all perhaps, is getting hold of the right men and next, after getting them, to see that they make the most of their natural talents.

In these days of commercial ideals when the value of everything is gauged by what it will bring in the market, and especially in this country where the opportunities for easy money making are probably greater than anywhere else in this world, it is not strange that most of our young men become early infected with prevailing standards of values. One indeed must have a very strong love of science for itself to withstand the lure of the market place. To realize after years of hard work and expensive training that a man may in case he devotes himself to pure science have to serve for a lesser wage than is paid an expert bricklayer or carpenter, does not offer a very alluring prospect to most able and energetic young men. Nevertheless, if we are to develop men to do the highest type of work, we must in some way persuade them to take these chances.

Of course, before urging a young man to devote his life to a career at best pecuniarily far below what he might reasonably expect to earn in some other calling, we

should be very sure that our youth gives something more than a vague promise that he is likely to accomplish something really worth while in the branch he has chosen.

This is perhaps our most difficult task. We all have seen young men, bright and alert, who are immensely interested in their investigations just so long as you set them the problem and superintend the work, giving from time to time the necessary suggestions and encouragement. The question is, will they devise problems for themselves and carry them through without some one at their elbow to give them assistance when they come to a difficult place.

It is very hard to recognize the men who have this initiative and with it the perseverance and resourcefulness which mark the born investigator, and I believe there are born investigators just as truly as there are born poets and painters. You can cultivate the gift but you can not create it. How we are to discover our budding genius, however, and how we are to hold him when caught is another matter.

While undoubtedly there is much encouragement to be derived from the progress we have made during the past generation still we may learn a lesson from this which may help us to direct the work of the next generation so as to yield still better results.

I can not but feel that we very much need to have the importance of pure scientific work as an end in itself strongly insisted upon. This I believe is one of our hardest problems. In the face of the constant demand for men trained in technical lines and the indisputable importance of the many economic problems that confront us, it is hard to make the average hard headed young American see the beauty of science for its own sake. Our whole social system and modern trend of educational methods both tend to magnify the importance of

technical training when compared with education as an end itself. Every one can appreciate the value of making two blades of grass grow where before there was but one but the man who makes new ideas sprout is too apt to be looked upon as a harmless crank if indeed he is regarded at all.

It may be that a reform in our educational system is necessary. There are symptoms of a revolt against the extreme utilitarian views now current and it is possible that we may see a tendency to return in part at least to the older educational ideals. There can be no question that greater attention paid to the humanities would encourage a love for pure science as contrasted with applied science. The student who has had a sound training in literature, history, language and in the whole range of what we term the humanities will certainly have a broader outlook than the man whose training has been severely vocational. Such a student will be far more likely to appreciate the value of purely scientific work whose importance is to be measured in terms of intellectual satisfaction rather than in dollars and cents.

This then I believe is one way by which we may hope to recruit the ranks of investigators in the higher lines of science. Another benefit which would result from a more liberal training of the majority of our university students would be a far greater appreciation of the results of such scientific work by men who are not themselves scientists. It may be hoped after we pass beyond the era of great accumulation of wealth that there will be a greater appreciation of the less material results of the higher education. Just now it must be confessed this era does not appear to be imminent.

Having secured our special man, our next concern is to see that his efficiency is developed to the utmost. While of course it is essential that our man must first receive a

thorough training in the fundamentals of botany when the time comes for him to venture on original research every effort should be made to discover where his special ability lies and we should not try to force him to work along lines which are especially attractive to ourselves should he show a strong bent for work in some other direction. Here is where the danger of trying to follow the latest fashion comes in. It is very likely that our student may have a very lukewarm interest in Karyokinesis, Mendelism, Mutation or whatever the latest thing may be and an effort to force him into these subjects contrary to his own preference may result disastrously.

Of course in directing the work of students and we might also say in the selection of our own subjects for research we have to consider not only the importance of the topics but also—and this is very important—their practicability. I do not mean by this that we are to look for easy subjects but there are too many fascinating problems such for instance as the physical basis of hereditary transmission which from their very complexity seem almost hopeless of solution although we can make no end of ingenious hypotheses almost as many indeed as there are investigators. Such investigations are almost certain to be inconclusive and it is very questionable whether in many cases time devoted to these might not better have been dedicated to something more likely to yield more tangible results. In this connection it may not perhaps be impertinent to call attention to the very loose way in which much of the work now so popular on the problems of heredity is carried on. The tendencies to assume that the phenomena observed, in animals for example are also immediately applicable to plants and *vice versa* has led to a great deal of inaccurate thinking and writing.

It can hardly be said that any special

phase of botany is urgently demanding attention or is being noticeably neglected, nor can it be said that there is not abundant material awaiting the botanist in pretty much any line he may choose. One might, however, urge that our botanists seek out problems for themselves rather than borrow them from our foreign colleagues. There are surely enough original problems awaiting solution at home to keep our botanists fully occupied. The United States with its varied flora and extraordinary range of conditions gives the American botanists a great advantage over their European colleagues advantages which perhaps have not always been appreciated to their full extent.

The flora itself even the vascular plants is very far from being even fully catalogued and a wide field is open to the trained botanist for investigation of its distribution and relations. These problems of geographical distribution and of the origins of the different floral elements of our country are full of interest and deserve much more attention than has yet been given them. The man who will write a compendious and well balanced account of the distribution of the plants of the United States will deserve well of his botanical brethren.

While the vascular plants of this country have received much attention from the systematists and there are numerous excellent manuals dealing with them the lower plants have not perhaps received a corresponding amount of attention. There is still room for handbooks dealing with most of the lower groups of plants which can be used by the student to identify them. Perhaps more than anything else a manual of the marine algae is needed.

Passing to another phase of taxonomy, attention may be called to the need for a radical revision of the classification of the seed plants. Perhaps the time is not yet

ripe for this but it is abundantly clear that the classification now in use is very far from indicating all the real relations. Among the Angiospermous plants for instance I believe it will soon be generally admitted that the present division into Monocotyledons and Dicotyledons is a more or less artificial one. It is very necessary that the lower and more generalized families of both Monocotyledons and Dicotyledons should be studied critically with a view to determining the relations of these to the more specialized ones. Any one who has done any practical work in this direction realizes the difficulties of the problem but I do not believe these difficulties are insuperable. The work calls for much laborious research often ending in negative results but from my own experience I believe that finally we shall arrive in this way at a much clearer understanding of the relations existing between the families of both Monocotyledons and Dicotyledons than we now possess and that we may hope for a final clearing up of the relations of these two groups to each other.

It is to be hoped that our students of fossil plants by patient searching may finally bring to light material which will do for the Angiospermous plants what has been done by the brilliant researches of the past few years on the geological history of the Pteridophytes and Gymnosperms.

Just at present there is great interest taken in the question of the so called 'mutations' and much inquiry as to their real meaning and their bearing upon the origin of species. One writer—Lotay—going so far as to claim that all new species originate as hybrids a hypothesis which few would be willing to accept without many reservations although there is no question that what are apparently good species have so originated in nature. This study of natural hybrids has been but little pursued in

this country and offers a very fertile field for investigation

Another phase of the origin of new forms is one which opens up a large field for research and ought to yield valuable results. This is the study of the changes in naturalized plants. In all the older parts of this country there are very many naturalized plants, principally weeds, which have been brought from abroad and are mostly of European origin. Many of these must have been introduced very early in the settlement of the country, so that some of them have been subjected to new environmental conditions for a period of nearly three hundred years. This ought in some cases to have resulted in perceptible changes, especially as these plants have not been subjected to the same keen struggle for existence which exists in their native habitat, and sometimes at least, grow in their new home with a vigor that one does not see in their native land. It seems to me that a careful study of some of these introduced weeds in their new environment and a comparison with the same species at home ought to furnish some valuable data in regard to some of the factors concerned in the origin of new species.

Finally, a critical study of variation in our native plants and the conditions associated with these should be of value in this same connection. In California, especially, the variations within the species are sometimes very marked and make the separation of species extremely difficult. While some of these variations can be explained by the difference in the conditions under which they grow, this is not always the case, and undoubtedly there are marked individual variations which can not be so explained. Such studies made upon plants in their natural surroundings should be more valuable than those based on plants growing under artificial conditions.

What then is the present outlook for botany in America? Facilities are certainly not wanting, equipment and aids to research are equal to those anywhere, and there surely is no lack of material and of problems awaiting the right men.

Are we going to attract to our profession men of such capacity that the next generation is to win results commensurate with the opportunities furnished by this rich and generous country? Let us hope that we shall soon become educated sufficiently to appreciate the labors of the scientist apart from their immediate pecuniary value and that the men who are endeavoring to extend the boundaries of knowledge shall receive adequate recognition. When this is true, I think we may count on adding able recruits to our forces, and these botanists of a later day will be no mere adopters of ideas borrowed from foreign sources but will be original investigators in the truest sense of the word. These men will appreciate the wealth of material lying immediately to hand and the important problems of American botany will receive full attention. Of course, I would not urge narrow provincialism in the choice of subjects—that is as far as possible from my thought—but I mean that the investigator should seek inspiration from the sources to which he has immediate access and not get it second hand no matter how illustrious the source of inspiration may be.

Only by this reliance upon himself by the investigator can work of the highest kind be accomplished.

DOUGLAS H. CAMPBELL

THE CARNEGIE INSTITUTION OF WASHINGTON¹

Nearly thirteen years have now elapsed since the foundation of the institution in

¹ From the report of the president, Dr. R. S. Woodward, for the year ending October 31, 1914.

1902 A majority of the larger departments of research established under the direct auspices of the institution have been effectively at work for about a decade while investigations of numerous individuals primarily connected mostly with academic and other organizations have been promoted for an approximately equal period of time Thus although this must be regarded as a very short interval in the career of an establishment whose history should be measured by centuries it has been long enough to afford surprisingly large opportunities for the development of ideas and ideals concerning the conduct of research In addition to the necessarily limited number of investigations actually undertaken by the institution it has entertained proposals for research in nearly every imaginable field of abstract thought and of applied knowledge If under these circumstances the institution has not learned something of the wisdom which is said to arise from experience lack of abundance thereof can not be properly assigned as a reason for so obvious a lapse An adequate account of this very extensive and very complex experience which while overloaded with the manifest and the impracticable is yet rich in applicable instruction may not be attempted here an appropriate objective treatment would require a separate volume and another author But it may be useful to contemporaries to set down here a few salient propositions which like those stated formally in my report for 1912 have been amply verified

Thus as regards research and the conditions favorable thereto it is in evidence—

1 That it is inimical to progress to look upon research as akin to occultism and especially inimical to mistake able investigators for abnormal men Successful research requires neither any peculiar conformity nor any peculiar deformity of mind It requires rather peculiar normality and unusual patience and industry

2 That fruitful research entails in general prolonged and arduous if not exhausting labor for which all of the investigator's time is none too much Little productive work in this line may be expected from those who are ab-

sorbingly preoccupied with other affairs Herein as well as in other vocations it is difficult to serve two or more exacting masters

3 That those most likely to produce important results in research are those who have already proved capacity for effectiveness therein and who are at the same time able to devote the bulk of their energies thereto In general men are not qualified for the responsibilities of research until they have completed independently and published several worthy investigations

4 That research like architecture and engineering is increasingly effective in proportion as it is carefully planned and executed in accordance with definite programs A characteristic defect of a large majority of the proposals for research submitted to the institution is a lack of tangible specifications Estimates especially of time and funds essential to carry out such proposals are almost always too small Those commonly made even by skilled investigators may be on the average safely doubled

5 That in spite of the most painstaking foresight research tends to expand more rapidly and hence to demand a more rapid increase of resources than most other realms of endeavor Its unexpected developments are often more important than its anticipated results and new lines of inquiry often become more urgent than those carefully prearranged for pursuit

6 That it is much easier in general to do effective work of research in the older fields of inquiry than in the newer ones It is especially difficult to enter those fields in which there is as yet no consensus of opinion concerning what may be investigated and what criteria may be followed In some of the older fields however like the so called humanities, for example there is at present no such consensus of opinion if one may judge from the large mass of expert but hopelessly conflicting testimony furnished to the institution by its correspondents In such fields it appears now practicable to proceed only in a somewhat arbitrary fashion accomplishing here and there good pieces of work regardless of divided opinions or even in opposition to expert

advice, in illustration of which may be cited the institution's publications of the "Old Yellow Book" and the "Arthurian Romances"

The larger departments of research of the institution are now so well established and so distinctive in their several fields that they might be regarded as so many separate organizations except for their dependence on the institution for financial support. They are not uncommonly considered in fact as independent organizations while several of them have been mistaken for the institution as a whole. Such misapprehensions are inevitable, but their existence suggests a question well worthy of reflection, namely whether it may not be well in the course of time, for some, or all, of these departments to sever connections with the institution if they should have the good fortune to receive adequate separate endowments. The only concern the institution need have in such circumstances is that of securing to these departments the most favorable conditions for effective work. If this object may be best attained by independent foundations, or by affiliation with other organizations, no obstacle should be raised against such action.

But quite apart from these hypothetical considerations, the existing relations of these departments to one another and to the institution as a whole secure to them a degree of autonomy which could hardly be surpassed under other auspices. The liberties of action, thus designedly and freely conceded, imply corresponding responsibilities not only in departmental administration but also in departmental exposition, whether by summary annual reports or by elaborate monographs. Accordingly, and in conformity with other reasons referred to in previous reports, the following paragraphs aim to give brief indications only of departmental progress, reference being made for instructive details to the reports of the several directors in the current year book.

In connection with the subject of departmental researches particularly, the question is often asked "How can the 'practical results' attained be popularized and thus rendered available to the masses of mankind?" This is a question too large and too difficult for adequate discussion here, but it is one merit-

ing studious contemplation in the interests of our successors. It may be recalled that a hopeful paragraph was devoted to this topic in my first annual report, of 1905 but subsequent experience does not seem to justify the optimism entertained at that time. It is now plain, indeed, that while as a matter of fact truth is not only stranger but much more important than fiction, contemporary media for the dissemination of the sensational and the intangible are far more numerous and potent than the media for the dissemination of the demonstrable and hence permanent additions to knowledge. And it is equally plain that until there is an increased demand for less of the spectacular and for more of the real, both from journalists and from their readers, there can be little improvement in the popularization of discoveries and advances through such media. In the meantime, the increasing value of these researches, now everywhere recognized by scholars, may presently justify the engagement of an expert to popularize not simply the "practical results" but to furnish also what is in general more important, to wit a clear and concise account of the principles and the methods by which such results are derived.

DEPARTMENT OF BOTANICAL RESEARCH

Although the greater part of the work of this department is carried on at its principal laboratory at Tucson, Arizona, it is essential to a comprehensive study of desert plant life to explore distant as well as adjacent arid regions. Thus having published during the past year the results of an elaborate investigation of the region of the Salton Sea, the department is now among many other activities, turning attention to similar desert basins, of which there are several in the western states that have been studied hitherto in their geological rather than botanical aspects. These researches are entailing also many applications of the allied physical sciences not heretofore invoked to any marked extent in aid of botanical science. Hence there results properly a diversity of work quite beyond the implications of botany in the earlier, but now quite too narrow, sense of the word.

In addition to the work carried on by members of the departmental staff various investigations have been pursued by about twenty collaborators several of whom have been in temporary residence at the Desert Laboratory. Among the more noteworthy publications emanating from the department during the year may be cited along with the monograph on the Salton Sea referred to above the instructive volume by Dr Forrest Shreve of the departmental staff on *A Montane Rain Forest* (Publication 199 of the institution). Favorable progress has been made by Messrs Britton and Rose research associates of the department in their elaborate investigation of the distribution and relationships of the Cactaceæ. The facilities of the Desert Laboratory have been enlarged during the year by the completion and equipment of a specially designed small building for studies in phytochemistry which has been proved to play a highly significant role in desert life.

DEPARTMENT OF ECONOMICS AND SOCIOLOGY

The work of this department has been confined in recent years to the preparation of divisional monographs as explained in previous reports. Dr Victor S. Clark in charge of the division of manufactures has been able to devote his time exclusively to this work and has been furnished office quarters for this purpose in the administration building at Washington. Other heads of divisions have been able to give half or less time to their divisional work which is thus progressing somewhat more favorably than hitherto. It is hoped therefore that some of the monographs under way may be ready for publication during the coming year. Of the comprehensive

Index of Economic Material in the Documents of the States" projected by the department and prepared under the direction of Miss A. R. Hasse the volume for New Jersey is now in press. Volumes of this index for eleven different states have already been issued.

DEPARTMENT OF EXPERIMENTAL EVOLUTION

The observational statistical and physical methods applied by this department are constantly adding to the sum of facts and of in-

ductions essential to advances in biological knowledge. The range of application extends from the lowest organisms like fungi up to the highest as typified in the race to which the investigators themselves belong. Thus during the past year observations and experiments have been made on mucous plants, pigeons, poultry and seeds while the director has continued his fruitful statistical studies in the relatively new field of departures from normality in mankind. The variety of agencies employed in this wide range of inquiry now includes a permanent staff of about twenty members and a physical equipment enlarged during the year by the completion of an additional laboratory and a power house. Early in the year the facilities of the department were increased by the successful transfer from Chicago to Cold Spring Harbor of the remarkable collection of pedigreed pigeons recently acquired by the institution from the estate of Professor C. O. Whitman.

Among the numerous researches of the year to which attention is given in the departmental report there may be cited as of special interest those of the director in human heredity those of Dr Blakeslee and Dr Gortner on mucous plants those of Dr Riddle on the Whitman pigeons those of Dr Harris on the characteristics of seeds and those in cytology by Mr Metz. It is of particular interest to note that in all of these definite measurable relations are anticipated as attainable just as such relations are now assumed to be attainable in the older physical sciences. The director accepted an invitation from the New Zealand government and from the British Association for the Advancement of Science to take part in a series of scientific conferences held in Australasia during the past summer. Dr Shull of the departmental staff spent the year in Berlin preparing his account of the horticultural work of Luther Burbank. The department expresses regret at the loss from its staff of Dr R. A. Gortner who has resigned to accept a position in the University of Minnesota. His abilities as an investigator and his capacity for effective cooperation won high regard from his colleagues.

GEOPHYSICAL LABORATORY

An instructive example of the favorable progress which may be confidently expected in any field of research when entered by an adequately manned and equipped department devoted solely thereto is afforded by the experience of the geophysical laboratory. In less than a decade this establishment has not only accomplished the formidable task of constructing the necessary apparatus and of preparing many of the pure minerals concerned but has already begun the processes of analysis and synthesis which are leading to extensive additions to our knowledge of rock and mineral formations found in the earth's crust. In illustration of these processes the director's report cites the mineral system dependent on the elements lime, alumina and silica which elements include in their multifarious possible combinations the well known but hitherto little understood compound called Portland cement whose properties have been determined as an incident to the general problem presented by this system.

Among the numerous problems under investigation at the laboratory one of immediate economic as well as of great theoretical interest may be cited here by reason especially of the fact that funds for its execution have been supplied by industrial sources. This is the problem of the secondary enrichment of copper ores and the success attained in its treatment demonstrates the practicability of advantageous cooperation between the laboratory and industrial organizations without restriction to scientific procedure and publicity. The section of the director's report devoted to this subject should be of special interest to geologists and to mining engineers as well as to copper mining industries. A more comprehensive idea of the productive activities of the laboratory may be gained by a glance at the section of the director's report in which he gives brief abstracts of the publications which have emanated from members of the staff during the year. These publications embrace forty nine titles of papers which have appeared in current journals or are in

press many of them having been published in German as well as in English.

DEPARTMENT OF HISTORICAL RESEARCH

The investigations of the department of historical research have proceeded effectively in accordance with the plans outlined by the director in his reports published in previous year books. In addition to the members of the permanent staff several collaborators have taken part in these investigations which have required explorations of historical archives in England, Scotland, France, Spain, Holland, Russia and Switzerland. Departmental plans for pursuit of peaceful studies in foreign archives however have suffered a serious check in the onset of the European war and much work well started or approaching completion must now await developments from the pending conflict.

Two bulky volumes of guides to the sources of American history have issued from the department during the year as Publications 90a and 90b of the institution. These are respectively *Guide to the Materials for American History to 1783* in the Public Record Office of Great Britain and *Guide to the Materials in London Archives for the History of the United States since 1783*. It had been anticipated that a similar guide to the data on American history in the archives and libraries of Paris in preparation under the charge of Mr. Leland of the departmental staff would be completed before the end of the present calendar year but the exigencies of the war have required the suspension of this work at Paris and the return of Mr. Leland to the departmental office in Washington. Similarly work undertaken for the department in Holland by Professor William I. Hull and in Spain by Mr. Francis S. Philbrick had to be suspended. On the other hand researches under way in Great Britain and in Russia have suffered little interruption. Work at the home office has proceeded without discontinuity. The director calls attention particularly to progress made in work on the projected *Atlas of the Historical Geography of the United States*. Two divisions of this

atlas, illustrating respectively the history of presidential elections and the records of votes cast in the House of Representatives for or against certain typical measures of legislation, extending from 1789 to 1914, are already well advanced

DEPARTMENT OF MARINE BIOLOGY

In accordance with plans recommended by the director of the department of marine biology and approved by the trustees in 1912 an expedition to Torres Straits, Australia a region already known to be remarkable for abundance and variety of marine life, was undertaken in the latter part of the preceding fiscal year. Early in September, 1913, the director and six collaborators arrived at Thursday Island in the Straits, expecting to use this relatively accessible island as a base of explorations, but it was soon found advantageous to locate on Maer Island, one of the Murray group, about 120 miles east northeast, and near to the outer limit of Great Barrier Reef. Here a temporary laboratory was set up in the local courthouse and jail, generously placed at Dr. Mayer's disposal by the British authorities. The region proved to be one rich in coral reefs and in marine fauna for the work contemplated. Observations and experiments securing gratifying results were carried out during the spring months (in the southern hemisphere) of September and October, 1913. In addition to the critical data secured by Dr. Mayer with respect to the corals about Maer Island, for comparison especially with corresponding data from the corals of Florida waters, observations and materials for important contributions to zoology were collected by each of his collaborators. One report, by Dr. H. L. Clark, is now in process of publication and is remarkable for the new species of echinoderms described and for the admirable drawings of these forms made from life by Mr. E. M. Grosse, of Sydney, Australia, who accompanied the expedition.

On returning to America from the southern hemisphere, the director was engaged, during April and May, in two minor expeditions with

the departmental vessel *Anton Dohrn*. The first of these was in aid of the researches of Dr. Paul Bartsch on cerions, and required a cruise along the Florida Keys from Miami to Tortugas and return. The second expedition was in aid especially of Dr. T. W. Vaughan, long associated with the department in studies of corals and related deposits and required a cruise from Miami, Florida to the Bahamas and return. On June 9, 1914, work was resumed at the Tortugas Laboratory and continued until July 30. In all fifteen collaborators during the year have availed themselves of the facilities afforded by the department. Brief accounts of their varied researches may be found in the director's report in the current year book while detailed accounts may be expected in due time in the departmental contributions.

Attention is invited to an interesting section of the director's report devoted to a summary of the work accomplished by the department during the first decade of its existence. This section is instructive in showing that a decade is the smallest convenient unit of time for adequate estimation of the activities of such an establishment. It appears that during this decade 49 investigators have made use of the Tortugas laboratory, 28 of these having returned two or more times, making a total of 108 visits to this relatively inaccessible center of research. Of the publications emanating from the department, 60 have been published by the institution while upwards of 40 have been published under other auspices, the institution has issued 2,551 printed pages and 269 plates exclusive of annual reports appearing in the year books.

DEPARTMENT OF MERIDIAN ASTROMETRY

The activities of the department of meridian astrometry are concentrated on the derivation of stellar positions for the comprehensive catalogue in preparation, on supplementary measurements of stellar coordinates with the meridian circle of the Dudley Observatory, and on investigations of residual stellar motions. The latter have now become the most important element in the definition

of stellar positions by reason of the extraordinary recent progress in sidereal astronomy to which the department has contributed in large degree. Thus along with the formidable computations required by the large mass of observations made by the department at San Luis Argentina researches are simultaneously continued on the problems of the star drift including the speed and direction of motion of our solar system. In the meantime the catalogue is progressing favorably and some portions of the observatory list of miscellaneous stars are approaching completion although cloudiness during the past two winters has interfered with this part of the departmental program. In the meantime also the manuscript of the zone catalogue of stars whose positions were measured at the observatory during the years 1896 to 1900 is undergoing the final process of comparison and checking preparatory to publication.

THE NUTRITION LABORATORY

The anticipations of a specially favorable environment which were entertained when the nutrition laboratory was located in Boston near the Harvard Medical School and near several existing and projected hospitals are now fully realized and it would appear that the laboratory is reciprocally advantageous to the several establishments with which it is in immediate contact. Indeed with this as with all other departments of research founded by the institution the only fears to be seriously entertained are those due to increasing capacity for usefulness and scientific progress since such capacity tends quite properly to grow faster than the institutions in come warrants.

The completion of adjacent buildings and streets has permitted bringing the grounds of the laboratory into harmony with its physical surroundings. Improvements have been made in the laboratory itself and several additions to equipment have been installed. These latter include new respiration apparatus for studies of metabolism in muscular work of men and of small animals, a reconstruction of an earlier form of bed calorimeter and addi-

tional apparatus for photo electric registration of physiological action in subjects under observation, whether near by or at a distance.

As indicated in previous reports the laboratory and its work are subjects of international as well as national interest and many cooperative efforts are arising therefrom. Thus Dr Hans Murschhauser of the Kinderklinik in Dusseldorf and Dr Carl Tigerstedt of Helsingfors have each spent several months at the laboratory during the year as research associates while M. Lucien Bull as assistant director of the Institut Marey in Paris spent several weeks at the laboratory studying its apparatus and methods. The researches in progress by the laboratory staff are briefly summarized by the director under twenty different heads in his annual report to which reference must be made for personal and technical details. Abstracts are given also in his report of the publications issued during the year or now in press. Of these attention may be called particularly to *The Gaseous Metabolism of Infants with Special Reference to its Relation to Pulse rate and Muscular Activity* by Francis G. Benedict and Fritz B. Talbot (Publication No. 201) and to *A Study of Prolonged Fasting* by Francis G. Benedict (in press as Publication No. 203).

DEPARTMENT OF TERRESTRIAL MAGNETISM

The extensive operations of the department of terrestrial magnetism on the oceans and in foreign countries have been adequately supplemented during the year by the new departmental laboratory whose completion and occupation took place nearly simultaneously with the beginning of the second decade of the department's existence. This laboratory and its site provide greatly enlarged facilities for research as well as unsurpassed quarters for the resident departmental staff. This site (of 7.4 acres) is well protected on all sides from possible objectionable elements while the laboratory is an exceptionally well lighted fire proof building with 44 rooms and many specially designed adjuncts. Attention may be invited particularly to the relatively low

cost (22 cents per cubic foot) of this building, and to the reasons why it, like the geophysical laboratory and the nutrition laboratory, has been economically built. These reasons are found mainly in deliberate preparation of preliminary programs in carefully drawn plans and specifications by competent architects and in responsible superintendence of construction.

Near the end of the preceding fiscal year the non magnetic ship *Carnegie* returned to New York City, where she underwent such extensive repairs as are always required by wooden vessels after long cruises in tropical waters. After refitting she left New York, June 8, 1914, for a cruise in the North Atlantic. In this the third of her expeditions, she traversed about 10 600 miles making a first stop at Hammerfest Norway July 3 reaching the high latitude $79^{\circ} 52'$ off the northwest coast of Spitzbergen, touching at Reykjavik, Iceland, August 24 and returning to the base station at Greenport Long Island October 9 and to Brooklyn, New York, October 21. During this cruise the *Carnegie* was in command of Mr J P Ault. She is now refitting for a longer cruise during 1915-1916, in southern latitudes (50° to 75°), where magnetic observations require supplementing.

An attempt at an ocean expedition into Hudson Bay was made under the charge of Mr W J Peters during the past summer, but on account of unusual obstacles from ice this proved only partly successful. Entrance into the bay with the auxiliary schooner, *George B Cluett* chartered for this purpose from the Grenfell Association, was blocked until September 2, leaving less than a month's time available for surveys.

Determinations of magnetic elements on land have been continued in six parts of Africa, in as many states of South America, and in Australia, bringing the surveys of all these continental areas to a well advanced stage.

Attention may be called to an interesting summary given by the director in his current report of work accomplished by the department during the past decade, as well as to accounts of the investigations now in progress

under the department at its laboratory, of the operations on land and sea, and of the departmental publications of the year. Of these latter, Volume II of the "Researches of the Department of Terrestrial Magnetism," under the subtitle "Land Magnetic Observations, 1911 to 1913 and Reports on Special Researches," by L A Bauer and J A Fleming, is now in press.

THE SOLAR OBSERVATORY

With the end of the current year the Mount Wilson Solar Observatory, like most other departments of the institution will have completed a first decade of its history. Quite appropriately, this establishment was founded at an epoch of maximum sun spots and a marked increase in solar activity during the past year furnishes similarly auspicious conditions for entrance into a second decade of research. But much more auspicious conditions are found in the extensive experience and in the effective equipment acquired along with the capital progress attained during this first decade. The most sanguine astronomer would have hesitated at the earlier epoch to predict that these latter conditions could be realized at the present epoch. Herein also is found a signal illustration of the superior effectiveness of establishments primarily designed for and exclusively devoted to research as compared with establishments in which research is a matter of secondary interest.

The work of the observatory for the year is much too extensive to permit of adequate summary here. But this is unnecessary, since the director's report, in addition to detailed accounts of observations, investigations and construction, gives a condensed abstract of the salient results arrived at. These results are briefly and clearly stated in 59 paragraphs. They refer to correspondingly numerous measurements, calculations and inductions made in studies of the sun and other stellar bodies whose characteristic properties are now stimulating extraordinary advances in cosmic physics.

Progress in construction of the 100 inch telescope has been made as rapidly as could be

expected in so formidable an undertaking. The delicate optical task of shaping the 100 inch mirror has been brought successfully by Mr Ritchey to the stage of sphericity which precedes the final state of parabolization. The difficulties due to distortion of the mass of the disk referred to in previous reports have been overcome and other obstacles due to temperature inequalities in the optical room are likewise yielding to appropriate precautions. In the meantime the foundations for this telescope have been completed and the mounting and dome are expected to be ready for erection during the coming year. Several smaller parts and accessories for this instrument requiring special exactness are under construction at the shops of the observatory in Pasadena. Many additions and improvements in the apparatus already installed at the observatory have been made. The 60 foot tower telescope particularly which was originally cheaply constructed in order to test the possible advantages of such a departure from earlier forms of telescopes has been put in a state of efficiency comparable with that of the 150 foot tower telescope leaving the latter free for the uses to which it is specially devoted. In these general improvements much attention has been given to rendering the plant on Mount Wilson more nearly fire proof. The mountain road has been repaired widened and strengthened in many parts in anticipation of the heavy traffic essential to transportation of the 100 inch telescope to its destination.

WORK OF RESEARCH ASSOCIATES AND COLLABORATORS

The variety and extent of the work carried on by research associates and collaborators has led to the widely spread but erroneous notion that the institution has entered or is able to enter all possible fields of investigation and that an expert can be supplied offhand for immediate consideration of any question which the world may submit. But while such comprehensive capacity is obviously unattainable by finite means or by any single establishment, the scope and ramifications of this work are such as to defy adequate condensation and

exposition within the limits of an administrative report. To understand this branch of the institution's activities one must at least read the titles of the reports and the publications which appear in the current year book and know something of the contributing authors and their environments. Summarily it may be stated that more than a hundred individuals have been engaged in these activities during the past year and that their work embraces a range of about thirty different subjects of research. Although attempts to draw lines of distinction between adjacent fields of advancing knowledge are alike futile and inimical to progress it may be of interest to note with respect to these subjects that if they be classified under the two categories of descriptive sciences and mathematico-physical sciences respectively they will be found to be about evenly divided. It may be noted also that in this work the so-called humanities represent no small share since researches have been promoted during the past year in Roman archeology in Central American archeology, in Roman paleography in history in law in linguistics and in several branches of literature. But in all this latter work the object has been not to fix nor to accept categories nor to determine shares but to produce results of permanent value.

Referring to the individual reports and to the bibliographic lists in the current year book for accounts of the investigations and of the publications of the year in this highly diversified branch of the institution's work it must suffice here to cite a few salient facts indicative of progress. Thus Dr Van Deman in her studies of Roman archeology has developed criteria for determining epochs and periods in the evolution of Roman construction and hence in the evolution of Roman history. In the allied field of Roman paleography Dr Loew has published through the Clarendon Press Oxford a volume of researches under the title *The Beneventan Script. A History of the South Italian Minuscule*. The extensive researches in embryology carried on under the direction of Professor Mall with the collaboration of a number of associates, have

proved highly productive, as shown by the publications issued and in press. Similarly, attention may be called to the fruitful studies of Dr. Osborne and Professor Mendel, which promise to throw important light on the intricate physico-chemical processes of animal nutrition and growth. The older sciences of chemistry and physics have made not less important progress through the contributions of a dozen associates and many more collaborators. A very noteworthy advance has been secured in meteorology by Professor Bjerknes through the international adoption of his methods and units for expressing meteorological data. Beginning with this calendar year and continuing up to the onset of the European war the United States Weather Bureau issued daily weather maps of the whole northern hemisphere in conformity with these new methods and units greatly to the advantage of theoretical and applied meteorology. The comprehensive and always highly suggestive expositions in geology and in cosmogony for which Professor Chamberlin has long been distinguished have stimulated his colleagues. Professors Michelson, Gale and Moulton to the production of a capital contribution to geophysics in an ingenious and conclusive proof that the rigidity of the earth is about the same as that of steel. And finally, in illustration of the ease of passage from one field to another in this complex miscellany of independent researches, there may be cited the concordances of the earlier poet Horace and the later poet Spenser, now in press as numbers 202 and 189, respectively of the institution's series of publications.

FINANCIAL RECORDS

The following list shows the departments of investigation to which the larger grants were made by the trustees at their last annual meeting and the amounts allotted from these grants by the executive committee during the year.

Department of Botanical Research	\$42,140
Department of Economics and Sociology	5,000
Department of Experimental Evolution	63,479
Geophysical Laboratory	85,500

Department of Historical Research	31,100
Department of Marine Biology	19,150
Department of Meridian Astrometry	25,180
Nutritox Laboratory	45,798
Division of Publications (office expenses)	10,000
Solar Observatory	220,892
Department of Terrestrial Magnetism	157,406
Researches in Embryology	26,900
Total	\$732,545

THE BUREAU OF MINES

In his annual report to the secretary of the interior, Director Joseph A. Holmes, of the United States Bureau of Mines, states that excellent progress has been made during the past fiscal year in the investigations of the explosibility of coal dust at the experimental mine near Bruceton, Pa. These investigations included a careful examination into the inflammability of coal dust collected from hundreds of mines in different coal fields and a systematic study of the possibility of coal-mine explosions starting from the improper use of explosives or the use of improper explosives or from electric sparks, miners' lamps, mine fires or other agencies.

Probably the most important feature of the year's work was the development of four types of explosion stopping devices in which rock dust is used as follows: Box barriers, concentrated barriers, ventilating door barriers and ventilation stopping barriers. The barriers were tested in strong and weak explosions and were effective in preventing propagation of flame beyond them. After being placed in a mine they are easily inspected and require little attention. Demonstrations before mining men led to inquiries from a number of companies with a view to the erection of the devices in mines. The results of the tests at the experimental mines have shown the value of watering.

Four great explosions occurred during the year, as follows: One in the Stag Canyon mine, at Dawson, N. Mex., October 22, 1913, resulting in the death of 263 men, one at Acton, Ala., November 18, 1913, in which 24 men were killed, one at the Vulcan mine, New

Castle, Colo., December 16, 1913, in which 37 men were killed, and one at Eccles, W. Va., April 28, 1914, in which 181 lives were lost. The general ventilation in most of the mines involved in explosions was good, but the defect in certain mines was in permitting the local accumulation of gas through not bratticing up to the face of gaseous entries or working places. One of the great disasters was probably caused by the use of dynamite for blasting, and by disobedience in firing a shot or shots when miners were in the mine, in spite of the fact that an outside shot firing system had been installed.

Other lesser disasters occurred during the year. Many shot firers lost their lives in the Pittsburgh, Kans. district, and in Oklahoma, Indiana and Iowa. Although the system of employing shot firers to fire the shots when all others are out of the mine lessens the number of deaths, yet in many districts the methods of shot firing employed are still so extremely hazardous that only the most reckless men are willing to act as shot firers. In any mine in which this system is used there seems to be no good reason why shot firing from without the mine by electrical means should not be employed, at least if permissible explosives are not used.

Director Holmes strongly urges the purchase by the government of the grounds on which the experimental mine is situated. He declares that the Bureau of Mines should own these grounds, now merely leased, in order to safeguard the large expenditure already made in developing the mine thereon and equipping it with expensive appliances.

Looking to the future, the director observes that, despite the progress made in ascertaining the nature of mine explosions and in devising methods of prevention, they still continue to occur, and it is to be feared that complete prevention will be difficult, owing to the inherent difficulty of eliminating errors of observation, judgment, or understanding from among miners or mine officials. Thus, one of the shocking disasters of the past year was brought about because of one man's willing-

ness to risk the sacrifice of not only his own life, but the lives of many others in order to gain a few tons of coal. It is difficult to meet such a case, and yet with the progress that is being made in the methods of preventing or limiting explosions, it is certain that hereafter in a well protected mine properly cared for there will be much less danger of a widespread explosion.

THE UNIVERSITY OF CINCINNATI BUREAU OF CITY TESTS

The Bureau of City Tests aids the city in two ways. It helps the government to purchase the best materials, by examining the dealers' samples, and, by making further tests from time to time, enables it to receive supplies of good quality throughout the year.

Cincinnati is one of the first large cities to purchase coal under competitive bidding in accordance with well drawn specifications. All its purchases are made on the British thermal unit basis. In submitting bids, dealers guarantee a certain number of heat units per pound and a certain percentage of ash. The cost per heat unit in the various bids is then calculated and the contracts awarded. All moisture in excess of the amount normally present is deducted from the tonnage delivered. The result of this new system has been the receiving of a good uniform grade of coal.

The bureau tested the 450 or more carloads of cement used during the year, for various city improvements. In spite of the fact that only standard brands which have proved dependable are used, 11 carloads of cement of poor quality were rejected. The steel employed to reinforce concrete work is tested physically, and of this but one questionable sample was received.

By testing fire hose, the city saved \$11 000 on the contract of 1913, and about the same amount on that of 1914. The bureau analyzes samples without any knowledge of the bidders' prices, and contracts are let on a quality basis to the lowest bidder whose product conforms to the standard underwriters' specifications. The satisfactory performance

of the hose under heavy duty has shown the value of these examinations.

In the case of lubricating oils also, the contracts are let to the lowest bidder whose oil conforms to the specifications of the bureau. At one time, 26 samples of oil were rejected, and it was necessary to advertise for new bids. The second set of samples were practically all up to the requirements.

The 1164 samples examined during the past year can not all be mentioned, but here are a few that were rejected as inferior paint, with over 20 per cent gasoline, sand dirty not well graded and unsuitable, anti freezing compound guaranteed free from calcium chloride, yet found on analysis to be composed entirely of calcium chloride and water, marble cleaner, high in price, and consisting entirely of washing soda, woolen blankets supposed to contain not more than 15 per cent of cotton, yet shown on analysis to have 30 per cent, and sulphuric acid, containing such a high percentage of iron that it would have ruined the expensive storage batteries of the fire alarm telegraph system.

The services of the bureau are, for the most part accepted in a cooperative spirit by dealers and manufacturers. Its reports are frequently the first analyses the dealers have seen of their products, and they have shown much interest in the results and have tried to meet the specifications. The work of the bureau has increased 80 per cent since last year. The city departments are rapidly taking advantage of the laboratory, and the coming year will undoubtedly show a big increase in the variety, as well as in the volume of the work submitted.

THE RETIREMENT OF CHARLES HORTON PECK

The regents of the University of the State of New York on the retirement of Charles H. Peck from the position of New York State botanist have adopted the following minute:

The service rendered to the state by Charles Horton Peck, DSc, who has just retired from his position as state botanist has been extraordinary in its fidelity assiduity and productiveness. Dr

Peck entered the staff of the State Museum as botanist in 1867, and from that date to the present, his service has been continuous—a period of 48 years. In 1883 the position of state botanist was created and he has been its only incumbent.

The nearly half century of his scientific activity became an epoch in the science of botany in America, by virtue of the extensive contributions which he made, not alone to the knowledge of the flora of New York but specially through his almost pioneer investigations among the fungi. His researches in this field vastly increased the sum of knowledge and established an orderly and rational classification so that his published papers issued in the reports of the state museum, are indispensable to any student of these forms of life. The number of species discovered and described by him are counted by thousands and the additions made through his efforts to the state herbarium are so extensive that this collection of plants is to day among the largest on the continent and of great scientific worth. By common consent of his colleagues Dr Peck has long been recognized as the ultimate authority in mycology—the field of his special labors.

In view of these services whose value to the state can not be briefly estimated or readily expressed, the regents take this occasion to record, with their regret that the exactions of time have impelled him to retire from the service of the university and the state, their congratulations to Dr Peck upon a life well rounded and a work well done, with their assurance of continued interest and deep regard for his welfare during the years that may remain.

SCIENTIFIC NOTES AND NEWS

THE annual meeting of the Wesleyan University Club of New York City, on January 28 was in honor of the fiftieth anniversary of the graduation of Dr William North Rice, professor of geology.

DR ROBERT H. RICHARDS, professor emeritus in the Massachusetts Institute of Technology, has been awarded the gold medal of the Mining and Metallurgical Society of America in recognition of his services in the advancement of the art of ore dressing.

PROFESSOR ISAIAH BOWMAN, now in charge of geography at Yale University, will at the end of the current academic year on about

July 1 remove to New York and join the staff of the American Geographical Society as director of the society's work and librarian. The geographers of the country generally will doubtless be glad to hear that this society, whose activities are constantly widening, have been able to enlist the services of Professor Bowman in the promotion of its future work.

PROFESSOR CHARLES P. BRERKE, of the department of geology, Columbia University, has been appointed as an expert to select, classify and preserve borings taken from the sites of buildings in all parts of New York City, and to prepare geologic maps of the city. The appointment comes from the board of estimate.

THE secretary of the Smithsonian Institution, with the approval of the secretary of agriculture, has appointed Dr. Charles H. T. Townsend to the honorary position of custodian of *Muscoid diptera*, in the United States National Museum.

W. L. DISTANT has resigned the editorship of the *Zoologist*.

DR. VIKTOR BOHMERT, formerly professor of political economy and statistics at Dresden, has celebrated the sixtieth anniversary of his doctorate.

DR. JULIUS BERNSTEIN, formerly professor of physiology at Halle, has celebrated his seventy-fifth birthday.

THE council of the Geological Society, London, has this year made the following awards of medals and funds: Wollaston medal, Professor T. W. Edgeworth David, O.M.G., F.R.S.; Murchison medal, Professor W. W. Watts, F.R.S.; Lyell medal, Professor E. J. Garwood, F.R.S.; Bigsby medal, Mr. H. H. Hayden; Prestwich medal, Professor Emile Cartailhac (Toulouse); Wollaston Fund, Mr. O. B. Wedd; Murchison Fund, Mr. D. C. Evans; Lyell Fund, Mr. John Parkinson; and Dr. L. Moysey; Barlow Jameson Fund, Mr. J. G. Hamling.

THE council of the New York Academy of Medicine for 1915 is composed of the following members: Dr. Walter B. James, presi-

dent, Dr. L. Emmet Holt, Dr. S. S. Goldwater and Dr. Edward D. Fisher, vice-presidents, Dr. Charles F. Adams, recording secretary, Dr. D. Bryson Delavan, corresponding secretary, Dr. Reginald H. Sayre, treasurer, Dr. A. Alexander Smith, Dr. Charles L. Dana, Dr. John H. Huddleston, Dr. W. Gilman Thompson and Dr. Wisner R. Townend, trustees, Dr. Floyd M. Crandall, chairman of the Committee on Admissions, Dr. Thomas L. Stedman, chairman of the Committee on Library, Dr. Robert H. Halsey, assistant secretary, Dr. A. B. Judson, statistical secretary, Dr. Charles Mallory Williams, executive librarian.

A COMMITTEE on the Biological Station, of the University of Michigan, has been appointed consisting of Professor Gleason, director of the biological station, chairman, Professor Reighard, head of the department of zoology, Professor Newcomb, head of the department of botany, Professor Guthe and Professor Kraus, deans of the graduate school, and the summer school, to consider all questions of policy, budget, staff, equipment, instruction and other matters pertaining to the welfare of the station.

PROFESSOR HENRY E. CRAMPTON, of the department of zoology, Columbia University, is spending a month in Porto Rico in the interest of the natural history survey of that island which is being conducted by the New York Academy of Sciences.

THE Pennsylvania chapter of the Society of Sigma Xi met on January 13. Professor Lightner Witmer, director of the university psychological laboratory and clinic, presided. Supper was served in Houston Hall. Members of the psychological department later gave a demonstration of experimental work in psychology, and Professor Witmer presented a paper on "Psychology as a Department of Instruction."

DR. HENRY S. DRINKER, president of Lehigh University and the American Forestry Association, delivered an address at the University of Illinois on January 18, on "The Conservation of Our National Resources."

DR. FELICE FERREBO will lecture at New York University on February 19 on "Galileo and the Struggle between the Old Science and the New"

AN illustrated lecture was given on January 12, 1915, by Mr William Bowie, inspector of Geodetic Work, U S Coast and Geodetic Survey, Washington D C, before the Engineering Club of Northwestern University, Evanston Ill The subject of the lecture was "Primary Triangulation and Precise Levelling"

MR J C THORPE formerly professor in the engineering faculty of the University of Illinois gave recently there a series of four illustrated lectures on the automobile

DR JAGADIS CHUNDER BOSE, of Presidency College Calcutta, gave a popular lecture on "Plant Autographs and their Revelations" at the University of Wisconsin on Friday, January 22, 1915, under the joint auspices of the Society of the Sigma Xi and the Science Club of the University of Wisconsin A smoker at the University Club in honor of Dr Bose followed the lecture

THE monument on Mount Mitchell erected twenty six years ago in memory of Professor Elisha Mitchell for whom the mountain was named, has been destroyed by dynamite It is not known who committed the act Professor Mitchell, a member of the faculty of the University of North Carolina, established the height of the peak as 6,711 feet He eventually lost his life while exploring the mountain

A MEMORIAL meeting in honor of Albert Smith Bickmore was held in the American Museum of Natural History on January 29, when the program included addresses by President Henry Fairfield Osborn, Mr Joseph H Choate Mr Cleveland H Dodge, Dr John M Clarke and Mr L P Gratacap Professor Bickmore was in large measure responsible for the founding of the American Museum and was a leader in its educational work

At the recent annual public session of the Académie de médecine, Paris, the family of

Pasteur presented to the academy a portrait bust of Pasteur by Paul Dubois

DR. CYRUS FOGG BRACKETT, professor emeritus of physics in Princeton University, died on January 29, in his eighty second year

DR. BENJAMIN SHARP, formerly corresponding secretary of the Philadelphia Academy of Natural Sciences and professor of invertebrate zoology there and in the University of Pennsylvania died on January 24, at Morehead, N C, aged fifty six years

DR JULIUS WEEREN, formerly professor of metallurgy in the Berlin Technical School, has died at the age of eighty three years

THE death is also announced of Dr Rudolf Fischer, director of the Coburg Museum of Natural History and of Dr Lothar von Frankl Hochwart, professor of pathology of the nervous system at the University of Vienna

AMONG those reported killed in the war are Dr Max Brandt assistant in the Botanical Museum at Berlin Dahlem, Dr Wilhelm Schneider, assistant in the Agricultural Institute at Giessen, Dr Werner Hirschfeldt, assistant in the Industrial Museum at Stuttgart, and Dr Karl Pfarr, professor of mathematics and physics in the Vienna Industrial Academy

In answer to the manifesto of the German intellectuals, which is considered as unifying German culture and German militarism, La Société Nationale d'Acclimatization de France has decided to remove from its list of members all Germans and Austrians

THE board of trustees of the University of Illinois has given the sum of five hundred dollars to the fund inaugurated for the purpose of erecting a laboratory at Rothamsted in commemoration of the centenary of the birth of Lawes in 1814 and of Gilbert in 1817

THE will of Alexander A McKay, of Chicago, bequeaths \$100,000 to the Art Institute for the maintenance and enlargement of the Munger collection of paintings, \$100,000 to the Home for Destitute Crappled Children and \$100,000 to the Mary Thomson Hospital for women and children

At the exercises held in the Engineering Societies Building, New York, on January 27, in connection with the inauguration of the Engineering Foundation, it was announced that the initial gift had been made by Mr Ambrose Swasey, past president of the American Society of Mechanical Engineers who gave \$200,000 for "the advancement of the engineering arts and sciences in all their branches to the greatest good of the engineering profession and for the benefit of mankind" Addresses were made by Mr Gano Dunn, president of the United Engineering Society, by Dr Henry S Pritchett, president of the Carnegie Foundation for the Advancement of Teaching, by Dr Robert W Hunt, past president of the American Institute of Mining Engineers and by Dr Alexander C Humphreys past president of the American Society of Mechanical Engineers and president of the Stevens Institute of Technology The administration of the fund will be intrusted to the Engineering Foundation Board, elected by the trustees of the United Engineering Society and composed of eleven members, nine from the American Society of Civil Engineers, the American Institute of Mining Engineers, the American Society of Mechanical Engineers and the American Institute of Electrical Engineers, and two members chosen at large

A JOINT meeting of Section G (botany) of the American Association for the Advancement of Science with the Botanical Society of America and the American Phytopathological Society was held in Philadelphia at 2 P M, December 29, 1914 Vice president G P Clinton presided The following officers were elected For member of the sectional committee for five years, C S Gager, for one year, A D Selby, for member of the council, L R Jones, for member of the general committee, W L Bray The sectional committee recommended, and the association elected, W A Setchell as vice president The following papers were read

Address of the retiring vice president, "The Economic Trend in Botany," by H C Cowles

"Foliar Evidence in Regard to the Ancestry and Early Climatic Environment of the Angiosperms"

(illustrated by lantern slides), by E W Sinnott and I W Bailey

"Physiological Eccentricities of the Blueberry Plant" (illustrated by lantern slides) by F V Coville

"Plant Autographs" (illustrated by lantern slides and experiments), by J C Bose

THE twenty seventh annual meeting of the American Association of Economic Entomologists was held at the University of Pennsylvania, December 27 to 31 1914 The address of the president, Dr H T Fernald, was delivered at the first session and the program was crowded with over forty papers, all of which were of special interest to economic workers The section of Apiary Inspectors met at 8 P M on December 27 and the Section of Horticultural Inspection held its sessions at 8 P M on December 28 and 10 A M on December 29 Many papers of interest were presented at these sessions and discussions as to methods and the present status of inspection work followed A draft of a uniform state law covering nursery and orchard inspection was favorably considered The next annual meeting will be held at Columbus, Ohio, in connection with the annual meeting of the American Association for the Advancement of Science and the executive committee was directed to call a special meeting at San Francisco during the summer The officers for 1915 were elected as follows President Professor Glenn W Herick, Ithaca N Y First Vice president, Professor R A Cooley, Bozeman, Mont, Second Vice president Professor W E Rumsey, Morgantown, W Va, Third Vice president Dr E F Phillips Washington, D C, Secretary, A F Burgess Melrose Highlands, Mass Professor J G Sanders, Madison, Wis, is secretary of the Section of Horticultural Inspection and Mr N F Shaw, Columbus, Ohio, secretary of the Section on Apiary Inspection A full report of the meeting will be published in the *Journal of Economic Entomology*

A COLLECTION of Cretaceous fossils has been purchased by the department of geology and invertebrate paleontology of the American Museum of Natural History from Dr A Schrammen, of Hildesheim, Germany It con-

sists of eleven hundred species of invertebrates represented by four thousand specimens which were collected from some fifty localities and fourteen geological horizons in the upper and lower Cretaceous beds of northwest Germany. The phyla and sub phyla represented are the foraminifera, spongia, hydrozoa, anthozoa, echinoidea, annelida, brachiopoda, gastropoda, pelecypoda and cephalopoda. Among the pelecypoda and cephalopoda are to be found the type specimens of Wolleman in his work on the Cretaceous of Misburg and Nettingen. The most valuable portion of the collection is the large number of types of siliceous sponges from the Mucronaten and Quadraten Senonian strata.

THE free lecture course of the Ottawa Field Naturalists' Club opened on November 23, with exhibits and addresses by members, in the Normal School Assembly Hall. The remainder of the program is as follows:

December 8—"The New Zealand Peripatus—the most Ancient and Wonderful of Living Animals" by Professor E. E. Prince, Dominion Commissioner of Fisheries, Ottawa.

January 12—"The Royal Botanic Gardens, Kew," by Professor R. B. Thomson, Botanical Laboratory, University of Toronto.

January 26—"The Indians of the West Coast," by Dr. Edward Sapir, department of anthropology, Geological Survey, Ottawa.

February 9—"Fossils," by Mr. L. D. Burling, Geological Survey, Ottawa.

February 23—"Milk," by Mr. J. H. Griesdale, Director Experimental Farm, Ottawa.

March 9—"Some Interesting Canadian Birds," by Dr. M. Y. Williams, Geological Survey, Ottawa.

March 23—Annual meeting and presidential address "The Habits of Insects in Relation to their Control," by Mr. Arthur Gibson, entomological branch, Department of Agriculture, Ottawa.

The first four meetings are at the Normal School and the last four in cooperation with the Carnegie Library in its Assembly Hall.

MR. HENRY S. WELLCOME, founder of the Wellcome Bureau of Scientific Research, in London, has announced that the bureau will provide the sum of £2,000 to be distributed in the form of prizes for the best plans and designs of a body for and improvements in, field

motor-ambulances. The competing designs, which may be from citizens of any nation, must be received by the commission not later than June 30. Details may be obtained from the secretary of the Ambulance Construction Commission, 10 Henrietta Street, Cavendish Square, London, W.

THE *Journal* of the American Medical Association states that the New York state hospital commission which is charged with the supervision and control of the state hospitals for the insane is planning a campaign of prevention. During the past year 6,061 patients were received at the state hospitals of whom about one quarter owed their breakdown to causes largely under their control. The plans of the commission comprise a series of short illustrated talks on mental hygiene to be delivered in different parts of the state, showing to the public the economic burden imposed on the state through insanity, the causes and prevention of insanity and the problems of faulty heredity and environment. The plan also includes the giving of assistance to individuals in the form of advice as to how to obtain proper medical treatment and advice as to the maintenance of mental hygiene. The teaching and pathological branch of the service will be under the direction of Dr. August Hoch, New York City. The lectures will be given under the direction of the commission, with the approval of Health Commissioner Biggs.

THE spreading of rabies by infected coyotes among cattle grazing in the national forests has assumed a grave aspect, according to a report received by the forest service from the district forester in charge of the forests in Washington and Oregon. Numerous townships in eastern Oregon, it is reported, have ordered that all dogs be muzzled, lest those that have been bitten by rabid coyotes develop hydrophobia and attack human beings or domestic animals. Efforts are being made by the state authorities of Oregon to stop the spread of hydrophobia by this means and officers of the forest service are cooperating in attempts to kill off the coyotes. In one county alone a loss of three hundred head of cattle is charged to rabid coyotes.

UNIVERSITY AND EDUCATIONAL NEWS

THE sum of \$40,000 has been given by Mr Andrew Carnegie to Allegheny College for a chemical laboratory to replace the one recently destroyed by fire

MR PATTEN, who has already given \$500, 000 to the medical school of Northwestern University, has now added \$27,000 for scholar ships

PROFESSOR O H PLABODY, head of the department of naval architecture at the Massachusetts Institute of Technology, has been notified by the Aero Club of America of the establishment of an award in the form of a medal for the students at the institute. The medal is to be termed the "Aeronautical Engineers' Medal" and is for award annually for merit to a student in the graduate course in aeronautical engineering

AT the University of Chicago Dr Frank Christian Becht has been appointed assistant professor in the department of physiology, his particular field of work being pharmacology. Professor Becht, who is a graduate of the University of Chicago, was for two years assistant professor of physiology in the University of Illinois and later assistant professor of pharmacology in the Northwestern University Medical School

IN the medical department of the University of Oregon Dr J M Connolly has resigned as professor of physiological chemistry and Dr H D Haskins, of Western Reserve University, Cleveland, has been elected his successor. Dr B L Arms has resigned as professor of bacteriology to accept a position in the University of Texas and Dr W H Norton, of Johns Hopkins Medical School, has been appointed to the vacant position

TWO professors from Louvain University—MM Charles Jean de Valée Poussin and Léon Dupriez—have been invited by Harvard University to deliver lectures in the second semester. The former will lecture on mathematics, the latter will give the Godkin lectures on "Proportional Representation in Belgium" and two courses

DISCUSSION AND CORRESPONDENCE

THE FUNDAMENTAL EQUATION OF MECHANICS

IN his recent review of Maurer's "Technical Mechanics,"¹ Professor L M Hoskins has discussed at some length the question whether $F=ma$ or $F/F'=a/a'$ is the better form in which to introduce the "fundamental equation of mechanics." As Professor Hoskins' defense of the equation $F=ma$ is the clearest I have seen, and as I am still one of those who prefer the equation $F/F'=a/a'$, I should like to state here the advantages which this latter equation seems to me to possess

In the first place, the qualitative notion of *force* and the use of the *spring balance* as an instrument for the quantitative measurement of forces, may safely be assumed to be familiar to any one beginning the study of mechanics.²

The first serious problem, then, which confronts the teacher of dynamics is the problem of making the student understand the effect which a force produces when it acts on a material particle. This effect is, of course, the acceleration of the particle in the direction of the force, the exact quantitative relation being most simply stated as follows

If a given particle is acted on at two different times by two forces F and F' , and if a

¹ SCIENCE, December 4, 1914

² The question of the unit of force, which occupies so large a place at the very beginning of the subject in the ordinary treatment need not be dwelt upon at this stage. To the beginner a unit force is quite properly any force which brings the pointer of a standard spring balance to the point marked "1" on the scale, whether the instrument reads pounds, or dynes, or grams, just as a degree of temperature is to the beginner, simply the distance between two divisions of the scale of a standard thermometer, whether that scale reads Fahrenheit Réaumur or Centigrade. The conversion factors connecting the various degrees of temperature should indeed be stated, but the question of ultimate standards, being chiefly a question for the technician, need not be raised at this point. For further details, see the writer's "Recommendations Concerning the Units of Force," in the *Bulletin of the Society for the Promotion of Engineering Education*, June, 1913, the most important of which have already been adopted by the U S Bureau of Standards

and a' are the corresponding accelerations, then $F/F' = a/a'$, that is, the accelerations are proportional to the forces

When once this simple principle is thoroughly grasped, the student finds himself immediately in a position to attack any of the elementary problems in the dynamics of a particle (in one dimension). For, by this principle, the effect of any force on a given particle can at once be computed if the effect of any one force on that particle is known. In other words *the dynamical properties of any given particle of matter are completely determined by a single physical experiment on that particle* and the result of such an experiment must be known or assumed with regard to every particle which enters into the discussion of a dynamical problem.³ It is the chief advantage of the equation $F/F' = a/a'$ that by its use the student is led by the shortest possible route, into direct and vital contact with this central fact of dynamics—namely, that different bodies require different amounts of force to give them any specified acceleration. The whole further development of the science is essentially a matter of working out details and introducing convenient terminology for such derived quantities as mass, momentum, kinetic energy, work, power, etc.

What then is the objection to the use of this equation?

Professor Hoskins expresses his objection as follows

An equation which results from comparing the effects of different forces upon the same body can not, of course, be regarded as a complete expression of the fundamental law of motion, it is equally important to compare the effects of forces acting upon any different bodies. This of necessity brings in the body constant which most physicists call mass

In reply to this objection I would say, in the first place, that the question whether a given equation can be regarded as a "com-

³ The "standard weight" of a particle is the force required to give the particle the "standard acceleration," 32.1740 feet per second per second, the standard weight of a composite body is defined as the sum of the standard weights of the particles of which it is composed

plete expression of the fundamental law of motion" depends simply on whether all the theorems of dynamics can be deduced from this equation, and not on how the equation itself happens to have been derived. In the second place, I quite agree that in order to handle dynamical problems successfully we must indeed be able to discuss the "effect of different forces on different bodies", that is, we must be able to determine the inertia, or mass, of each particle under consideration. But so also must we be able to discuss the momentum and kinetic energy of the different bodies, but that is no reason why a letter denoting mass, or momentum, or kinetic energy, should appear explicitly in the fundamental equation. From the point of view of scientific economy, the fewer letters that equation contains, the better. The mass concept like the concept of momentum or kinetic energy, is a derived concept, both historically and practically and it seems to me a merit of the plan here advocated that on this plan the derivative character of all these quantities is explicitly apparent in the mathematical development of the equations.

So much for what may be called the force method of beginning mechanics

A second method of developing the whole subject might be to adopt *mass* instead of *force* as the fundamental concept—as has been done, for example by Mach and by Boltzmann. This method seems to me, however open to three serious objections

First, the instrument commonly taken as the fundamental means of measuring mass—namely the beam balance—is essentially a *gravitational* instrument, depending for its operation on the (established or assumed) equality of the gravitational fields of force at the two ends of the beam, whereas the instrument for measuring forces, at least in a readily idealized form, is a *universal* instrument, not in any way dependent on locality. For example, if a man should be placed, in imagination, at the "point of zero gravity" between the earth and the moon, it is not at all obvious how he would proceed to measure a given mass with a beam balance, whereas, if he had a spring

balance, in the form, for example, of a grip-testing machine, he could measure the strength of the muscles of his hand, or the attraction between two bodies, just as well under those circumstances as if he were on the surface of the earth.

Secondly if we are dealing with only a portion of the physical universe (as is always the case in practical problems), we must either introduce "forces" to account for the action of the residual portion, or else resort to very artificial conventions in regard to "imaginary masses" (It should be noted that the "mass acceleration" of a body can not conveniently be taken as a substitute for an external force acting upon that body, for the mass acceleration of the body, like its momentum or kinetic energy, is a quantity inherent in the body.)

Thirdly, the approach to statics, in which the concept of mass plays no part whatever, is peculiarly awkward by this route, whereas if force is taken as the fundamental concept, the problems of statics may readily be taken up either before or after the detailed study of dynamics.

While therefore it is logically possible to choose either mass alone or force alone as the fundamental concept, the latter choice seems practically preferable.

Either the force method or the mass method I say, is logically defensible, but the method which starts with the equation $F=ma$ is neither the force method nor the mass method. My chief objection to this hybrid equation $F=ma$ is precisely this uncertain wavering between the force concept and the mass concept as the fundamental notion of the science. This wavering is I believe, the main source of the very real difficulties which the student experiences in regard to "units"—difficulties which are not necessarily functions of the laziness or immaturity of the student, but which are felt more keenly by those of a scientific and critical turn of mind than by those of a merely practical bent. I quite agree with Professor Hoskins that any student of dynamics ought to have sufficient intelligence to grasp the idea of a *systematic system of units*, that is, a system in which certain units

are taken as fundamental, and all others are derived, but I do think that the student has a right to expect that the quantities which appear in the so-called fundamental equation shall be the same as the quantities which are taken as fundamental in the system of units. *This is not the case with the equation $F=ma$.* The trouble with this equation is not that it contains mass, but that it contains *both force and mass*, while not both of these quantities are regarded as fundamental in the subsequent treatment.

The use of the equation $F/F' = a/a'$ seems to me, therefore not merely a matter of practical convenience but also a distinct advance in scientific precision of thought.

EDWARD V. HUNTINGTON

HARVARD UNIVERSITY

GEOLOGIC HISTORY OF LAKE LAHONTAN¹

IN reference to the summary concerning the probable history of Lake Lahontan by J. O. Jones, contained in *SCIENCE*, December 4, 1914, while I am much interested in Professor Jones's conclusions concerning the origin of the tufa, I feel that his statements regarding the interpretation of the age of Lake Lahontan need some important qualifications, and that his conclusions as to the probable accumulation of salines in Lahontan waters are not at all the necessary deductions from the evidence that he has cited.

Professor Jones's estimates on the age of Lake Lahontan and the quantity of salines that might have been deposited by the evaporation of its waters fail to take into account some very important considerations. The assumption that because Pyramid Lake may be and probably is a remnant of Lake Lahontan, which has never been dried up completely, therefore its salines are an index of the age of the whole larger lake seems to me erroneous. A conception of a closer interpretation may perhaps be obtained in the following way.

No one doubts that Lake Lahontan formerly rose to a height of approximately 500 feet above present Pyramid Lake and that its

¹ Published by permission of the Director of the United States Geological Survey.

waters have since largely disappeared through diminishing water supply. The water supply that maintained the larger lake, as that which maintains the smaller lakes of the present day came principally from a few major streams draining from the higher Sierra. Of these Truckee, Carson and Walker rivers were with little doubt the dominating factors. The following is an outline map showing the general relation of these drainage systems

Outline Map Showing Truckee Pyramid Drainage System and its Former Northward Extension

Approximate equilibrium was maintained in the larger Lake Lahontan through the balance of evaporation and inflow. Evaporation varies directly with the surface area of the water body. Inflow is supposed to have been gradually decreasing as the lake level was falling. When however the waters fell to the level of

any divide which would separate the basin into two or more distinct parts, the equilibrium that had been maintained for the lake body as a whole would hardly be continued in exactly proportionate relations in the two separated parts. Each part must have then established a new relation of separate inflow and evaporation ratio and it is almost a certainty that an overflow would for a time be established from one side toward the other over the intermediate divide.

Such an overflow may have occurred over the Fernley divide from the Truckee Basin into the Carson Basin. The evidence of channels there is not very clear. At lower elevation however such an overflow did occur from the Pyramid Basin into the Smoke Creek and possibly beyond. The channel of this overflow is indisputably clear, broad and well defined. Its bottom is only 70 feet above the present water level of Pyramid Lake. The surface of the Smoke Creek desert to the north is below the water level of Pyramid Lake to day. The Smoke Creek and the more northern deserts have no present perennial water supply. Although subject to floods from winter storms, they are essentially dry basins. The waters that filled these basins during the higher Lahontan stages came with little doubt principally from the Truckee River. The chief water supply of these broad evaporation areas came therefore through the more restricted basin of Pyramid Lake and flowed by way of a narrow pass at the north end of Pyramid Lake. As a late stage in the lake history the waters of Lahontan lowered beyond the 70 foot level above present Pyramid Lake level and a distinct overflow drainage was set up out of Pyramid toward the north. During all this time that concentration of Lahontan waters was going on the lake in Pyramid Basin was being freshened by overflow. Only when the flow of Truckee River had diminished to such an extent that it no longer exceeded evaporation within the restricted basin of Pyramid (including Winnemucca as in all previous references) did concentration within the Pyramid Lake waters proper, begin. Estimates of age based on this concentration may indi-

into therefore something as to the age of this latest and perhaps shortest stage of Lahontan history, but they can hardly represent any stage more. Tufa deposits above the Pyramid quiet level have no simple relation to the quantity of salines now retained in Pyramid waters, nor can any simple deduction be reasoned therefrom. If Pyramid Lake waters are comparatively fresh that is more likely to be the result of freshening by overflow than of freshening by desiccation. However desiccation of Lahontan waters and perhaps of concentrated saline solutions may have taken place in the dry basins to the north. Large quantities of salines were accumulated in an analogous system below the Owens River and owing to natural relations there they have not since been covered up. There is a good chance that similar deposits may have been formed in some concentration sink of the Lahontan Basin which have since been buried in playa sands.

HOYT S. GALE

WASHINGTON, D. C.

BOTANY IN THE AGRICULTURAL COLLEGES

DR. E. B. COPELAND'S article in *SCIENCE* for September 18, 1914, entitled "Botany in the Agricultural College," opens up for discussion a many-sided problem of high pedagogical importance to agriculture. While we may agree to the definition that the raising of crops is essentially nothing more or less than applied botany, it is a pitiful commentary that what we know of the raising of crops has in the main been gained without the help of the botanist. Indeed one of our best known American botanists contends that problems of crop production may safely be left wholly to the agronomist and horticulturist.

The chemist infinitely more than the botanist has interested himself in the great problem of securing a larger crop return from the soil. Indeed one must give high credit to the chemists for the insistent efforts they have made to bring their science into affiliation with all other sciences and with practical industries. We have to day almost endless subdivisions of chemistry, such as biological chem-

istry, agricultural chemistry, engineering chemistry, physiological chemistry, bacteriological chemistry, etc. There is hardly a line of human endeavor to which the chemist has not striven to apply his knowledge in a practical way. Much of the so-called agricultural chemistry is more properly plant physiology, but chemists have occupied the field with scarcely a protest from botanists. In striking contrast to the chemist, botanists have shrunk from what should be the major application of their science, namely that of crop production. A marked exception is plant pathology, along which line the best contributions of botanists to agriculture have been made. In very recent years the study of genetics as applied to agricultural crops also promises to produce much of high economic value. It is true that there are numerous texts purporting to treat of agricultural botany, but they are mostly of a character creditable to neither agriculture nor botany. The best texts that relate to agricultural botany or at least to crop production have been written not by botanists but by chemists.

Perhaps no one really questions that the study of the factors that go to make crop production is the province of plant ecology and of plant physiology, including genetics, but one may search the whole literature of these subjects without finding a single paper devoted to the relation of any one environmental factor to quantity and quality of yield, the very thing with which crop production is concerned. Botanists seem scarcely to have realized that yield is a measurable result of the same sort as the rate of growth or the amount of water transpired or of carbon assimilated.

Our actual knowledge of the relation of factors both external and internal to yield is very largely the work of non-botanists. Indeed excepting for the work of chemists it is still largely confined to the facts gathered by actual experience in the growing of crops, most of it antedating the development of modern science.

Since the advent of modern science six great discoveries or lines of advance have contributed to greater crop production or at least to a

clearer understanding of the factors involved. These are as follows:

The Gaseous Food of Plants—Knowledge of these centers about the discovery of carbon dioxide assimilation (photosynthesis) and oxygen respiration the main points of which were cleared up by Ingen House (1779-1796) and Senebier (1782-1800). Saussure (1804) first proved that plants combine water with carbon dioxide in carbon assimilation.

The Mineral Food of Plants—Saussure (1804) recognized clearly the necessity of the ash constituents of plants and that these were derived from the soil. The conception however was much older dating back at least to Palsy in 1563. These ideas however met with little acceptance until after 1840 when the writings of Liebig and the experiments of Boussingault, Salm-Horstmar and others cleared up all the important points before 1860. Liebig must be considered as the great dynamic force that impressed the importance of this knowledge on agriculture. While some of Liebig's ideas were erroneous his writings profoundly affected agriculture and his general ideas of the importance of mineral fertilizers dominated scientific agriculture until the beginning of the present century and still exercise a potent influence. The fertilizer experiments conducted by Lawes and Gilbert at Rothamsted still remain the most extensive of their kind and their results have contributed much to support Liebig's theory.

The Organic Food of Plants (Nitrogen)—Liebig believed that all ordinary plants obtained their nitrogen directly from the ammonia in the air but Boussingault (1851-5) proved that various plants would not thrive in a soil containing all essential elements but nitrogen but grew normally if nitrates were added.

While the fact had been known long previously that ammonia became changed into nitrates in soil Schloesing and Muntz (1877) first proved that it was due to microorganisms which were finally isolated by Winogradsky in 1890.

Hellriegel (1888) demonstrated that legumes are able to utilize atmospheric nitrogen through the agency of bacteria in the root nodules. It

was previously known that these plants could obtain more nitrogen than was present in the soil.

Plant Breeding—Three other discoveries have led to great improvement in our crop plants themselves. These are (1) The proof of the sexuality of plants by Camerarius 1691-4 (2) the hybridization of plants by Kolreuter 1760-1770 (3) the discovery of the laws of hybridization Mendel 1865.

Improvement in Mechanical Appliances—The development of improved machinery for the tillage of the soil, the sowing of the seed and the harvesting of the crop has had a profound influence both in increasing the amount and decreasing the cost of production. The invention and improvement of agricultural machinery has been the work of a long list of inventors.

Control of Insects and Diseases—The important methods for the direct control of insects and plant diseases center about the discovery of Bordeaux mixture by Millardet in 1885 of the use of Paris green for biting insects beginning about 1868, the value of kerosene emulsion for sucking insects about 1877, and the development of fumigation with hydrocyanic acid gas 1886-1888.

Indirect methods of control have been greatly advanced by the investigations of both entomologists and plant pathologists.

Of these six lines of advance three are due almost wholly to chemists, one to mechanics, one wholly to botanists and one partly to botanists and partly to entomologists. It may be argued that the chemists' contributions are really plant physiology but this does not alter the fact that the work was done by chemists and that further research into the food of plants at least of crop plants is still largely directed by chemists and not by plant physiologists.

At the 1914 session of the Graduate School of Agriculture held at the University of Missouri, an incidental discussion led to a general expression of opinion regarding the training of American agronomists. There was complete agreement that the botanical side of their training is wholly inadequate. Indeed with

the exception of plant pathology it is exceedingly difficult to find graduates in botany whose training has given them either a taste or a qualification for the innumerable problems surrounding crop production. Almost none take the U. S. Civil Service examinations, the result being that the positions are mostly filled by graduates in agronomy with but meager botanical training.

The result of this condition of affairs is detrimental to the advance both of botany and of agronomy. The young botanist is neither trained nor encouraged to look upon the problems of crop production as the legitimate and greatest field for his future activities. Conversely, agronomy suffers because far too few botanists lend their aid to the study of plants under cultivation.

The charge has sometimes been made that botanists purposely avoid grappling with the enormously difficult physiological and ecological problems that every agronomist and horticulturist encounters. I do not believe that American botanists have ever consciously taken this attitude, but they have been willing to leave the work largely to chemists and others of very limited botanical training. In short, they have not asserted their rights to this field of plant phenomena nor proven them by actual accomplishment.

Botany has progressed greatly in America in the past twenty years, in spite of the fact that it has woefully neglected its greatest application; namely, crop production.

It is difficult to disagree with Dr. Copeland's proposition "that the best scientific foundation for plant industry is a knowledge of plant physiology," except to add that equally necessary is a knowledge of the adaptations of each plant, which is ecology. The fact remains, however, that plant industry or crop production far antedates botanical science, and most of its progress has been purely empirical; that even yet our knowledge of the physiology and ecology of any one crop plant is woefully incomplete.

I would go still further than Dr. Copeland, however, and assert that the whole field of plant culture or crop production is one of plant

ecology and plant physiology. Until this is recognized by botanists progress in crop production will continue to be largely the work of non-botanists.

C. V. PIPER
U. S. DEPARTMENT OF AGRICULTURE

IN REGARD TO THE POISONING OF TREES BY POTASSIO CYANIDE

IN SCIENCE of October 9, 1914, was published a short letter telling of a successful attempt at poisoning the cottony cushion scale by inserting cyanide of potassium in a hole bored in the trunk of the tree. I have since received a number of letters asking for further information regarding my "process," and telling me of numerous cases where trees have been killed by poisoning the sap with something beside potassic cyanide. I would accordingly like to take this opportunity of stating that I am not experimenting in either entomology or horticulture; that I have no process, and that I gave in my letter to SCIENCE a plain statement of the method and results of my experiment. I did this in the hope that it might serve as a suggestion to others who are working in the same field.

I was told by several of my colleagues who are working in biological subjects that any poison fatal to insects would kill a tree before I put the cyanide in the trees, and I have read in a recent number of SCIENCE of the destructive effects of putting potassic cyanide and something else under the bark of fruit trees. I have accordingly chopped down the peach tree referred to in my former letter and have examined both the wood and the bark around the hole in which the cyanide was inserted. In both the wood and the bark there was a discoloration around the hole extending less than one eighth of an inch. Outside of this ring I could notice no change in either. I am not positive that as great an effect would not have been produced if the hole had been left empty. One proof that the bark was not seriously poisoned about the hole was seen in the fact that it had begun to grow over the opening. This is also true in the case of the broom and the orange tree referred to in the previous letter. The peach tree was cut down

ten months after the cyanide had been put into it
FERNANDO SANFORD

QUOTATIONS

THE ORGANIZATION OF SCIENCE

Just before the beginning of the war much fruitful discussion was going on in the columns of *Nature* the *Morning Post* and *Science Progress* on the subject of the encouragement of science, and those who are interested in the theme should read Dr R S Woodward's address on the needs of research, delivered on the occasion of the dedication of the Marine Biological Laboratory, Woods Hole Massachusetts (SCIENCE, August 14, 1914)

Dr Woodward begins by exposing some of the popular fallacies regarding research—that it 'is akin to necromancy', and that "the more remarkable results of research are produced not by the better balanced minds, but by aberrant types of mind popularly designated by that word of ghostly, if not ghastly, implications, namely 'genius'." He has also exposed the absurdity that research institutions should busy themselves in soliciting suggestions from the amateur public outside, that is "in casting drag nets in the wide world of thought, or in dredging, as biologists would say, with the expectation that out of the vast slimy miscellanies thus collected there will be found by the aid of a corps of patient examiners some precious sediments of truth." He thinks that "important advances in knowledge are far more likely to issue from the expert than from the inexpert in research."

Dr Woodward traverses the idea 'that research is a harmless and a fruitless diversion in the business of education', and gives some figures as to the comparative expenditure of the United States on education and research respectively

The number of higher, or degree giving, establishments in the United States is now upwards of six hundred, the aggregate annual income of these is upwards of one hundred millions of dollars, and the number of officials connected with them is upwards of thirty thousand. On the other hand, the number of independent research organizations in

the United States is less than half a dozen; their aggregate annual income is less than two million dollars, and the number of officials primarily connected with them is less than five hundred.

Something very like this holds also in Britain, and indeed throughout the world. Men can not be made to understand, even with the astonishing results which investigation has placed before us, the supreme importance of such effort. They still conceive that it is more important to teach boys how to do things than actually to get the things done.

The war now raging will at least demonstrate one thing to humanity—that in war, at least the scientific attitude the careful investigation of details the preliminary preparation and the well thought out procedure bring success, where the absence of these leads only to disaster. So also in everything. After all, the necessity for research is the most evident of all propositions. But the question (which I hope will receive still more careful attention when the war is over) is: What can the state do to make the machinery of investigation the most efficient possible? The mere citing of popular misconceptions is not enough, we need to have specific programs. The October number of *Science Progress* contains one such program, which I hope will receive the attention of men of science. Whether all the items are accepted or not remains to be seen, but until the discussion is earnestly undertaken, we can scarcely hope that the state will give more help than it has done hitherto. Dr Woodward puts his finger upon a weak point in men of science as a body. "We are," he says, "as a class of too recent monastic descent to fit comfortably in our present social environment." That is just it. We are not strong enough in making our demands heard, and, in my opinion, this is not a virtue, but a neglect of duty.—Sir Ronald Ross in *Nature*

SCIENTIFIC BOOKS

Fauna Iberica Mamíferos By ANSEL CARRERA. Published by the Museo Nacional de Ciencias Naturales, Madrid, September 26, 1914. 8vo Pp xviii + 446, 143 figures in the text and 22 colored plates.

This work is the first thoroughly accurate and complete catalogue of the mammals of the Iberian peninsula and the Balearic Islands which has been published. It properly includes the marine mammalia of the surrounding seas which as the author justly remarks "are as much entitled to be regarded as forming a part of the mammalian fauna of the region as the marine birds and birds of passage are entitled to be reckoned as belonging to its avifauna."

The author also includes under the Primates an account of the ape of Gibraltar *Macaca sylvanus* (Jenne) stating with excellent logic that whether these animals were originally introduced from Africa as contended by some or whether existing as survivors of their race which once was widely spread over Europe as is testified by paleontological evidence they have been from time immemorial domiciled upon the Rock of Gibraltar and are therefore truly a part of the peninsular fauna.

The appearance of Mr. Gerrit S. Miller's Catalogue of the Mammals of Western Europe recently published by the trustees of the British Museum occurred when the work we are reviewing was about half written but as Miller's book is in English and only gives the terrestrial species found in Spain in many cases simply citing them as occurring on the peninsula the writer has not felt himself deterred by the more extensive Catalogue of his learned American friend from issuing the present work.

Investigation of the pages of this book shows that there are one hundred and twenty-two species or subspecies of mammalia which occur in the feral state on the peninsula. They are distributed as follows:

Orders	Genera	Species and Subspecies
Insectivora	7	17
Chiroptera	9	21
Carnivora	14	24
Primates	1	1
Rodentia	11	35
Artiodactyla	6	12
Cetacea	11	12
Total	59	122

From the foregoing it is plain that the peninsula possesses a relatively extensive mammalian fauna. The area of Spain, Portugal and the Balearic Islands somewhat exceeds the area of New England, the Middle States, Maryland and Virginia combined. The number of species of mammals occurring in the Iberian region indicates almost as rich a fauna as that occurring in the northeastern portion of the United States. One reason for the relative richness of the mammalian fauna of the peninsula is found in the extremely diversified character of its surface in which there is the greatest variety of climates ranging from that of the alpine summits of the Pyrenees and Sierras to the hot subtropical valleys of the south and east. Another factor is the probable survival in portions of this region of species elsewhere extinct in Europe and allied to those of north Africa. The genera *Macaca*, *Genetta* and *Mungos* may it is true be due to immigration from north Africa but are regarded by Trouessart and others as probably representing survivals from a Tertiary fauna which elsewhere in Europe has become extinct.

A very interesting feature of the Iberian fauna is the fact that through long isolation many forms have become subspecifically differentiated. The ibex and the chamois of Spain are distinctly different from those of Switzerland and the Alps of Italy and analogous differences in pelage and even in form are revealed in other genera. This fact is interestingly set forth in the pages of the work before us.

For Spanish readers and for those in other lands who desire to acquaint themselves with the mammalian fauna of Spain and Portugal this book is especially to be commended. Written in a singularly lucid and agreeable style embodying the results of the very latest studies and beautifully illustrated by the author himself who is not only a learned zoologist but a most skilful artist and draughtsman the work leaves a most charming impression upon the mind of the student. It is in its way a model and signalizes the great ad-

vance along the lines of scientific investigation which is being made in Spain under the wise and intelligent guidance of its enlightened sovereign. There was a time, not so long ago, when we did not look to Spain for advanced information along purely scientific lines; but that day has passed, and there has arisen in her institutions of learning a generation of young men trained in the most modern methods of observation and research, who are destined to give this noble people as high a standing in the realms of science as has been achieved by the students of other lands. Among the young men who are working successfully in this direction none stands higher than the indefatigable and talented author of the work before us.

W. J. HOLLAND

CARNEGIE MUSEUM,
December 28, 1914

The Modern High School: Its Administration and Extension. Edited by CHARLES HUGHES JOHNSTON, Ph.D. (Harvard), Professor of Secondary Education in the University of Illinois. New York: Charles Scribner's Sons, 1914. Pp. xviii + 847.

The present work is a companion volume to "High School Education" which appeared two years ago under the editorship of Professor Johnston. The earlier book deals with the evaluation and organization of high-school studies; the present with the social administration of the high school. A third volume is announced which will treat the problem of supervision, especially that of class teaching.

In the volume under review, the editor has sought to make the cooperative plan of treatment yield a well-organized body of material bearing upon the chief problems of high-school administration. He frankly takes the position that the primary purpose of the high school is utilitarian and social: in a democracy like ours, high-school education is a necessity and not a luxury. Even the secondary functions, such as the cultural, esthetic, moral and religious, must be worked over in the light of modern social needs and social ideals. The conscious purpose of the editor, therefore, has

been threefold: first, to establish more firmly the idea that the aim of the high school is social; second, to determine the relation of the high school to the other educational agencies of a democracy; and, third, to show, largely through the interpretation of concrete examples, how the work of students might be so administered that it would have the maximum socializing effect upon them. The thirty chapters are written by twenty-eight different authors, representing the various groups of specialists interested in high-school problems.

Part I. deals with "The Institutional Relationships of the High School." A chapter here is devoted to each of the following topics: the high school as a social enterprise; the legal status of the high school; business efficiency in high-school administration; the relation of the high school to the elementary school, to the college, and to the industrial life of the community. The contributors of these chapters are Dr. Snedden and Mr. Kingsley of the Massachusetts State Board of Education; Mr. Hanger, superintendent of schools, Rossville, Kansas; Mr. Josselyn, associate professor of school administration, University of Kansas; and Dr. Carlton, professor of economics and history, Albion College. In the discussion of the second and third topics, the need of expert service in both state and local school administration is forcibly brought out. Mr. Josselyn's treatment of the articulation of the high school to the elementary school is based upon the idea that waste must be eliminated in the lower grades and that the upper grade work must be differentiated so as to integrate with the different lines of work now being offered in the high school. His charts upon the latter point are suggestive. Mr. Kingsley's discussion of the relation between high school and college contains one interesting suggestion; namely, that the high school ought to help the students select their colleges or universities and then guide their election of studies to this end. Perhaps the most difficult relationship of all, that of the high school to the industrial life of the community, receives but twenty of the two hundred and eight pages in this part. However,

the long chapter on continuation work later in the book supplements this and might have been included here

Part II entitled *The More Intimate Specialized Relationships of High School Work* has to do with the socialization of the curriculum class room management and study and with the bringing of the home and community into more vital relationship. The authors of these chapters are Dr Scott and Miss Williams of the Boston Normal School Mr Hall Quest assistant in education University of Illinois Mr Wiener principal of Central Commercial and Manual Training High School Newark New Jersey Mary V Grice founder of Home and School League Philadelphia and Mr Olinger principal Westminster Hall Lawrence Kansas. These chapters are rich in illustrative material. The chapter by Miss Williams describing the way she transformed her class in physiology into an active social group for the investigation of vital questions in community hygiene should be read by every high school teacher. In Mr Hall Quest's article on the direction of study all the chief schemes of supervised study are reviewed. The chapter by Mary V Grice on the Home and School Association is exceptionally strong because of its pointed and practical suggestions.

Part III takes up the "Definite Internal Expressions of the Social Nature and Socializing Function of the High School." The topics treated are the internal government of the school the improvement of teachers in service the guidance of the social activities of the high school athletics debating school paper and fraternities. The social point of view is consistently followed in all the discussions. A large number of different means of dealing with these activities now in operation are described. The chapter on "High School Journalism" is well worth careful reading by any one on the advisory board of a school paper.

Part IV brings together a group of "Additional Socializing Functions of the Modern High School." The following are the topics

with authors: *The High School as a Social Center* by Dr Perry of the Russell Sage Foundation *Continuation Work* by Dr Davis University of Michigan *High School Library* by Florence Hopkins librarian Central High School Detroit *Vocational Guidance* by Meyer Bloomfield director of Boston Vocation Bureau *Avocational Guidance* by Dr Ruediger of George Washington University *Cooperation in the Teaching of English* by Professor Hasic of Chicago *Normal High School Hygiene* by Dr Rapeer New York Training School *The School as an Art Center of the Community* by Ella Bond Johnston chairman art department, General Federation of Women's Clubs *The Moral Agencies affecting High School Students* by Mr Hanna state supervisor of High Schools Illinois and *The Religious Life of the High School Student* by Professor Wilm of Wells College. For the average teacher and principal certain of these chapters are especially helpful since they contain vital material on topics comparatively new. Notable in this respect are the treatments of the high school library the high school as an art center avocational guidance and cooperation in the teaching of English.

In spite of the clear purpose in the editor's mind the cooperative method of treatment has failed in one respect. Most of the contributors lay the theoretical groundwork for their discussion and while the material is good the reader still finds himself becoming very tired of repetitions. If close readers alone were to use the book one hundred and fifty pages or more might be eliminated without doing great violence to the work. The part headings too are somewhat artificial and strained and go little way toward helping establish standard captions under which to discuss school administration. Aside from these weaknesses the book contains the best body of assembled material on high school administration. Excepting a small number of the more general chapters and a considerable number of introductory paragraphs in others the editor has realized his purpose—a survey of policies, examples and suggestions of ways and means of making

the strictly socializing work of our actual high schools more definite more effective and more nearly universal. The sixty seven pages of bibliography at the close of the book deserve the highest praise. The titles are carefully selected well arranged and in part annotated. The editor has rendered a great service to students of secondary education especially those offering courses in the subject.

CLAYTON C KOHL

PLANT AUTOGRAPHS¹

THE importance of investigations on physiology of plants lies in the fact that it is only by the study of the simpler phenomena of irritability in the vegetal organisms that it is possible to elucidate the more complex physiological reactions in the animal. The difficulty of investigation lies in the apparent immobility of the plant. It is often impossible by visual inspection to distinguish even between specimens one of which is alive and the other killed. Means have therefore to be discovered by which the plant itself is made to reveal its internal condition and changes of that condition by characteristic signals recorded by it. These responsive reactions may manifest themselves in change of form or in change of electric conditions. In his investigations the author has employed both methods of mechanical and electric response.

In recording mechanical response great error is introduced from friction of the writer against the recording surface. This has been overcome in the author's Resonant Recorder where the record consists of a series of intermittent dots due to the vibration of the writing point. In this manner it is possible to record time intervals as short as a thousandth part of a second. Moreover in order to eliminate completely all personal equation the apparatus has been made perfectly automatic. Thus the plant attached to the recording apparatus is automatically excited by a stimulus absolutely constant. In answer to this it

makes its own responsive record, goes through its period of recovery and embarks on the same cycle over again without assistance at any point from the observer.

Mimosa exhibits a remarkable periodic variation of excitability the response being practically abolished in the early hours of the morning the sensibility is gradually increased to a maximum by noon. The latent period of the leaf is one six hundredth part of a second. Crucial tests of the excitatory character of transmitted impulse are afforded by physiological blocks produced by the local application of cold of poison and electrotonic block. These prove that the transmission of excitation in *Mimosa* is a process fundamentally similar to that occurring in the animal. The effects of drugs on plants are remarkably similar to the effects on animal tissues. The characteristics of the rhythmic tissues in animals and plants are precisely similar. There is hardly a single phenomenon of irritability observed in the animal which is not also to be found in the plant.

SPECIAL ARTICLES

INHERITANCE IN THE HONEY BEE

MORE or less time has been devoted by the writer during the past four years to a study of inheritance in the honey bee as a project under the Adams Fund. Innumerable obstacles to the progress of this investigation have presented themselves but sufficient data have accumulated to justify the announcement of a few interesting points.

The matings have been made for the most part at an isolated mating station on the Gulf Coast prairie about forty miles northwest of Houston Texas. The location of the station is almost ideal for this purpose for there are no trees or shrubs affording shelter for bees and no bees occur except those purposely taken to the mating station.

The matings thus far have been confined to crosses between the Italian and Carniolan races. As is well known the pure bees of the former race are distinctly yellow while those of the latter are more or less gray but always when pure devoid of yellow color. For the

¹Abstract of a paper read before Section G of the American Association for the Advancement of Science at the Philadelphia meeting by Professor J. C. Bose.

primary crosses stocks were selected which had been under observation for several generations without having shown any indication of impurity

Pure Italian queens mated to Carniolan drones produce workers and queens which are indistinguishable, so far as color is concerned, from the parent Italian stock that is, in the F_1 generation of this, the "primary," cross, the yellow color is completely dominant. In the reciprocal cross, in which Carniolan queens are mated to Italian drones, the yellow color is also dominant but not as completely so as in the primary cross the F_1 queens and workers show nearly but not quite as much yellow color as the parent Italian stock. The significance of this in practical bee-breeding is at once apparent. For years professional queen breeders have assumed that if an Italian queen throws workers which show the typical Italian coloring it is *prima facie* evidence that she has been purely mated. From the above results it is evident that such is not necessarily the case, for such a queen might have mated to either an Italian or Carniolan drone (or even presumably, to a black drone), and in either case her workers would have the typical Italian color. The purity of an Italian queen's mating therefore can not be determined by an examination of her workers. Further reference to this is made below. The production of yellow workers by a pure Carniolan queen on the other hand, immediately stamps her as having been impurely mated.

There is also excellent evidence as to the inheritance of characteristics other than color. For example the marked proclivity of the Carniolans to use wax instead of propolis for sealing crevices, fastening frames together, attaching hive-covers to frames, etc., comes dominantly to the surface in the F_1 generation of the primary cross. In the F_1 generation of the reciprocal cross this trait is also much more in evidence than in the pure Italian race, though not as completely dominant as in the case of the primary cross.

It seems to be a well-established law of heredity that an individual always produces gametes of the same kind as those of which

it is itself composed. With this law the queen-bee appears to comply without exception. As the drone is produced parthenogenetically he is essentially a gamete and behaves as such in inheritance at least so far as the color factor is concerned. Pure Italian queens mated to Carniolan drones produce only Italian drones, and Carniolan queens mated to Italian drones produce only Carniolan drones. This is strictly in accordance with the theory of Dzierzon. However, the daughters of Italian queens which have mated to Carniolan drones produce both Italian and Carniolan drones in equal numbers, and do not produce any other kind. The F_1 queens of the reciprocal cross likewise produce drones of these two kinds and in equal numbers. This is in accordance with the theoretical expectation under Mendelian law. If the constitution of a pure Italian queen be represented by II and of a pure Carniolan queen by CC the former will produce gametes I and I and the latter gametes C and C, these being Italian and Carniolan drones respectively. A hybrid queen, however, has the constitution IC and produces gametes I and C in equal numbers, these of course materializing as Italian and Carniolan drones. The practical application of this is that the only test of an Italian queen's mating is found in the color of the drones produced by her daughters.

Another interesting consideration is that the production of an F_1 drone seems to be an impossibility and this, in turn, makes the production of a strict F_1 generation look like another impossibility. Beekeepers will at once argue that drones intermediate in color occur in nature, and such is the case. However drones from purely mated queens are known to vary widely in color and this may possibly explain the occurrence of intermediate coloring. We are still in ignorance regarding the causes of this variation, and it is hoped that further data from the mating station will throw more light on this as well as on other phases of this interesting problem.

WILMON NEWELL

COLLEGE STATION, TEXAS,
December 18, 1914

TILLITE IN NEW HAMPSHIRE

IN 1910 while spending the summer at Sugar Hill, New Hampshire, I came across a formation which appeared to me to be tillite. The Rev S S Nickerson, of Sugar Hill had a glacial boulder of conglomerate near his house which looked as if made up of glacial pebbles. Mr Nickerson described an exposure of conglomerate which he had seen in Lyman, 12 miles west of Sugar Hill, several years before I visited this locality with Mr Nickerson. The best outcrop found is about half a mile north of Young's pond by the side of a little schoolhouse in the town of Lyman. I examined the formation and was immediately impressed with its glacial appearance. There was no stratification and the included rock fragments of various kinds scattered through an argillaceous matrix were of all sizes up to 6 feet in diameter. There were very few rounded pebbles most of the fragments being angular and subangular. Here and there large masses of slate, greatly contorted, were found. One of them measured 6 feet long by 4 feet wide on the two exposed dimensions. These slate masses were so like the slate lumps found by me in the Squantum tillite near Boston,¹ that I could not avoid the conclusion that this formation might be tillite also.

On account of the very great shearing and distortion which these rocks have undergone—much greater than the Squantum tillite has been through—it will be impossible to hope for any signs of striations. Even the concave fractures so common on glaciated pebbles in till, and in the Squantum tillite, have been rendered unrecognizable. The general appearance of the rock and the distorted slate fragments are the only criteria so far found to determine the origin of this formation, and the prospects are not very bright for finding any very definite proof. To a glacial geologist, however, the appearance of the rock is almost conclusively glacial.

The thickness of this till-like section can not be less than 100 feet and is probably much

greater. The eastern contact rock is an argillaceous schist with a northeast and southwest strike and a thickness of over 1,000 feet. On the west the contact rock is conglomerate, with water-worn pebbles and some signs of stratification. The thickness of this conglomerate is uncertain, probably several hundred feet.

A few days after the examination of this section I found the "Geology of New Hampshire," by Charles H Hitchcock, in the small library at Sugar Hill. On page 303, of Volume 2 the following description of this rock is given:

"There is a curious conglomerate west of Rev C Corning's in North Lyman, lying adjacent to the Lyman group and supposed formerly to constitute a part of it. It resembles a mass of common drift, because the pebbles are so numerous and, miscellaneous arranged. They consist of both the white and green schists and dip south 52° east. The pebbles are mostly of large size one measuring 2 feet long and 5 inches wide. On the top of Mormon Hill, nearly two miles east of this exposure I found a very coarse conglomerate with strike N 58° E lying on the northwest side of clay slates dipping N 47° W. It is probable that these two exposures belong to the same formation which runs athwart the Lyman group, and may possibly join a very coarse supposed Helderberg conglomerate in Littleton to be described presently."

These words were written long before the word "tillite" had been introduced by Professor Penck, and before the idea of rocks with a glacial origin had entered the minds of American geologists.

In the summer of 1911 I invited my friend, Dr F H Lahee to investigate with me in this region, for the purpose of finding out, if possible, the age of the formation under discussion. He spent two summers making a careful field study of all the formations. The main results of his work, without a discussion of the rock described in this paper, were published by him in the *American Journal of Science*, Vol. XXXVI, September, 1913, "Geology of the New Fossiliferous Horizon and the Underlying Rocks, in Littleton, New Hampshire." The age of the supposed tillite is still much in doubt, on account of faulting and unconformity. Professor Lahee thinks the

rock older than Permian Hitchcock in his first writings on this region called the formation Huronian but 30 years later referred it to the Cambrian or Ordovician. In his later opinion, however, he was not sure.² Further work will be necessary on this most difficult locality to place all the formations in their proper stratigraphical positions.

HARVARD UNIVERSITY

THE PHILADELPHIA MEETING OF THE AMERICAN ANTHROPOLOGICAL ASSOCIATION

THE annual meeting of the American Anthropological Association was held at the University Museum, Philadelphia, December 28-31, 1914, in affiliation with the American Folk Lore Society and Section H of the American Association for the Advancement of Science. The attendance was satisfactory and a rather extensive program was presented. It was decided to hold a special session in San Francisco, August 2-7, and to empower Professor A. L. Kroeber, of the University of California, to make all arrangements relating to the meeting. A decision as to the place of the next annual meeting was referred to the executive committee. The secretary of the Committee on Phonetics, Dr. E. Sapir, read the committee's report in abstract, and the members were instructed to publish the entire report in whatever form seemed most appropriate.

The following officers for 1915 were elected by acclamation:

President F. W. Hodge, Bureau of American Ethnology
Vice-president, 1915 Clark Wissler, American Museum of Natural History
Vice-president, 1916 A. L. Kroeber, University of California
Vice-president, 1917 George B. Gordon, University of Pennsylvania
Vice-president, 1918 Berthold Laufer, Field Museum, Chicago
Secretary George Grant MacCurdy, Yale University
Treasurer B. T. B. Hyde, New York City
Editor Pliny E. Goddard, American Museum of Natural History
Associate Editors J. R. Swanton, R. H. Lowie
Executive Committee A. M. Tozzer, E. Sapir, W. J. Fawkes

² (1) Hitchcock, C. H., "Geology of New Hampshire," Vol. 2, p. 50, 1877, and (2) "Geology of Littleton, N. H.," reprint from the "History of Littleton," pp. 11 and 29, 1905.

Council F. W. Putnam, F. Boas, W. H. Holmes, W. J. Fawkes, R. B. Dixon, F. W. Hodge, C. Wissler, A. L. Kroeber, G. B. Gordon, B. Laufer, G. O. MacCurdy, B. T. B. Hyde (ex officio), A. E. Jenks, A. Barrett, W. Hough, A. Hrdlicka, A. M. Tozzer, F. G. Speck, A. A. Goldenweiser, E. A. Hooton, A. V. Kidder, F. C. Cole (1915), Byron Cummings, G. H. Pepper, W. C. Parabee, I. R. Swanton, G. G. Heye, H. J. Spinden, T. T. Waterman, C. M. Barbeau, W. D. Wallis, A. B. Lewis, Stansbury Hagar (1916), W. C. Mills, H. Montgomery, C. B. Moore, W. K. Moorehead, C. Peabody, C. C. Willoughby, T. Michelson, A. B. Skinner, M. H. Saville (1917), A. C. Fletcher, P. Bowditch, S. Culm, R. H. Lowie, C. H. Hawes, E. Sapir, N. C. Nelson, H. Bingham, J. A. Mason, G. A. Dorney, E. W. Gifford (1918).

The sectional committee of Section H recommended the names of twenty-eight members for fellowship and the council of the American Association for the Advancement of Science duly elected them. The recommendation of the sectional committee that Professor George M. Stratton of the University of California be elected vice-president of the section for the ensuing year, was likewise approved by the general committee. Professor L. Witmer was elected a member of the council, Dr. P. E. Goddard a member of the general committee and Professor F. Boas a member of the sectional committee to serve five years.

The American Folk Lore Society reelected Dr. P. E. Goddard president and Professor C. Peabody secretary, and elected A. B. Skinner assistant secretary.

The address of the retiring vice-president of Section H, Professor Pillsbury, on "The Function and Test of Definition and Method in Psychology" will be published in *SCIENCE*. Dr. Goddard's presidential address before the Folk Lore Society on "The Relation of Folk Lore to Anthropology" will appear in *The Journal of American Folk Lore*.

A number of the papers presented dealt with problems of general interest. Geheimrat Professor Felix von Luschan, who appeared as a guest of the Association, delivered a lecture on "Convergency." He dwelt on the importance of this originally biological concept in the field of anthropology, where both somatological and cultural resemblances can often be ranged in this category rather than under the caption of independent development. Dr. A. B. Lewis, in his paper on "Some Native Industries from New Guinea," passed from a descriptive account to significant remarks on the process of diffusion, as indicated by Oceanian data. The distribution of certain techniques in this area points not so much

to either independent origin or wholesale borrowing, but rather to stimulation of new specialization on the basis of the diffusion of general ideas. The ever vexing problem of historical unity or diversity of origin led to a clash of opinions in the linguistic field. Dr Sapir, in a paper on "The Nadene Languages," sought to establish the genetic connection of Tlingit, Haida and Athapascan. This led to a methodological discussion by Drs Boas and Goddard, who assumed a skeptical attitude. A significant contribution to archeological chronology was presented in Mr N C Nelson's "Chronological Data on the Rio Grande Pueblos." The data pointing to a difference in age of the ruins concerned are to some extent of an architectural nature, but the main line of evidence consists of no less than four distinguishable types of pottery in distinctly stratified refuse deposits. "The Knowledge of Primitive Man" was dealt with by Dr A A Goldenweiser. It is true, he contended, that primitive man has developed theories that seem to differentiate him sharply from civilized humanity—a fact strongly urged by Lévy Bruhl. But it must not be forgotten that in addition primitive man possesses a far from inappreciable body of technical, astronomical, biological knowledge that forms the foundation of our own sciences and should become the object of more systematic study by ethnologists. In another paper Dr Goldenweiser suggested a definite "Sociological Terminology in Ethnology," of restricted range. Professor Boas called attention to the fact that a definite nomenclature tends to hide real problems while specific misgivings as to some of the speaker's suggestions were voiced by Drs Sapir and Lowie. In a lecture on "Exogamy and the Classificatory System" Dr R H Lowie adduced North American evidence corroborative of Rivers's theory that the so called classificatory system, or rather the merging of collateral and lineal lines of descent, is a function of exogamy.

The following additional papers were presented. James R. Nies, "Anthropological Evidence contained in some Cuneiform Signs," Charles Peabody, "Notes on Prehistoric Palestine and Syria," Byron Cummings, "Kivas of the Cliff Dwellers in the San Juan Drainage," George G. Heye and George H. Pepper, "The Exploration of a Delaware Burial Place near Montague, N. J.," Stansbury Hagar, "The Maya Day Sign, Manik," R. B. Dixon, "Statistics Relating to the Vitality and Fecundity of the American Indian Obtained by the Last Census," A. B. Lewis, "Prepared

Human Heads from New Guinea," A. M. Towner, "The Excavation of a Pre Aztec Site in the Valley of Mexico," id., "The Work of the International School of Archeology and Ethnology in Mexico for 1913-1914," Hiram Bingham, "Types of Machu Picchu Pottery," id., "Problematical Stone Objects found at Machu Picchu," id., "Results of Investigations Concerning the History of Machu Picchu," Marshall H. Saville, "Preliminary Account of Archeological Researches along the Pacific Coast of Colombia," Adela Breton, "Some Pages from the Memorial of Tepetlaoztoc and the Painted Map from Metaltoyuca in the British Museum," F. Boas, "Demonstration of a Map showing the Dialects of the Salish Languages," George Hempl, "The Origin of European Alphabetic Writing," H. J. Spinden, "Nahuatl Influence in Salvador and Costa Rica," Stith Thompson, "European Tales Among the North American Indians," Phillips Barry, "The Magic Boat," C. H. Hawes, "Dartmouth College Ethnological Collection," F. G. Speck, "The Eastern Algonkin Wabanaki Confederacy," F. W. Waugh, "Some Comparative Notes on Iroquois Medicine," T. Michelson, "Notes on the Stockbridge Indians," id., "Problems in Algonquian Ethnology."

The following papers were read by title. Robert B. Bean, "The Growth of the Head and Face in American (White), German American, and Filipino Children," id., "Some Ears and Types of Men," G. G. MacCurdy, "The Passing of a Connecticut Rock Shelter," W. J. Wintemberg, "An Iroquoian Site in Eastern Ontario," Robert Gorham Fuller, "Observations on a Series of Crania from the Stone Graves of Tennessee," A. L. Kroeber, "Eighteen Professions," William H. Holmes, "The Place of Archeology in Human History," C. Wissler, "The Diffusion of Modern Ceremonies in the Plains Area," id., "Types of Clothing and their Distribution in the Plains Area," Reed Smith, "1914 Additions to the Traditional Ballads in the United States," C. M. Barbeau, "Huron Wyandot Mythology," Middleton Smith, "The Psychology of Humor, Wit and Riddle," Charles W. Furlong, "The Tribes of the Fuegian Archipelago," A. B. Skinner, "Ethnology of the Eastern Dakota," J. R. Swanton, "The Creek Clans and the Square Ground," P. Radin, "On the Relationship of the Languages of Mexico," id., "Literary Aspects of North American Mythology."

THE ECONOMIC TREND OF BOTANY

It can scarcely be successfully denied that the most significant recent advances in American botany have been along economic lines. By many of our younger botanists the dominance of the practical point of view is taken for granted, but to some of our older investigators and teachers the changing attitude has brought something of a shock. And there are a few who are not yet conscious of the great economic tide which is engulfing us. For the sake of this last group it will be well to consider briefly a few historical facts. As yet within the memory of the older living botanists American botany was scarcely more than the taxonomy of the vascular plants. In the eighties we began importing the laboratory method from Europe particularly from Germany. It was the psychological moment and naturalization took place with surprising swiftness. At first, the new movement found expression mainly in the direction of morphology and anatomy. By the early nineties, however, a pronounced physiological trend found large place and in the late nineties ecologists began taking the laboratory method to the field.

No attempt will be made to picture here the rise of economic botany. It may be pointed out merely that in our older programs it had very little place. A somewhat notable exception to this is afforded by medical botany which has long been paid attention to by botanists. Indeed,

Address of the vice president and chairman of Section G, Botany, American Association for the Advancement of Science, Philadelphia, December, 1914.

MS intended for publication and books etc. intended for review should be sent to Professor J. Mahalanobis (Attell) Garrison on Hudson N. Y.

botany almost began with an attempt to find the cures for human ills. So it was natural enough that posts of botany in the olden time should be assigned so generally to physicians, and that so many physicians should cultivate botanical science. Even to-day, in many European universities botanists who know nothing of such things are often obliged to give lectures along these lines to medical students.

It is only a few years ago that our botanical programs were made up almost entirely of the reports of investigations in what we are accustomed to call pure science, as though applied science were impure. But see what we have to-day! It is a conservative estimate to say that three fourths of our botanical investigation is now along economic lines, as compared with essentially none at all, when the oldest among us were beginning botanical research.

If one were to count the titles in the present program of the Botanical Society of America, he might be inclined to dispute this statement, but it must be remembered that the majority of the economic papers are now given in the various technical societies. Immediately previous to the formation of the American Phytopathological Society, approximately half of the titles offered in the combined programs of Section G and the Botanical Society were phytopathological. If we take account of the work done by the various divisions of the United States Department of Agriculture and by the many state agricultural colleges and experiment stations, by workers in bacteriology and plant breeding, and by investigators in the forest service, it will be realized that more rather than less than 75 per cent. of our botanical investigation is economic.

Whatever may have been the scientific deficiency of much of this work in the past

and of part of it to-day, it must be admitted that there is coming from these sources an increasing body of work of the highest value scientifically. This is well indicated by the *Journal of Agricultural Research*, which from the first number has taken rank with our best botanical journals.

It is scarcely to be supposed that economic botany is a passing fad, and that pure botany, as we call it, will once again come into a place of dominance. The shifting emphasis in botany is but a part of a great movement as broad as humanity itself. The three sections that have been most recently organized in the American Association for the Advancement of Science are practical rather than theoretical, and the last of these, agriculture, is one which is looming up everywhere as a competitor of botany. Chemistry and physics also are being swept with the same economic tide.

No better index is to be seen of the trend of the time than in the curricula of schools and colleges. Once the central feature of our educational system was the disciplinary study of the classics. Latin and Greek, subjects which survived the barbarism of the middle ages and the changing viewpoints of subsequent centuries, have given way before our modern demand for culture that is practical; and it is doubtful if they can ever again take a leading place in educational systems. In many of our secondary schools botany has given way, and perhaps permanently, to agriculture, and in many others agriculture is introduced along with botany, or the demand is made that botany be made practical. Naturally the last institutions to feel the press of the new movement will be the private or endowed institutions, such as the University of Chicago, from which your speaker comes. But even we are feeling it. An increasing number of our stu-

dents are demanding more practical courses or are going elsewhere through failure to find them with us and what is more an increasing number of schools are demanding teachers with more practical training than we have been supplying. Last summer one of our graduates well trained in theoretical botany was offered a position if she could teach agriculture. Fortunately we had imported a professor of agriculture for the summer and the young lady took a hurried course and secured the position. An increasing number of opportunities are offered to qualified students prepared to take up work in agricultural colleges and experiment stations and a relatively decreasing number of places are available in theoretical botany.

If the situation above depicted is a general movement rather than a passing whim it is evident that in many of our institutions botany to remain a living force must change its methods. It may as did Latin and Greek stand inflexibly for past ideals and decline or it may adjust itself to present day problems and live with increasing vitality. We must not be deceived by the fact that more of us than ever before are engaged in the pursuit of theoretical botany. It is not a question of absolute but of relative numbers and by that test theoretical botany is losing. For one I mourn the passing of Greek and Latin. To me those languages have been immensely practical and I do not at all regret the seven years I employed in their study. Yet how much better off we all would be had the classics as we took them been related to our modern life! And they might have been so related, for there are many points of contact but your teachers and mine held rigidly for classics for the classics' sake and for disciplinary values, and it is for this that they have fallen.

At Chicago we still adhere to the ancient notion that the A.B. degree should stand for training in the classics and the result of course is a great decline in A.B. graduates. Some convocations pass without a single student taking that degree. One day I asked one of our professors of Latin if the slump in Latin and Greek were general and permanent or merely local and temporary and he replied with sadness. I feel that it is world wide and lasting even Oxford feels it. Almost the only ray of hope for us is that the botanists still require the diagnoses of species to be in Latin.

It would be a world tragedy if theoretical botany should die or even if it were to be less influential than it is at present. It is vastly more important than are Greek and Latin and yet their decline is to be contemplated with profound regret. But botany is the foundation of agriculture and agriculture is the most fundamental employment of the human race.

To be sure we can farm without being botanists but we can not farm so well. Through the ages agricultural man has stumbled on many important facts and principles that the botanist has later on explained thus making more scientific farming possible. Witness the enrichment of land by growing leguminous crops—a fact mentioned by Pliny and explained by modern botany and as a result utilized with vastly increased success by the present-day agriculturist. Witness too, the history of our knowledge of the wheat rust, or the recently discovered hereditary symbiosis of bacteria and seed plants—phenomena seen by agriculturists as in a glass, but very, very darkly until the theoretical botanists explained them.

In spite of these instances and a hundred more the practical man is coming increasingly to look with scorn upon the

theoretical botanists. What matters it say we? Alas it matters much unless we happen individually to be endowed. For botanical positions like other things in life are controlled by the law of supply and demand. In more than one institution that I know the tenure of position of the botanist depends upon his success in attracting students. The student needing bread and butter will not be attracted to lines in which he can not earn it and as Mr Dooley says "Here ye are." In several state universities the clash has already come and in every case of which I am cognizant the more practical botany of the agricultural department has won as against the more theoretical botany of the academic department. Even in our private institutions we commonly have practical trustees who sooner or later may see the trend of the time and act accordingly.

Notwithstanding the sorry picture just painted I suspect that all of us believe at heart that the most fundamental aim of botany is the improvement of the human race. All of us desire as our supremest wish that we may do something in our brief life to make man's lot better than before we came. Therefore it remains only to make concrete our inmost ideals in order to save the day for botany as it was not saved for Greek and Latin.

A good many years ago I published a paper on the vegetation of the sand dunes of Lake Michigan depicting the principles of plant succession as there so strikingly illustrated. Shortly after with an expression on my face betokening "There now isn't that something like?" I gave a copy to a man of the world who said merely "Well what of it?" Aghast I said nothing and only now, fifteen years afterwards, is the answer forthcoming. It is as follows:

Two years ago I was surprised to receive

a message from the United States Department of Justice asking for my services as an ecological expert in some government cases in Arkansas. With many misgivings and with the feeling that ecology as I represent it was now specifically on trial I took up the work assigned me. To my unalloyed gratification I discovered that matters which perplexed the Department of Justice were simple enough when examined by an ecologist rather than by an attorney. In 1847 the original survey was made by the United States of the bottom lands along the Mississippi River in eastern Arkansas and the country was opened for settlement. A great deal of the area was surveyed as permanent lake and is so shown even on the most recent detailed maps. At the present time these so-called lakes are completely heavy timber of great value. Furthermore this lake land is very fertile and much in demand for raising corn and cotton. However as it is termed lake in the original survey it can not be homesteaded and farmed. A few years ago riparian lumber interests having used up the high grade timber on the surveyed lands looked with envy on the splendid timber growing in these so-called lakes. Consequently they conceived the idea of purchasing riparian rights from the owners of the adjoining surveyed land and they proceeded to cut the timber. Shortly afterwards the United States government instituted suit against these lumber interests its contention being that the original survey was fraudulent that lakes did not exist in 1847 and that riparian rights therefore did not inhere. In the meantime pending settlement provisional entries were made by squatters. While test suits were made on only a few of these so-called lakes there exist many tracts of similar nature involving in the aggregate

many thousands of acres and property values up into millions of dollars.

As an ecologist it was my duty to determine from present indications the nature of these so-called lakes in 1847. The work was ridiculously easy, since it was found that these "Lake beds" were covered with upland timber of great age. The attorneys for the lumber interests endeavored somewhat half heartedly to show the inaccuracy of the method of determining the age of the trees by a count of the annual rings, but in the face of the hundreds of years of age shown by many of the ring counts, this contention had short shrift.

Somewhat greater efforts were put forth in support of their claim that trees can grow in lakes, much being made of the well known fact that the bald cypress, *Taxodium distichum*, occurs in well defined bodies of water. It was here that the ecological argument had its greatest force. Having visited the country of the lower Mississippi on two previous occasions and having made four trips to the territory in question during the course of my work for the government, I was in a position to know the main facts in the ecological succession on the Mississippi bottoms.

Employing the happy terminology of W. S. Cooper, there are two types of hydrographic succession in the area in question, that from the river and that from the lakes which generally are back of the levee or in old cut-offs due to a shifted course of the river. On the river front, as the alluvium is built up, there is frequently seen a sandbar vegetation of ephemeral annuals associated with low summer levels of the river. Back of this there appears the first ligneous vegetation, dominated usually by willows, such as *Salix longifolia* and *S. nigra*. Further back there appear more or less definite stages of vegetation, each stage associated with a water table of a

given depth, culminating in the great river-bottom forests of *Quercus texana*, *Q. lyrata*, *Acer rubrum*, *Liquidambar*, *Celtis*, various hickories, *Populus deltoides*, *Ulmus*, *Platanus*, *Frazinus americana*, and the like. It is probable that this forest type is not the permanent climax of the region, but rather a very long enduring temporary climax.

In the lakes, whether formed by the elevation of natural or artificial levees or through the shifting of the river channel, the course of vegetational development is somewhat different. At first there is a pond vegetation with *Nelumbo* and other pond aquatics. Following this one finds at times a flag grass prairie or again a willow belt much like that of the river front. The most striking feature of these lake successions, however, is the stage dominated by the tupelo, bald cypress and water locust, which usually follows the willow or prairie stage. As shown by the great age of the trees (tupelos of 200 years, and cypress of 700 years having been observed) this stage may last for a long time.

It is particularly important to note that many tupelo and cypress trees were seen to have been killed by submergence during periods of high water, thus showing that these trees are properly trees of the land rather than of the water. If they occur in lakes, as they do, this fact would seem to indicate that the lakes are but temporary, or at least that there were only short periods of particularly high water during their early life. After these trees there comes a forest of red maple, sweet gum, pumpkin ash, planer, pecan, etc., and then again after a lapse of many more years there comes the characteristic forest of the so-called lakes, the temporary climax forest above noted, with its gigantic oaks, hackberries and other trees of the dry ground, therefore, when one cuts an over-

cup or Texan oak and finds it to have an age of 300 years, it is clear from these facts of ecological succession that it has been much more than 300 years since there was a lake, where the trees now are.

Through a study of trees that germinated on these lands in and about 1847 I was able to determine that at that time the conditions were essentially as at present, since in the so called lake beds the same species of trees are developing now as in 1847. I testified that in the lands in suit the evidence of ecological succession shows beyond all question that even a thousand years ago these so-called lakes must have been land and it is my firm belief that there have been no lakes in these sites for at least two thousand years.

The physiographic evidence corroborated the ecological evidence in striking fashion. It is a well known fact that deposit is more rapid on the immediate banks of the Mississippi than farther back, much coarse material being deposited near the shore, whereas further back the material is finer and finer and constantly less in amount. It is this fact that accounts for the formation of the natural levees, thus in these so-called lakes which mostly lie some miles back of the river front, the alluvial accumulation is slight. It is mostly to the much slower accumulation of vegetable material that they owe their gradual elevation above the water table. Excavations near the river and in the so called lakes brought out this difference most strikingly.

Furthermore, the spur roots which are sent out at the ground line are still uncovered by accumulated alluvium, even on the oldest trees. Had lakes existed in 1847 and been subsequently filled by detritus, it is clear that the spur roots of old trees would be deeply buried. In the so called lake beds there are many logs of trees that fell in the earthquake of 100 years ago,

and even these logs are still unburied, thus showing an absence of appreciable alluvial accumulation for at least a century.

Two questions may have occurred to you that are more of human than of ecological interest. What was the object of a fraudulent survey of such colossal magnitude, and how were the suits decided? As to the motive of the surveyors, it may be noted merely that in 1847 our government surveyors got a certain sum per mile for ordinary surveying, and considerably more for surveying lake shores because of the greater difficulties involved, it was an object to return lakes even if the meander lines had to be traced while in camp. As to the decision of the suits, the district judge at Little Rock in the first test suit, made a sweeping decision in favor of the government as against the lumber interests, though an appeal has been taken to the higher courts. It may be interesting to note that the judge based his decision largely on the ecological facts, in the face of testimony given by some of the oldest inhabitants that they had actually seen the lakes in question! However, other equally old and perhaps more respectable inhabitants testified that conditions in 1847 were essentially as they are to day. It was brought out in court that it is safer to believe a tree than a man! Thus a line of investigation which we had supposed to be theoretical only has turned out to have large practical significance.

No claim is made of course, that this is the first demonstration of the utility of ecology. A field of research of almost limitless possibilities is indicated by Shantz's splendid paper on the natural vegetation as crop indicators in the Plains. Just as untold sums of money have been wasted in the search for gold where the geological formation is such that the pres-

ence of gold is impossible, so countless amounts of time and money have been squandered in agricultural experiment on land whose natural vegetation, if studied, would have directed other uses. One of the best applications of ecology is afforded by the work of Coville, on the culture of the blueberry, of which we are to learn something more to day. The utilization of acid lands by the growth of crops that thrive in the presence of certain organic acids is a large conception and will doubt less prove to be one of the great utilitarian discoveries of our day.

I will not trespass on your time by indicating further practical applications of my chosen field ecology. Others will suggest themselves as will similar applications in various lines of botany, particularly in physiology. If we are to keep botany alive and abreast of the time, we who are in academic botanical departments must give more attention than formerly to the economic aspects of our subject. We must offer more courses in the practical phases of botany. In our research we must not avoid practical problems but look for them and we must emphasize the practical possibilities of our theoretical problems. Our sister science zoology, which perhaps is in a more serious plight than we, gives evidence at this meeting of an attempt to meet the situation by choosing for its symposium the significant topic "The Value of Zoology to Humanity." Above all we must treat the economic relations of our subject, not as an annex, a thing apart a "sop to Cerberus," but as the vital and essential thing, the very kernel of it all. By pursuing such a course we shall keep in close relationship with our practical modern life, and we shall justify ourselves to our fellows. We shall then have ample opportunity to continue our researches along theoretical lines.

And one may never know how soon a purely academic study may come to be a factor of the first importance in the betterment of the human race.

UNIVERSITY OF CHICAGO

CONSERVE THE COLLECTOR

It is with considerable apprehension that I have observed an unmistakable decrease in the number of collectors during the past six or eight years. Matters of precision and accuracy in the field of ornithology are, I have no doubt suffering as a consequence of this forsaking of the "shotgun method." Our faunistic literature to be of the highest scientific character must be based on the surest means of establishing the identification of species. The "skin record" is essential, and the availability of this is dependent upon the existence and activity of the collector.

The type of field observer who depends solely on long range identification is becoming more and more prevalent. But the opera glass student, even if experienced, can not be depended upon to take the place of the collector. Accuracy in identification of species and especially subspecies rests for final appeal upon the actual capture and comparison of specimens. Ornithology as a science is threatened, and it should not be allowed to lapse wholly into the status of a recreation or a hobby, to be indulged in only in a superficial way by amateurs or dilettantes.

It is to be doubted whether authoritative and expert systematic and field ornithologists can be developed through any other process than by personal collecting of adequate numbers of specimens in the field. The processes of hunting and personal preparation of bird skins bring a knowledge of the characters of birds, both in life and as pertaining to their structure and plumage, which can be secured in no other way.

The present tendency toward extermination of the collector bears obvious close relationship to the increasing number of extreme sentimentalists. The latter, beginning in a

good cause, now continue to urge stringency in state and federal laws beyond all reason. Those in authority "high up" ought to know better than to contribute to this stringency, but they, yielding to the pressure of the militant sentimentalists, are allowing laws and regulations to go through without giving apparently any thought to their duty toward the field naturalist whose function is essential to the conduct of important phases of ornithological study.

Permits should be issued by both state and federal governments freely to applicants upon avowed sincerity of purpose. There should be no hesitation unless there be suspicion as to the honesty of the applicant. Limitations may be properly imposed, as for instance by excepting rare or disappearing species like the ivory billed woodpecker or the Carolina parakeet. This is just as feasible as it is to forbid the sportsman to shoot rare or disappearing game species. Furthermore, the collector by reason of his more expert knowledge, is far better able to discriminate between closely allied species and because of his appreciation of the facts upon which the principles of conservation are based, is more likely to abstain from killing the wholly protected species. As a rule, the birds which particularly interest the collector consist of small species of wide distribution and large numbers. And the daily "bag limit" of the collector, self imposed because of the subsequent labor entailed, is small, seldom exceeding 20 birds all told and, in my own experience, averaging 12.

Collecting, at best, will be indulged in by but comparatively few people, for it involves much more effort than hunting, the successful collector must possess a considerable equipment in the way of industry and artistic skill if he expects to reach recognized standing in the fraternity of collecting ornithologists, and at the outset he must possess the naturalist's gift or "bent" which is itself not common.

It can be rightly urged in this connection that the justification for collecting non-game birds is just as well grounded as for shooting or otherwise destroying *game* animals. Practically all small birds can better stand an

annual toll than most game birds. Owing a single species of non game bird, the Audubon warbler I believe that its numbers within the state of California at the beginning of the winter season exceed the combined numbers of all the species of game birds within the state at the beginning of the open season. Yet for the pursuit of game birds over one hundred and thirty thousand hunting licenses were issued last year here in California alone. In the same state only one hundred permits for scientific collecting were allowed, or only one permit to collect non game birds to 1,300 licenses to hunt game birds! Most of these permits were limited to two specimens of a kind, and in many cases they were given out grudgingly or under protest, as if the collector were seeking something beyond his rights to ask for, or even as if a question of morality were involved! This again is an attitude (on the part of *sportemen* which our State Game Commissioners all are!) hardly consistent, but evidently resulting from the wide spread influence of the sentimentalist.

As compared with the value of the game bird shot, does not the bird killed for a specimen come much more nearly justifying its end? The game bird practically ends its career of usefulness when it falls before the gun. It has incited recreation and a certain amount of the esthetic in the way of admiration. Perhaps the latter obtains for a few minutes or hours after the death of the bird. But it soon goes to pot and that is the end of it.

With the bird hunted for a specimen, the collector is searching discriminatingly among many species and often among a great many individuals. He is observing many things beyond the mere object of the shot. In addition, full recreative value is being obtained as in the case of game (and this is generally urged now a days as the value of game—in its service, not as food, but as an object of pursuit and contemplation before killing). The value of a bird shot for a specimen does not end with its death, although it has served the other functions already. The collector prepares the bird with painstaking care, at

the same time acquiring added information, and installs it under safe conditions as an object of study and appreciation for all time. Instead of being merely eaten it becomes a joy forever.

To my mind there is no more practical reason for shooting a snipe for sport than for shooting a Savannah sparrow for a specimen.

My thesis is not that hunting game for sport is unjustifiable but that hunting both non game and game birds and mammals for specimens is at least equally justifiable. The state and federal warden system should be revised so that the collector and the sportsman shall be treated on the same basis. That is all I am pleading for. The laws and those officers whose duty it is to interpret and enforce them should *allow* collecting and regulate it just as is done in the case of hunting. Those in high official position should recognize the claims of the private collector as well as the claims of the sportsman. We are responsible one to another for looking after each other's interests. Those at the top should have a care for the privileges of their minority constituency wherever such privileges be not in serious conflict with the interests of the majority.

A further instance of inconsistency is to be noted in the intemperance with which the reservation idea has been put into effect within the last few years. The whole scheme of game refuges and the reservation of restricted areas for safe breeding grounds for birds is a splendid one. Its adoption on a large scale is a thing worthy of the deepest satisfaction on the part of naturalists, economists and sentimentalists alike. But hasn't it gone beyond all reason when the Aleutian chain of islands is closed absolutely to the collector when St. Lazaria Island, southeastern Alaska, which to my knowledge has been visited by collectors just three times in twenty years is suddenly declared a bird reservation and the regulations so fixed as to completely bar the taking of birds or birds' eggs for bona fide scientific purposes! It seems to me vastly more reasonable economically to put colonies of sea birds under warden control, and at the same time to

give the warden power of *allowing* moderate collecting and to see that such levy on the population is kept within the rate of productivity of the colony. It is exactly the same proposition as the gathering of mature timber from the forest reserve or the shooting of moose and deer within certain safe numbers annually in Maine. A sea bird colony such as that on the Farallone Islands would not suffer in the least if certain numbers of birds or eggs were gathered each year totaling perhaps hundreds just so these numbers were within the annual rate of increase. Such a course is absolutely the opposite of unlimited destruction such as that waged by the plume hunter. The latter violates the principles of conservation which all men of science join with vigor in upholding.

Reasonable attention to several other factors well known to collecting ornithologists would far more than compensate for the toll taken by collectors. For instance on the Farallone Islands the colonies of gulls are on the increase the murres and cormorants are on the decrease in spite of total protection because of the pravity of the gulls. Many of the other birds on those islands would profit to a far greater degree if a considerable proportion of the gull population were eliminated. And this could be done easily through appropriate efforts on the part of a game warden at the beginning of the nesting season.

Collectors themselves probably fully compensate for the number of birds they destroy for specimens in the incidental destruction by them of vermin. Collectors are practically the only people who can and do distinguish between the destructive and harmless hawks. The average collector can and does on all occasions destroy Cooper and Sharp-shinned Hawks and in this way certainly makes up several times over for the small birds he shoots. Suggestive estimates could here be given as to the annual destruction wrought among both game and non game birds by the few injurious species of hawks and owls. The predaceous blue jays also receive the collector's attention.

It is true that collectors in the past have in

some instances behaved indifferently toward people who are sensitive to bird killing. This lack of sympathy on the part of the collector may be one factor that has brought him into disrepute. It is to be deplored. To control the thoughtless among collectors it is feasible to devise and enforce regulations, such as one to establish say a three mile limit around all cities and even villages of a given minimum size. By similar action already taken in some states hunting is prohibited within specified distances of public grounds.¹ A system of local refuges and parks, where shooting for any purpose whatever would be prohibited would certainly be approved by most collectors and would go far toward meeting the wishes of other lovers of living birds.

It should not be forgotten that the collecting ornithologist has furnished the bulk of the reliable data upon which our game laws are based and upon which the economic value of our non game birds has been established. Furthermore the training involved in bird collecting can surely be given some credit in several cases of eminent men of science who are now valuable contributors to science in other fields. The making of natural history collections is useful as a developmental factor, even if dropped after a few of the earlier years in a man's career. Collecting develops scientific capacity: it combines outdoor physical exercise with an appropriate proportion of mental effort both enlivened with the zest of a most fascinating and at the same time widely suggestive line of enquiry.

As a rule, all collecting adds sooner or later to scientific knowledge either directly through printed contributions from the collectors themselves or through the subsequent study of the material by others, often after it has been acquired by some public institution. The ultimate fate of practically all private collections is the college or museum. Very few bird skins, for instance, are destroyed except through fire or other catastrophe. They live on and on, sources of added knowledge and instruction.

In conclusion let me urge that I consider judicious collecting absolutely indispensable

to serious ornithological research along certain important lines: namely, faunistics, systematics, migration, and food studies. There is still an enormous amount of investigation to be done along these lines. Right now progress is perceptibly retarded because the field of ornithology is being avoided or deserted by the younger students. This desertion is often due to difficulties in the way of securing permits and to lack of encouragement on the part of older men. The legal attitude toward collecting should be revised so as to take in the needs and proper demands of the collector, as well as those of the sportsman.

JOSEPH GRINNELL

UNIVERSITY OF CALIFORNIA

THE SCIENTIFIC TREND IN SECONDARY SCHOOLS

A MISCONCEPTION regarding the trend in secondary education seems to have been incorporated in recent educational opinion. From the first citation¹ below there is quoted the following (p. 80) referring to Mr. Fisher's article:²

We note therefore the phenomenon of a decline in the ratio of students who elect science.

There can be no doubt that there has been a decline in the percentage of students electing physics, chemistry, physiography and physiology as Mr. Fisher's graph shows, but that we are to conclude from these data that there is a decline in the sciences and an increase in the humanities is not so certain. It is quite possible that this decline in the enrolment in these subjects is explained by the shift of students with scientific interests to other subjects like botany, agriculture, domestic science, etc. Or it is conceivable that while the enrolment may decline, the length of time devoted to each subject is so in.

¹ Report of U. S. Commissioner of Education, 1913, Chap. V, "The Status of Secondary Education."

² "The Draft in Secondary Education," Willard J. Fisher, *SCIENCE*, November 1, 1912, N. S., Vol. XXXVI, No. 931.

posed that the total time devoted to it by all students remains a fairly constant factor. Combining the data for the sciences, the classics, the mathematics, the history and the English in the table from which Mr. Fisher obtained his data, namely, the "Summaries," on p. 1141 of the Commissioner of Education's "Report for 1910," we get the graph shown in Fig. 1 of this article. The lines

FIG. 1. Diagram shows percentage of total high school enrollment in U. S. taking courses in mathematics —x—, foreign languages —o—, science —, classics — — —, history — — —, and English — · · ·. Data from tabulation, page 1141, Report U. S. Commissioner of Education, 1910. 1 mm = 1.2 per cent.

show the percentage of students taking these various subjects during the period of years from 1890 to 1910, inclusive. As far as the sciences, as a whole, go, it is evident that the data show that the enrolment in the sciences has increased much more rapidly than the enrolment in the classics and more rapidly than anything else in the tabulation except the

English. I am aware that this conclusion is probably as unjustifiable as Mr. Fisher's because the data for the sciences are incomplete and the apparently erratic rise of the science line is due to the continued introduction of new data. Botany, zoology, agriculture and domestic science are apparently only of sufficient importance in recent years in the high-school curricula to have their enrolment reported. Yet the table gives the impression that the decline in physics, chemistry, et cetera is due to the shift of students to these newer subjects.

I have examined with interest later reports of the Commissioner of Education to see if they confirm or contradict the conclusion to which Mr. Fisher comes, namely, that the sciences are declining in popularity with high school students and that the humanities are constantly increasing their percentage of enrolment. But with the report of 1910 the commissioner ceased to print a statement of the enrolment in the various subjects, evidently appreciating the fact that such data in the form in which they had been given, are more or less inconsequential. There is continued, however, the report of those graduates of public and private high schools who are preparing for college and who elect either the classical or the scientific course. These data are shown in Fig. 2. The first part of the chart gives the

FIG. 2. Diagram shows percentage of high school students going to college who select classical — — — and scientific — — — courses. 1 cm = 2.7 per cent.

data for five-year periods, the latter part for yearly periods. Both the dotted line representing the percentage of classic students and

the solid line showing those in science are declining indicating that the percentage of high school students who go on to college is constantly diminishing but in so far as the graph throws light on our problem it indicates that classical studies among high school graduates intending to go on to college have been growing in disfavor more rapidly than the scientific

The apparent increase the country over in the enrolment in Latin and the decrease in physics chemistry physiology et cetera may be due to such changes in restricted regions which are not standing in a position of educational leadership. Such I think is the case and hence I do not believe that the data Mr Fisher uses can show the *trend* in modern secondary education. In the first place the great increase in public high school enrolment has been in the rural high schools. The sort of course in vogue there will determine there fore in large measure the increasing enrolment in the various subjects. Mr Fisher's second chart indicates that the percentage of population in public high schools has increased much more rapidly than the population of the United States but that the rate of increase in urban high schools has been very slow. In other words the drift which his figures might show is a drift that is found in the rural high schools. From 1890 to 1913 the percentage of the rural population (in cities of less than 8 000) attending the rural high schools has risen from 0.15 per cent to 1.40 per cent while the percentage of urban population in urban high schools has only risen from 0.74 per cent to 1.47 per cent. In 1890 the enrolment in rural high schools was only half (50.4 per cent) of that in city high schools in 1913 it was 11 per cent greater. We should hardly look to the rural high schools which have been established in such numbers in the last decade or two, to set the pace in educational matters. The trend in education would be much better indicated by the movements in the larger high schools and in the more progressive states. In the second place in the decade from 1900 to 1910, 59.5 per cent of the increase in high school attendance was

in the North Atlantic states a region still under the dominance of classic ideals in its smaller high schools. This fact would tend to make any reports including these figures show a dominance of the classics. Thus in Connecticut³ the number of students pursuing various branches is given as follows: Modern language 7 586 Latin and Greek 5 947 mathematics 12 070 literature 21 429, science 6 876. In Ohio however the figures are: modern language 7 681 Latin 45 023 mathematics 200 875 literature 61 755 science, 489 412.⁴ Yet one would hardly even accuse New England of leading secondary education away from the sciences to the humanities.

The Ohio State Report (1913) gives comparative figures (p. 13) for a much shorter period than the U. S. Commissioner. I give them herewith for 1909 and 1913:

	1909	1913
Science	467 668	437 974
Latin	42 765	45 023
English	747 813	756 009

The data for New Jersey can be given only for the last two years:

	1912	1914
Science	17 509	22 478
Latin	15 003	13 147
English	28 540	32 230

These citations are not selected. Reports were requested from what seemed a fair sample of states namely N. H. Vt. Mass. Conn. N. Y. N. J. Pa. Ohio Mich. Minn. Ia. Va., Md. Ky. Ga. Ore. Cal. The ones cited are the only ones among these which gave the desired information.

Not many of the states furnish for a period of years data regarding the enrolment in various subjects in the high schools. I give herewith the graph (Fig. 3) of the state of Minnesota showing the percentage of the total enrolment in science, Latin and English. The percentage in mathematics and in the history group has remained at about the

* P. 228. 'Report of the State Board of Education,' 1910-11.

⁴ Ohio School Report, 1913, p. 70-73.

same level Minnesota will be free from the conservative classic tendencies of New Eng-

FIG 3 Diagram shows the percentage of total high school enrollment of Minnesota taking courses in science —, Latin --- and English o o o 1 cm = 3.5 per cent

FIG 4 ENROLLMENT IN SCIENCE — AND LATIN --- in the Galva Ill., High School, expressed in student weeks 1 mm = 33 student weeks.

land and her rural population has increased less than 10 per cent in the last decade

Another bit of evidence comes to hand in the "Report of the Bureau of Research of the Upper Peninsula Educational Association" (Michigan). Not a single high school requires Latin for graduation, three require a language, ten require science, three of these specifying that it must be physics, seven require neither science nor language, six did not report

While these figures are all significant the enrolment in a given subject does not indicate the relative amount of time which is devoted to it. The enrolment, for instance, in a science might be the same as in Latin but the science might continue only for a single semester while the Latin continued for the year. It would be possible, then, to measure the interest in a science group as compared with a language group only when the enrolment is expressed in commensurate terms.

I have had the opportunity recently to examine the records of the high school at Galva, Illinois. During the time covered by the graph given below (Fig 4) the superintendent of schools has remained unchanged. No sudden change in the administration has, therefore affected the curve. The enrolment has been figured in student weeks. Thus, if twenty students take Latin for twenty weeks, the registration of the class would be consid-

ered eight hundred student weeks. The graph given in Fig 4 indicates the enrolment in science and in Latin and it is surprising how the two lines parallel each other. This, of course, is for a single school only, but it is the type of study which must settle the question as to the relative interest in science as compared with other subjects.

ELLIOT R. DOWNING

THE UNIVERSITY OF CHICAGO

PATRONIZING THE SOUTH AMERICAN REPUBLICS

THE report made by Mr. Bard to the trustees of the Carnegie Endowment for Peace¹ describes a tour of South America made by a party of twelve young men from our universities and one naturally inquires what the party proposes to do in behalf of international peace. The purposes of the expedition seem to have been comprehensive—remarkably so in fact—though nothing is said specifically about peace. It is inferred that peaceful ends are to be attained through the cultivation of friendly relations in general and by the building up of North American commerce with South America. Any one who has much personal acquaintance with South American peoples and conditions is necessarily interested in such expeditions.

It is fully realized nowadays that neither persons nor peoples can be friends unless they have some acquaintance with each other and we are bound to think well of any effort that really helps or seems likely to help towards a better acquaintance with our Latin neighbors. But the discoverer of a new country always does well to be modest in his claims and in so far as possible to look at things from the point of view of the country and of the people thus discovered. And really the business of discovering people is a bit risky for the reason that they may not be entirely new nor is discovery altogether flattering to the people discovered. A while ago Mr. John Doe, a distinguished North American, made a trip to South America where he was kindly received and handsomely treated and when he came home he gravely announced that South America was waking up. A gentleman who had known that part of the world for a great many years received the statement with the quiet remark: "I suspect that it is Mr. John Doe who is waking up."

But Mr. Doe's discovery was not the first one nor yet is it the last one. Various societies for the promotion of all sorts of things and boards of trade from all sorts of places, have made the grand tour of South America, visiting the same cities being received by the same people and seeing the same sights and they have all come home with the same story: South America is waking up!

When an organization of such serious purposes as the Carnegie Endowment for International Peace entered the South American field it was supposed that having grown to man's estate we had now put away childish things. But though this last expedition takes itself very seriously indeed the program as given in the published report looks remarkably like the same old thing. The description of the experiences of one of these junketing expeditions is much the same as that of any other. They make known their coming beforehand in the countries to be visited and the program is about the same for one as for another. Greetings are wired back and forth from various stopping places on the way and even while they are yet at sea so that by the time one of the chief cities is reached the whole nation is fairly agog. Arrived in port they are met with special launches by official committees appointed by the government at whose expense they are put up and entertained at the best hotels. Traveling inland they are given special cars and special trains and are met at railway stations by various dignitaries often with bands of music and fireworks. They are driven about in the finest of motors they are shown all the showy sights of the cities they visit, they are taken to the operas at public expense refreshments are served them on all possible occasions they are banqueted and toasted and hear beautiful complimentary speeches and deliver a few themselves, and finally loaded with presents pictures and publications (p. 17) they get back on board their steamers (at government expense again), where they settle down in their comfortable steamer chairs profoundly impressed with their own importance and by the sensations they are evidently creating. And all these manifesta-

¹ "Intellectual and Cultural Relations between the United States and the Other Republics of America" by Harry Erwin Bard. Publication No. 5, Carnegie Endowment for International Peace. Division of Intercourse and Education. 8vo 35 pages. Washington 1914.

tions of the warm hearted, polite and generous hospitality of the Latin peoples our representatives accept as evidences of the "waking up" of South America, and as tributes to our general superiority, sagacity and superhumanity

Thus encouraged, these representatives of ours—these innocents abroad—generally open their hearts and give their hosts the benefit of their wisdom and patronage. In the present case it was suggested to a minister and also to a president that a certain group of teachers would like to visit the United States and the Panama Exposition, "and they seemed pleased with the idea" (p. 12). And such a new idea too and one that would cost so little—to us! Of the city of S. Paulo, Brazil, it is said that the "people show intelligence and purpose in all their movements" (p. 8). How it must please the people of Brazil to be told that they show intelligence and purpose! It is frankly stated that the chief aim of the party was to "make favorable impressions everywhere," and it is believed that the general impressions on both sides were good (p. 20), while everywhere they found eagerness for "closer intellectual and cultural relations with the people of the United States" (pp. 8, 15, 10).

Is it any wonder that the utility of such expeditions is questioned? What do these young men know, and what can they reasonably expect to learn in the few strenuous days spent among them, of the grain, the traditions and the point of view of the people of South America? This particular expedition spent eight days in Brazil, three days in Uruguay, six days in Argentina, nine days in Chile, and one day in Peru—just twenty seven days on the continent of South America! The author of the report lays stress on "the experience and knowledge gained on this trip" (p. 20), while some fear is expressed lest "this golden opportunity for mutual service may pass without profit" (p. 30)—a fear that we cordially share with the members of the party.

Evidently it is not realized by those who are responsible for them that such excursions tend to discredit the very men—their fellow-countrymen—who have lived for years in

South American countries, who must of a necessity form the very groundwork of any future business we can reasonably hope to develop, for they are the ones who have built up good reputations and sound business by right living and right dealing and who do more for North American trade than all the junketing expeditions and drum beating delegations ever sent out either by public or by other organizations whose judgment is not on the proper footing with their good intentions.

Our profound ignorance of Latin America is not to be whitewashed over by such processes, nor are the people of South America of the kind to be taken in with a lot of colored glass beads or palaver.

There are a few fundamental principles that should be called to the serious attention of those who are responsible for such expeditions as this one, or for efforts of any kind to cultivate trade or friendly relations with South America.

First, business relations and business confidence in South America are things of slow growth, just as they are in other parts of the world.

Second, the experience of residents and authorities who have spent their lives in studying and meeting the conditions of commerce and intercourse can not safely or justly be brushed aside and disregarded.

Third, if the people of Latin America are to be patronized and talked down to, our efforts to gain their confidence or to establish cordial relations with them will never meet with any genuine success.

JOHN CASPER BRANNER

STANFORD UNIVERSITY, CALIF.,

January 8, 1915

A NEW FIELD SCHOOL OF GEOLOGY FOR HARVARD UNIVERSITY

At a meeting of the visiting committee of the department of geology and geography held with the members of the staff on January 30, plans were presented and approved for extending the field work conducted by the department during the summer months. Professor Wallace W. Atwood, who recently re-

signed from the University of Chicago to join the Harvard staff, will have charge of this new work, and during the summer of 1915 will establish a camp in the San Juan Mountains of southwestern Colorado. Five weeks of introduction will be given, beginning early in August and closing about the tenth of September, and this course will be credited at Harvard University towards a degree.

The party will be limited in number, and opened only to those men who have had at least an introductory college course in geology. Under the direction of Dr Atwood the party will actually conduct a piece of geological survey work and at the close of the season have the opportunity of an expedition through the high mountain area. The field chosen is remarkably rich in its range of geological phenomena, in mining interests and in scenic features. The equipment of the camp is provided for by funds furnished by the visiting committee of the department which will reduce the cost to each student to his share of the actual living and moving expenses associated with the camp and it is estimated that these expenses will not exceed one hundred dollars for each member.

Applications for membership in this party should be addressed to Wallace W Atwood, Harvard University, Cambridge Mass, before May 1, 1915.

The usual field work offered in Montana and conducted under the endowment of Robert W Sayles and under the direction of Professor J B Woodworth will be offered during the coming summer. That work will begin early in July and close in time to permit those who wish to join the Colorado party. The combination of the two courses permits the student to spend ten weeks under instruction in the Rocky Mountains during the coming field season.

The following members of the visiting committee were present at the meeting when these plans were approved: Messrs George B Leighton, George P Gardner, Guerdon S Holden, Livingston Davis and J Walter Wood.

THE SUMMER MEETING OF THE GEOLOGICAL SOCIETY OF AMERICA

The society has accepted the invitation of the authorities of the University of California and Leland Stanford Jr University to hold a special meeting at Berkeley and Stanford University August 2-7, 1915, in affiliation with the American Association for the Advancement of Science. The following topics have been selected for particular discussion during the geological meetings: (1) Erosion and deposition in arid climates, (2) Diastrophism of the Pacific Coast, (3) Petrological problems of the Pacific area.

The sessions of Monday and Tuesday will be held at the University of California and that of August 4 at Stanford University.

Excursions under the leadership of local geologists will be organized during the remaining days of the week as follows:

Thursday, August 5 to Point Reyes Station, Marin County, for an examination of the San Andreas earthquake rift.

Friday, August 6 to Mussel Rock, San Mateo County by the Ocean Shore Railway, for an examination of Pliocene strata, the type section of the Merced formation and post Tertiary deformations of the coast.

Saturday August 7 two excursions will be provided, one by the Oakland Antioch & Eastern Railway (electric) to Mount Diablo for an examination of the Mount Diablo overthrust and the succession of Tertiary strata, and the second to Santa Cruz by the Southern Pacific Railway for an examination of uplifted marine terraces.

More extensive excursions may be arranged for the week following the meeting.

EDMUND OTIS HOVEY,
Secretary

SCIENTIFIC NOTES AND NEWS

DR ADOLF VON BAEYER, professor of chemistry at Munich, being eighty years of age, has retired from the active duties of his chair.

THE Daly Medal of the American Geographical Society has been awarded to M Paul Vidal de la Blache, professor of geography at the Sorbonne, Paris.

PROFESSOR A BRILL, of the University of Tübingen, and M Planck, of the University of Berlin, have been elected members of the Accademia dei Lincei of Rome

DR J A MURRAY has been appointed acting director of the British Imperial Cancer Research Fund

DR THEOBALD SMITH went last week to Chicago to investigate conditions among cattle that are suffering from foot and mouth disease Dr Smith met members of the faculty at the University of Illinois and made suggestions as to the handling of the situation by state authorities

LEAVE of absence has been given by Royal College of Surgeons London, to the conservator, Professor Arthur Keith, for six weeks, for the purpose of going to America to deliver a course of five lectures on anthropology at the Western Reserve University, Cleveland, Ohio

PROFESSOR FRANCIS E LLOYD, of McGill University, has on account of impaired health been granted leave of absence for the remainder of the present session His address until September will be Carmel, California

PROFESSOR JOHN DUTTON WRIGHT, of the Wright Oral School for the Deaf of New York City, has been elected a director of The American Association to Promote the Teaching of Speech to the Deaf

CAPTAIN H G LYONS, FRS, has been elected president of the Royal Meteorological Society and Mr F Campbell Bayard and Commander W F Caborne secretaries for the ensuing year The new members of the council are Mr J S Dines Mr A P Jenkin and Sir J W Moore

THE officers of the various sections of the New York Academy of Medicine for the year 1915 are as follows Dermatology and syphilis, Dr Charles M Williams, chairman, Dr Walter J Heumann secretary, surgery, Dr Clarence A McWilliams, chairman, Dr John Douglas, secretary, neurology and psychiatry, Dr Israel Strauss, chairman, Dr Foster Ken-

nedy, secretary, pediatrics Dr Walter L Carr, chairman, Dr Royal S Haynes secretary, otology Dr C D Van Wagenen chairman, Dr John A Robinson secretary, ophthalmology, Dr H H Tyson chairman, Dr George H Bell secretary, medicine Dr T Stuart Hart chairman, Dr Nellis B Foster secretary, genito urinary diseases, Dr Leo Buerger chairman, Dr A R Stevens, secretary, orthopedic surgery Dr Arthur H Cilley, chairman Dr P W Roberts secretary, obstetrics and gynecology, Dr LeRoy Broun, chairman Dr George W Kosmak, secretary, laryngology and rhinology, Dr Hubert Arrow smith chairman, Dr Francis W White, secretary

ON the Richard B Westbrook Free Lecture ship of the Wagner Free Institute of Science, four lectures on Invisible Light illustrated with experiments and lantern slides are being given by Professor Robert Williams Wood, of the Johns Hopkins University on Tuesdays, February 9, 16 and 23 and March 2

AT the regular monthly meeting of the Cosmos Club, Washington on February 8 General A W Greeley delivered an address on "The Continent of Antarctica"

PROFESSOR J C BOSE of Calcutta, India, gave two lectures toward the end of January at the University of Illinois the first on "Plant Autographs and their Revelations," the second on "The Curve of Life and Death"

THE annual Samuel D Gross lecture has been delivered at the Jefferson Hospital Philadelphia by J Chalmers Da Costa professor of surgery at the Jefferson Medical College

THE Galton dinner and lecture instituted last year by the Eugenics Education Society in honor of the memory of Sir Francis Galton, will be held this year, as before, on the anniversary of his birth, February 16 Professor J A Thomson will deliver a lecture which will deal with eugenics and the war

WE learn from *Nature* that Professor George Forbes, who has been entrusted by Lady Gill with the duty of preparing a memoir of her late husband, would be glad to be favored with any letters which have been pre-

served by Sir David Gill's numerous correspondents, and would greatly appreciate any notes—narrative, historical, appreciative or anecdotal—relating to Sir David's life and personality. All original letters or other documents will be carefully preserved, and returned to the senders at as early a date as possible. Such communications should be addressed to Professor Forbes at 11 Little College Street, Westminster.

THE death is announced of Dr. Anthony Woodward, at one time assistant in the department of geology and for thirty-seven years librarian of the American Museum of Natural History, New York City.

M. ALFRED TOURNIER, formerly professor of viticulture at the University of California and later connected with the U. S. Department of Agriculture, was killed on December 12 in the war.

VICE ADMIRAL SIR GEORGE NARES, KCB, FRS, the distinguished British navigator, commander of the *Challenger* and of Arctic and other scientific expeditions, died on January 16 at the age of eighty-four years.

MR J. S. HARDING, connected with the British Meteorological Office from its establishment in 1854, until his retirement in 1906, died on January 11, at the age of seventy-five years.

DR OTTO RUSSLIN, professor of zoology in the Technical School at Karlsruhe, has died at the age of sixty-five years.

PROFESSOR J. ROSENTHAL, professor of physiology at Erlangen, has died at the age of seventy-seven years.

DR KARI IILBERMANN, professor of organic chemistry at Berlin, has died at the age of seventy-two years.

DR OTTO SCHEUFR, docent for applied chemistry at Geneva, has been killed while serving in the Austrian army.

AMONG the examinations announced by the New York State civil service commission on February 27 is one for assistant in paleontology in the state museum, at a salary of \$1,200.

Candidates must be graduates of an approved college with some experience in museum work. They should also be able to pass an examination covering the following: The principles and elements of general geology, the principles and elements of stratigraphic geology or stratigraphy, with definite knowledge of the classification of the geological formations, more specially and in some detail those of the Paleozoic system, the principles and elements of general biology, the elements of zoology, specially of the branches herewith named: morphology and classification of animals, embryology, the theories and demonstrations of phylogeny and evolution, the principles and elements of botany with special reference to classification, familiarity with the local flora and the histology of trees.

THE Royal Academy of Medicine of Turin announces that the thirteenth Riberi prize of the value of £800 is offered for the best medical research work presented before December 31, 1916. Particulars may be obtained from Dr. V. Oliva, secretary of the academy.

AN emergency appropriation of \$10,000 was made by the Kansas legislature on February 2 to finance the fight of the state against the foot and mouth disease in four counties under federal quarantine. The action followed a special message from Governor Capper asking the appropriation.

ACCORDING to the London correspondent of the *Journal of the American Medical Association* the scarcity of physicians created by the war is illustrated by the statement of the secretary of the Wolverhampton General Hospital, at a meeting of the committee. He could well remember the time when it was quite a common thing, when they advertised for a house surgeon or physician, to receive from ten to twenty applications for one post. Things gradually became worse, however, until, advertise as they would, they absolutely failed to get any applications for the post vacant. He was sent off to London and visited nine of the leading medical schools, and the result was that after extreme difficulty the resident post was filled. As soon as it was known that medical officers were wanted in the army and navy,

all the resident medical staff volunteered. On two occasions it had been impossible for members of the honorary staff to see all the outpatients. He had gone to London again, and did the round of the medical schools. He could not find a single man who wanted employment as a doctor, and there was not the only hospital in such a position. They had had to fall back on medical women. But though obtainable, they too were scarce. Their resident staff now consists of one man and three women.

MR WM BARCLAY PARSONS has written to the editor of the *New York Times* as follows: "The recent accomplishing of transmitting speech between New York and San Francisco is an event that rightly has attracted public attention. It is an achievement of the very highest importance, and reflects great credit on all concerned. It is, however, a matter of great surprise that in no New York newspaper that I have seen has any mention been made of the man to whom the scientific honor is wholly due. Even the president himself congratulated Mr Bell upon his accomplishment, overlooking the fact that the instruments used to send and receive the first transcontinental message were those used forty years ago showing that whatever advance was indicated by the transmission of speech over 3,400 miles of wire was not due to the instruments at the ends. This great and heretofore never accomplished feat is due entirely to the work of Professor Michael I Pupin, of Columbia University, who, by certain simple devices, has made possible the use of long wires in telephony. Although the devices themselves are simple, their design was reached only after the most pains taking and elaborate mathematical analysis. The final result is intensely practical, but it is based on work of the highest order of pure science."

WITH a view of acquainting the public with the standards, and the results of recent experiments conducted on standardized raw cotton, the division of textiles of the U S National Museum has recently placed on exhibition in the cotton section the nine official grades of white American upland raw cotton;

also a series of samples of the waste cotton obtained from standardized graded cotton, and samples of No 22's warp yarn made from the five standard full grades of raw upland cotton. The principal factors which mark the grade of a cotton are (1) the foreign matter or impurities, such as broken leaves, dirt, sand, strings, motes, naps, gin cut fiber, etc., contained therein, and (2) color. The differences between the several grades can be determined only by the trained eye, but the lowering of the grade due to increasing amounts of foreign matter can be made evident by showing the actual amount of waste material obtained from a definite quantity of cotton. To demonstrate these differences, a certain quantity of graded cotton was carried through the regular operations preparatory to spinning, the amount of waste produced in each operation being carefully preserved, labeled and arranged in exhibition boxes. The series of samples illustrating these experiments, now on exhibition in the National Museum, begins with a box containing four samples, each of the five full grades of Standard Atlantic States Upland Cotton, showing "Good Ordinary," "Low Middling," "Middling," "Good Middling" and "Middling Fair," the last of which is the highest grade. The second series illustrates upland cotton picker waste, and comprises one sample from each of the five full grades of standard upland cotton extracted by the machines employed in opening and preparing raw cotton for the carding machine. The picker waste is thrown out by the four following machines the preparer or opener, the breaker, the intermediate and the finisher. The third series comprises a box containing one sample each of card motes, card fly and card strippings, from the five full grades of standard upland cotton, and shows the matter thrown out as waste in carding raw cotton. The final box includes one sample of yarn spun from gray and bleached raw stock of each of the five grades of standardized eastern and western upland cotton and comprises 20 samples in all. Although the standard grades of cotton were established by the government some time ago, this is the first exhibit show-

ing the waste from the various processes of manufacture through which cotton passes

THE fuel value of two pounds of wood is roughly equivalent to that of one pound of coal. This is given as the result of certain calculations now being made in the forest service laboratory, which show also about how many cords of certain kinds of wood are required to obtain an amount of heat equal to that in a ton of coal. Certain kinds of wood, such as hickory, oak, beech, birch, hard maple, ash, elm, locust, longleaf pine and cherry, have fairly high heat values and only one cord of seasoned wood of these species is required to equal one ton of good coal. It takes a cord and a half of shortleaf pine, hemlock, red gum, Douglas fir, sycamore and soft maple to equal a ton of coal, and two cords of cedar, redwood, poplar, catalpa, Norway pine cypress, basswood, spruce and white pine. Equal weights of dry, non-resinous woods, however, are said to have practically the same heat value regardless of species, and as a consequence it can be stated as a general proposition that the heavier the wood the more heat to the cord. Weight for weight, however, there is very little difference between various species, the average heat for all that have been calculated is 4 600 calories, or heat units, per kilogram. A kilogram of resin will develop 9,400 heat units, or about twice the average for wood. As a consequence, resinous woods have a greater heat value per pound than non-resinous woods and this increased value varies, of course, with the resin content. The available heat value of a cord of wood depends on many different factors. It has a relation not only to the amount of resin it contains but to the amount of moisture present. Furthermore, cords vary as to the amount of solid wood they contain, even when they are of the standard dimension and occupy 128 cubic feet of space. A certain proportion of this space is made up of air spaces between the sticks, and this air space may be considerable in a cord made of twisted, crooked and knotty sticks. Out of the 128 cubic feet, a fair average of solid wood is about 80 cubic feet. It is pointed out, however, that heat

value is not the only test of usefulness in fuel wood and since 95 per cent of all wood used for fuel is consumed for domestic purposes, largely in farm houses, such factors as rapidity of burning and ease of lighting are important. Each section of the country has its favored woods and these are said to be, in general, the right ones to use. Hickory, of the non-resinous woods, has the highest fuel value per unit volume of wood and has other advantages. It burns evenly, and as housewives say, holds the heat. The oaks come next, followed by beech, birch and maple. Pine has a relatively low heat value per unit volume, but has other advantages. It ignites readily and gives out a quick hot flame but one that soon dies down. This makes it a favorite with rural housekeepers as a summer wood, because it is particularly adapted for hot days in the kitchen. The fuel qualities of chestnut adapt it particularly to work in brass foundries, where it gives just the required amount of heat and it is therefore in favor. Coastwise vessels in Florida pay twice as much for Florida buttonwood as for any other, because it burns with an even heat and with a minimum amount of smoke and ash. The principal disadvantage of the resinous pines is their oily black smoke.

THE museum of the California Academy of Sciences has received as a gift the large collection of marine, freshwater and land shells assembled by the late Henry Hemphill. The generous donor is Mrs Charlotte Hosmer of Oakland, California, the daughter of Mr Hemphill. The collection contains between 60,000 and 70 000 specimens, representing 12,000 to 15,000 species and is particularly rich in west coast species. The museum of the academy has also recently acquired the entire Lowe collection of Indian baskets, pottery, stone implements Navaho and Chilkat blankets, and miscellaneous objects of Indian manufacture and use. This collection comprises more than 1,500 Indian baskets, and several hundred pieces of pottery and miscellaneous objects. The collection of baskets, which is said to be one of the most complete and valuable in existence relating to the

Pacific coast tribes, is the result of many years devoted to the subject by the late Professor and Mrs T S C Lowe, of Pasadena. The collection comes to the academy as an indefinite loan through the generosity of Hon Wm M Fitzhugh of San Francisco. Mr Fitzhugh not only gives the collection but will also meet all the expenses of labeling card cataloguing, providing cases of the best type and installing the collection in the academy's new museum building now under construction in Golden Gate Park.

By an amendment to the by laws recently adopted by the Academy of Natural Sciences of Philadelphia, the members can now borrow certain books to be designated by the librarian and the library committee. The library has been exclusively for reference, no one having been allowed to take books from the building since 1859.

THERE has been a decline of more than 6 000 applications for patents during 1914 in Great Britain. Whereas in 1913 the number of patents applied for was over 31,000—practically the same as the preceding year—the total of 1914 amounts to barely 25 000. The causes of this falling off are said to be the interference with certain trades consequent upon the war and the cessation of applications from hostile countries. As these causes apply to only the last five months of the year, the decrease during that period amounts to about one half.

A SERIES of six popular demonstrations in science has been arranged by Syracuse University and the Technology Club of Syracuse, as follows:

January 14—The production and application of electricity. Dean William P Graham, of Smith College of Applied Science.

January 21—Some of our common birds and how they are helpful or harmful. Dr Chas. C Adams, forest zoologist of the New York State College of Forestry.

January 28—Bacteria, friends and foes. Professor H N Jones, of the department of bacteriology, Syracuse University.

February 4—Gas engines—their construction and operation. Mr George Babcock, expert with the Franklin Automobile Co.

February 11—How timber decays and how this decay may be prevented. Dean Hugh P Baker, of the New York State College of Forestry.

February 18—Illuminating and other gases and how they are produced and used in our industries. Dr E N Patten and Professor C R Hoover of the department of chemistry of Syracuse University.

UNIVERSITY AND EDUCATIONAL NEWS

MR GEORGE SKELTON YUILL of London and Australia, has given a sum of \$20,000 to the University of Aberdeen to found a scholarship in chemistry in the memory of the arts class of 1864-68 of which he was a member. The scholarship will be held by a student of the university for the purpose of research within it, or for the study of the practical applications of chemistry elsewhere. Mr James Campbell LL.D., chairman of the governors of the North of Scotland College of Agriculture, has founded four bursaries or scholarships to be held by students of the university in the college.

It is stated that there are this year matriculated in the University of Berlin 7 037 men and 898 women, as compared with 8 200 men and 850 women last winter.

DR WILLIAM H PARK has offered his resignation as dean of the New York University Medical College because of the ruling of the department of health that its department heads shall not hold administrative positions elsewhere. Dr Park is director of laboratories. He will retain his position as professor of bacteriology and hygiene in the college.

PROFESSOR DE LA VALIÈRE POUSSIN, of the University of Louvain will, as has already been announced, give a course of lectures at Harvard University. The lectures which will be in French are on Lebesgue Integrals. The first lecture will be given on February 16 and the course will be given twice (possible three times) a week throughout the remainder of the academic year. There will also be supplementary lectures and explanations in English by Dr Dunham Jackson.

PROFESSOR R. M. BARTON, of the University of New Mexico, has been appointed professor of mathematics in Lombard College.

DISCUSSION AND CORRESPONDENCE

THE RATE OF CONTINENTAL DENUDATION¹

IN an article bearing the above title, published in *SCIENCE* December 25, 1914, Charles Keyes contends that determinations of mineral matter carried by such streams as the Mississippi are of little or no value, particularly as a basis for estimates of "the rate of lowering of the continental surface through stream corrosion" (and transportation?). To the present writer it seems that the article as a whole and most of the individual statements in it are likely to give many readers a wrong impression, and that some of the statements, for example that "The elaborate stream measurements thus go for naught" are altogether and demonstrably untrue.

The great practical value of the water analyses is too obvious to need elucidation. They are essential in water supply problems almost innumerable, especially in connection with providing water for industrial and municipal use, and for irrigation, in fact they were made primarily for use in solving just such problems, not "with the express purpose of determining the rate of lowering" of the land surface. The measurements of stream discharge that have been utilized in calculating the rates of denudation furnish the basic data for many of the greatest public and private hydraulic developments in the United States.

The educational value of the data afforded by these determinations is equally obvious. That the Mississippi is gathering from the surface, mostly from the soil, of its own basin several hundred million tons of earthy material every year and is dumping this material into the Gulf of Mexico, that practically none of this material is being returned, that some parts of the basin are losing by stream action more rapidly than others, that the earth's surface everywhere is being continually modified by such action—valleys carved, hills razed, and

so on—these are not facts that it is worthless to ascertain.

Apparently Mr. Keyes wishes to convince his readers that the stream observations that he assails are futile because the effects of stream action are modified by internal earth movements and by the introduction of wind-blown materials.

That parts of the Mississippi basin have been uplifted in past geologic time is a matter of common knowledge, but the writer does not see that it affects the precision of conclusions regarding the amount of material now being removed by the streams. The statement that "Since Glacial times—perhaps 10,000 years ago—a very considerable part of the upper Mississippi Valley appears to have been elevated not less than 500 or 600 feet" must have reference to the remarkable work of late years on raised Pleistocene beaches of the Great Lakes, but the published reports on this work indicate that only a small part of the Mississippi Valley has been affected by the uplift, and none of it so much as 500 or 600 feet. The 500 and 600 foot isobases lie entirely outside of the Mississippi basin in the vicinities of Lake Superior and Quebec.

As to wind deposits, it should be remembered that strata of other than wind origin lie at or near the surface throughout the Mississippi basin, whereas if dust had been accumulating "over the entire Mississippi Valley faster than the river and its tributaries are carrying rock waste to the sea," water-laid and ice-laid materials would not outcrop but would be deeply buried under eolian dust instead of under products of their own decomposition. That large quantities of material have been and are being shifted by the wind no one doubts. The literature on the subject is voluminous, as is shown by the excellent bibliography compiled by Stuntz and Free, and many precise data have been recorded. For example, J. A. Udden calculated in 1894 that the capacity of the atmosphere over the Mississippi basin to transport dust may be a thousand times that of the river, but he did not fail to observe that the actual load carried by the air is "an insignificant fraction" of its capacity load. Dust, however, is shifted back

¹ Published by permission of the Director, U. S. Geological Survey.

and forth in the basin by the wind, whereas stream sediment and dissolved matter travel in one direction only. It is well known that in drawing conclusions regarding the rate of denudation account should be taken of the material transported by wind. Attention was called to this factor of the problem by E. E. Free in an article published in *SCIENCE*, March 12, 1909, but it is difficult to comprehend how conclusions as to the "rate of lowering of the continental surface through stream corrosion" are affected by aerial transportation (Erosion rather than corrosion is probably here meant, for corrosion does not include transportation).

In the fourth paragraph of his article Mr. Keyes speaks of wind-blown dust and then says:

In recent geologic times also, the western half of the basin has actually had deposits laid down upon its surface to a thickness of not less than 1000 feet.

Now if "recent geologic times" means most of the Tertiary and Quaternary periods (of which *Recent* time is but a small part), if the "western half of the basin" means a part of the western half of the basin, and if "deposits" means not only wind deposits (loess and sand) but also and predominantly aqueous deposits, the statement would appear to be in accord with the facts. Nevertheless it might still be characterized as trite and irrelevant, for the existence of Tertiary and Quaternary strata in the western part of the basin is well known and the commonly accepted conclusion that the great western tributary, Missouri River, carries 150 to 200 million tons of mineral matter out of its drainage basin every year is on just as firm a basis as before.

EUGENE WESLEY SHAW

ALBINISM IN THE ENGLISH SPARROW

TO THE EDITOR OF *SCIENCE*. The note in *SCIENCE* of January 1, concerning albinism in the English sparrow recalls several observations made by the present writer at various times. Semi-albinism, or spotting, or mottling with white in the plumage of these birds is not at all rare, though of course not particularly conspicuous unless one is especially

used to the study of birds in the open. I have seen this feature among these sparrows both in this country and in Europe at several times and places. But complete albinism is less common, though not so rare as the note referred to above might imply. A number of years ago in Oxford, Ohio, I found in a brood of sparrows just in flight from the nest three specimens which were perfectly white and with the characteristic pink eyes of the pure albino. Two of these birds I was able to capture, the other escaped. Two of the same brood were quite normal in plumage. Neither of the parent birds was an albino, and so far as one could know the phenomenon was quite spontaneous in this brood. Another case which came to my knowledge quite recently was in Syracuse. In this case a single specimen was observed by school children of one of the grammar schools of the city who at once ran to the teacher with the news, and the teacher having seen it communicated with me as to the significance of a feature quite new to her. While I did not see this specimen myself, the validity of the case is beyond doubt and may be accepted as another example of the phenomenon.

In this connection it may be well to call attention to several cases of partial albinism which I have noted in the common robin. Several years ago I found such a female robin brooding a nest near my house and I took pains to watch the outcome. None of the young gave any indication of white plumage. Another case has come under observation in a park adjoining my present home in Syracuse. Here again, the robin was a female, and had a conspicuous patch of white feathers on the back and shoulder. The specimen has been noted now for three successive summers, and though careful attention has been directed to the young no evidence of similar markings has been noted. Albinism being a recessive character tends to disappear under ordinary conditions of mating, hence its comparative rarity in a state of nature.

SCIENTIFIC BOOKS

Leçons sur les Fonctions de Lignes Professées à la Sorbonne en 1912, par VITO VOLTERRA, recueillies et rédigées par JOSEPH PÉREZ Paris, Gauthier Villars, 1918

The point of view of this book of Volterra's is the systematic generalization of systems of relations of simple type by means of a passage from finite to infinite. We are already familiar with this procedure, in the subject of integral equations first in the work of Volterra himself, suggested then in the work of Fredholm, and minutely worked out in the papers of Hilbert, his associates and students. But whereas perhaps Hilbert has limited himself to a few aspects of the question and rigorously justified the passage from finite to infinite, considering the subject of forms in an infinite number of variables as a subject for investigation in itself, Volterra has made wide application of an heuristic device for the purpose of obtaining results which can then sometimes more simply be justified by methods proper to the new subjects themselves. This device is as old as the idea of infinitesimals.

After mentioning the familiar generalizations of this kind, of sum and product, Volterra considers briefly the subject of the generalization of the multiplication of substitutions coordinate with the integration of linear differential equations, and then devotes the pages of the book proper to the generalization of the idea of function of several variables. This generalization involves the general principles of the study of functional relations.

We are concerned then, in the limit, with the investigation of functions which depend on an infinite number of variables—in particular, on all the points of a curve or on all the values of another function throughout a certain interval. The general method of making such a study is by procedure from the finite to the infinite.

As an illustration of such a procedure, Volterra cites, in the Introduction, a treatment of the restricted problem of three bodies, by the application of Cauchy's method. The motion of the small body, the only one not known, can be determined by summing the motions obtained by considering the larger

bodies as temporarily fixed at various points of their orbits, and proceeding to the limit as these various points on each orbit are taken closer and closer together.

Another passage of the Introduction relates to the definition of the derivative of a function of a curve and is worth while quoting, since in this case the example is proper to our subject itself. "If a quantity depends upon a curve, we can study the effect produced on the quantity by a variation of the curve. If this variation is very small and limited to the neighborhood of a point of the curve we arrive at the notion of derivative.¹ For each point of the curve we shall in this way have a derivative. By superposing such variations of the curve, made in all its points we find the differential, or variation, of the quantity, which will be expressed by means of an integral, in fact, since a function of a curve is a function of an infinite number of variables, the sum which expresses the differential of a function of several variables leads, by the passage to the infinite, to an integral.

"We can then take up the study of differentials of higher order, and thus come to an analytic development analogous to the Taylor's series. The simple double and triple sums, etc., which occur in the development of a function of several variables, are replaced by simple, double, triple, etc., integrals."

The character of this analysis is thus shown. Its purpose is to investigate the phenomena of hysteresis and "evolution" or "heredity" in physical systems—occurrences where the state of the system is supposed to depend upon the history of the system, s , e , to depend upon the values of certain functions throughout all previous instants of time.

In regard to hysteresis and evolution, in physics as in biology, we may adopt two different points of view. One possible standpoint is that the future state of a system is determined entirely by its state at a given instant, and if the history of a system is used in determining its subsequent behavior, that

¹ As the limit, under proper restrictions, of the ratio of the variation of the function to the integral of the variation of the curve, in that neighborhood.

is merely a sign that the instantaneous conditions are insufficiently known. The other point of view is that the history can not be replaced by the consideration of contemporaneous elements, in other words that a finite number of present elements can not replace the infinity past instants in the determination of the state of the system. The question as to the presence of heredity effects in physical phenomena is, as Volterra points out, of the same character as the old Newtonian question of action at a distance. In fact, if we take account of the theory of relativity and the four dimensional space time space, the two questions meet.

Such questions are important if we try to reduce our system of the world to one that is entirely kinetic. In that case we must get rid of the "coefficients of heredity" by explaining them in terms of concealed motions. It may, however be impossible completely to reduce physical phenomena to a finite number of elements no matter how described in terms of functions and variables, without exceeding the time limit for speech, and one method may not be more "fundamental" than another. But regardless of our attitude towards the two aspects of the question, or our opinion of the practical value of making such distinctions on the ground of "reality" or "truth" we can not in any case deny the value of the analysis that enables us to take account of such a thing as the history of the system.

Let us turn now to two subjects, elasticity and electricity, where this analysis seems to be usefully introduced. In the usual treatment of elasticity, we have Hooke's law, connecting the deformations and tensions of the system, in electricity the induction and displacement are also connected by linear relations. If now we assume that the tension at any time depends linearly not only on the deformation at that time, but also on the deformation at all previous times, we can introduce this fact into our equations by adding, in our expression of Hooke's law, a term in the form of an integral, whose integrand represents the contribution to the tension at a time t , due to a deformation acting at a time

τ through an interval of time $d\tau$. In this way Hooke's law becomes an integral equation, or a system of integral equations and the differential equations that determine the deformations or the tensions become integro differential equations. In a similar way, integro differential equations are introduced into the subject of electricity.

The study of the methods of integro differential equations, their solutions, and their applications to the subject of hysteresis or heredity, form the subject matter of the book from Chapter V on. In connection with the relative importance which the theory of this subject has assumed in the presentation of Professor Volterra we may remember that in the case of elasticity it seems to have received important experimental verification in the work of our American physicists Professor Webster and Dr Porter.

A detailed analysis of the contents of the book is unnecessary. Some points however, should be given special mention, because of their universal interest. Chapter IV is devoted to functional equations in general, that is to implicit functions of curves. Theorems are obtained which correspond, first to the inversion of an analytic function, and second to the more extensive theorem on the determination of implicit functions in general. In fact it may be noticed that the theorem might be given in such a form as to include the ordinary theorem on implicit functions as a special case, although with respect to the scope of the book such a generalization would be trivial. The condition for the "closed cycle" (Chapter VII) deserves special attention because of its relation to the problem of heredity which as we have seen, is a central one for the book. In this chapter, section 10 is a first essay at a possible treatment of magnetic hysteresis. Another interesting subject is the application of permutable functions to the solution of integro differential equations. It is in connection with this subject that are introduced various new sorts of transcendental functions, similar in a way to the exponential function, the sine, and so on. The quality of periodicity, which appears to be lacking,

might be materialized by means of a slightly different sort of symbolism

The book does not attempt to give a completely exhaustive account of the subject of functions of curves. It omits notable researches by Hadamard, Levy, Fréchet, and confines itself rather closely to the personal researches of the author who is of course the inventor of their analysis and the principal source of its development. But if it lacks consideration of some of the possible branches, it makes up for the omission by possessing the artistic quality which is characteristic of unified original work. Moreover, the reader will continually find references to theoretical physics and other branches of mathematics, which, besides illuminating profoundly the matter in hand, testify to a not common comprehensiveness of thought on the part of the author.

G C EVANS

The Essence of Astronomy By EDWARD W PRICE G P Putnam's Sons 1914 Pp xiv + 207 Illustrated

The Century Dictionary defines *essence* as being the inward nature, true substance, or constitution of anything. From the title of Mr Price's book, therefore, one would expect to find something of the inward nature of the solar system, or true substance of the stellar universe, some hint as to the underlying causes and formations of the heavens. But one who opens the book with such expectations will be most grievously disappointed, for the work is but a compilation of the simplest statistical facts, facts which have been compiled and written about over and over again. Further, the book contains some strange and new conceptions to classify the milky way as a freak, and double and variable stars as oddities, is certainly new, and such classification, itself, might even be called odd and freakish.

The book is well made mechanically, well printed, with clear and beautiful illustrations, but otherwise it is one of dozens of similar crude compilations.

CHAS LANE POOR

An Introduction to General Psychology By ROBERT MORRIS OGDEN Longmans, Green and Co, 1914 Pp xviii + 270

Professor Ogden's text book is the outcome of a definite abandonment of the purely sensationalistic conception of psychology. Dr Ogden defines his science as "the study of mental happenings." He treats not merely of "mental contents" and their physical conditions, but also of the "mental activities" which constitute what he rather vaguely calls the "purposive aspect" of mental happenings. As elements of mental contents Dr Ogden enumerates sensations, images, thoughts—which he classifies as notions or relations—and affections. Attention, memory, perception, ideation, emotion and reaction are brought together under the heading "The Synthetic Facts of Mind." The concluding section of the book contains chapters on "mind and body," "personality" and "character." In the last of these chapters Mr Ogden suggests the relation of psychology to logic to esthetics, to ethics and to religion. Under the second heading he discusses mainly sleep, dreams, hypnosis, multiple personality and insanity. Not all teachers—it may be noted—will approve the inclusion of the topics just named in a book of fewer than 300 pages, and many will regret the brevity with which all topics are treated and the omission of "all diagrams, references to literature and practical demonstrations."

The writer of this notice is glad to find Professor Ogden in substantial agreement with Herbert Spencer, William James, Binet, Meinong, the Würzburg school, and with several recent American writers in his view that thought elements as well as sensational and affective elements should be explicitly acknowledged in a text book of psychology, and she welcomes also his repeated descriptions of consciousness—the relating consciousness (pp 14 ff), affection (pp 85 ff) and will (pp 171 f)—in terms of the self who is conscious. Occasional artificial constructions and a certain vagueness in the use of the term "mental activity" might indeed have been avoided, had this natural and inevitable point of view been more steadily held.

The book and in particular chapters I II, VIII XII and XIII may be commended to those who are interested in the development of psychological theory. Almost every page is marked by the touch of the clear thinker the first hand observer and the careful experimenter.

WELLESLEY COLLEGE

PETROLEUM DEVELOPMENTS IN FOREIGN COUNTRIES

THE worldwide activity in the search for petroleum deposits of commercial importance which characterized the year 1913 continued unabated during the early part of 1914. During the later part of the year development in proved areas was greatly curtailed and exploration work postponed on account of the European war and the enormous overproduction of oil in the United States and Mexico.

John D. Northrop of the United States Geological Survey is authority for the following statement discussing the petroleum developments in foreign countries in 1914 which has just been made public by the survey:

NORTH AMERICA

Canada—The productive fields of Ontario and New Brunswick continued to furnish the declining petroleum output of the Dominion. Though considerable effort was made to extend the boundaries of the productive areas new production sufficient to offset the decline in older wells was obtained only in the Belle River field Ontario. Good gas wells continue to be found in the Tilbury district Ontario, but attempts to retard the declining oil output were unsuccessful.

Wildcat activity with apparently undue interest centered in the vicinity of Calgary Alberta was the feature of the year in the western provinces. The discovery of small quantities of high grade petroleum at depths of 1562 and 2700 feet in the Dingman well, southwest of Calgary created a hysterical rush for mining locations in the area. Drilling was commenced at a number of points southwest and northwest of Calgary and though proving

the presence of small quantities of heavy oil in certain areas of favorable structure failed to demonstrate the true extent or value of the field before the end of the year. In northern Alberta the lack of transportation facilities retarded the development of the promising oil strikes of the Athabasca Oils Ltd. near Fort McKay.

In British Columbia encouraging oil indications in the valley of Flathead River and in the vicinity of Revelstoke Kootenai County and at Pitt Meadows New Westminster County near Vancouver resulted in more or less prospect drilling.

In Saskatchewan interest was centered at Moose Jaw where good oil showings were found but included additional projects at Regina Battleford and Saskatoon and in Souris Valley where oil seepages occur near Roche Perce.

Mexico—Early in 1914 field operations in the oil districts of Mexico were very active—more so in the northern fields at Panuco and Topila than in the southern fields where the work was interrupted by the belligerent political factions. The bringing in of an enormous gusher by the Corona Oil Co. (Dutch Shell) at Panuco on January 11 became the signal for a pronounced increase of work in the northern fields where as in the southern fields the lack of adequate storage facilities tended to hamper developments greatly. Work in all districts was abruptly curtailed and in many places terminated by the exodus of operators and workmen beginning in April. Although the subsequent activities of the warring factions resulted in no great damage to the petroleum interests the resulting conditions of unstable government prevented the resumption of more than nominal activity in the oil fields up to the end of the year. Late in the year the resumption of local oil consumption by the Mexican railroads and mining industries served to revive activity to some extent at Panuco and Topila.

Of more than passing interest was the fire which raged about the famous Potrero del Llano No. 4 well of the Mexican Eagle Oil Co., during the later part of the year. Seepages of

oil escaping to the surface after the well had been capped were ignited by lightning on August 14, and up to the close of the year the fire, though confined to a small area, had defied all efforts to extinguish it.

During the year the Panuco field was extended to the southwest and the Topila field to the west. Wildcatting at Rancho El Chapopote revealed promising indications of an oil field near Campeche. State of Campeche. A four still topping plant was installed by the Standard Oil Co. at Tampico, and construction work was started by the Tampico & Panuco Valley Tramways Co. on a 25 mile railroad connecting Tampico with the Panuco oil field.

CENTRAL AMERICA AND WEST INDIES

Examination of the petroleum indications in Honduras resulted in the formation of the Honduras Oil Co., financed by Honduras capital which is reported to have obtained concessions in the departments of Atlantida Yoro and Comayagua.

By legislative decree the government of San Salvador has granted to Alfredo Leon Schlesinger, a native of Austria Hungary, the exclusive privilege of conducting geologic studies of the mineral resources of San Salvador for one year and of exploiting them for a period of 30 years, subject to a 25 per cent royalty and to the reversion of all property to the government at the end of the concession period.

Drilling for oil in Cuba continued in the vicinity of Cardenas.

The testing of promising structure and oil indications in Barbados was retarded by the failure of the legislature to enact laws providing for such exploration.

Developments at Trinidad resulted in a marked increase in production over previous years, despite the deterring effects of meager storage facilities, which, together with the influence of the European war, served to greatly curtail operations toward the end of the year.

SOUTH AMERICA

Colombia—The discovery of petroleum and natural gas at Tubara, near the important

Caribbean seaport of Barranquilla, indicates the development of an important oil field in close proximity to the Panama Canal.

Ecuador—Investigations of the petroleum indications along the coast and in the mountains near Quito by a Dutch syndicate, suggest the possible development of Ecuador's petroleum resources in the near future.

Peru—Developments in the proved oil fields of Peru were without notable incident. The production showed a moderate increase during the early part of the year necessitating the erection of additional tankage at Zorritos.

Bolivia—Geologic investigations in the area between the Incabusi and Aguaraygua ranges have shown the presence of a considerable area of prospective oil land south of Sucre and the reported acquisition of petroleum concessions in that region indicates that the area will be thoroughly tested.

Chile—Several companies were organized in Santiago to test certain districts in which surface indications of petroleum have been known for many years.

Argentina—In the Comodoro Rivadavia oil district, in southern Argentina, 5 000 hectares (12 355 acres) of land has been reserved by the government, of which 350 hectares (865 acres) is being exploited by the state. Legislation providing for the exploitation of the petroleum deposits in Comodoro Rivadavia is now under consideration by the Argentine Congress.

Venezuela—Work was continued by the Caribbean Petroleum Co., on the east coast of Lake Maracaibo in the shallow sand field opened late in 1913.

EURASIA

Russia—On the Apsheron Peninsula the oil fields in the vicinity of Baku showed a steady decline, development being retarded by a strike of the oil field workmen which lasted from June 11 to July 31. In spite of the effects of the strike and the immediately succeeding mobilization of the Russian army, which involved a great number of oil-field workers, the production of the Baku fields made sub-

stantial headway during the later part of the year

At Grosny in northeastern Caucasus extensions of productive area yielded a gratifying increase in production. At Maikop production decreased in spite of significant oil strikes in the Khadijenskaja district north west of the developed portion of the field.

In the relatively new Ural Fmba or Ural Caspian area the Dos Sor field attracted the greatest attention but minor activity was evident in some forty other fields scattered over an area of 300 square miles east of the mouth of Ural River. A refinery at Bolshaja Rakusha near Gurniev commenced operations in January. On the east side of the Caspian Sea in the Ferghana Valley Turkestan developments in the new Sol Rokh field resulted early in the year in a production which surpassed that of the old Tchumion district. Turkestan Developments in Teheleken Island were nominal.

Roumania—Despite the increasingly active drilling campaign which characterized Roumanian developments in the early part of the year and resulted in notable western and southwestern extensions in the Bana Moreni district and in the discovery of deeper lying productive strata in the same area the net production of the country registered a decline. This decline which was not in any sense due to the exhaustion of the productive fields resulted in part from interruptions incident to the mobilization of the Roumanian army but chiefly from the conditions of overproduction arising from restricted markets and low prices consequent on the European war which involved the countries that bound Roumania on all sides. Notwithstanding these retarding influences the later part of the year recorded slight increases of productive areas in the Baicoi Febatori and Razvadlaid districts.

Austria Hungary—In the Galicia fields active development early in the year resulted in establishing a southern extension of the Boryslaw field which clearly indicates the ultimate connection of that field with the development at Mraznica. Operations in the oil fields during the later part of the year were much curtailed as the adjacent territory be-

came the theater of conflict between Russian and Austrian troops.

In Hungary the discovery of oil was reported in the village of Morvaor district of Szemice Nyitra county.

Spain—Promising surface indications of petroleum in the area about Cadiz in southern Spain were examined at the expense of the Spanish government. In northern Spain near Santander petroleum in small quantities was discovered in a boring made for salt.

Turkey—Plans for the active development of the imperfectly operated oil fields in the Tigris and Euphrates valleys in the vicinity of Mosul and Bagdad were postponed by the European war.

In Palestine prospecting was active at Makarim in the area between the River Jordan and Deraa adjacent to the Hedjaz Railway by the Turkish Petroleum Co. a successor in interest to the Syrian Exploration Co.

Persia—Interest in Persian developments was greatly stimulated by the decision of the British government announced May 22 to acquire a majority interest in the Anglo Persian Oil Co. and thereby secure for the almsholy undisputed access to valuable oil lands adjacent to the Persian Gulf. The effect of the European war on this agreement was not apparent at the end of the year.

India—Operations in the Yenangyaung Singu and Yenangat districts in Burma were nominal the search for deeper sands in the first two districts furnishing variable results not altogether satisfactory. Wildcatting in Burma resulted in the opening of a promising new field at Indaw Kindat Township in the upper Chindwin district.

China—Under the terms of an agreement entered into by the Chinese government and the Standard Oil Co. of New York a joint investigation of the petroleum resources in and near Autin fu Shensi Chengte and Chihli was undertaken.

Japan—Interest was centered in the Akita oil district on the west coast of Nippon near the north end of the island where on May 25 and September 1 gushers credited with flows of several thousand barrels daily were brought in by the Nippon Oil Co. In 14 other known oil

bearing localities in Japan no developments of note were reported

OCEANIA

In Borneo, Sumatra and Java no notable additions to productive area were made. In the northeastern portion of New Guinea (Papua) petroleum deposits were reported near Entape, and in the southeastern portion of the island oil indications of great promise were found by Australian geologists on the western flank of the Albert Mountains between the River Purari on the north and Yule Island on the south.

New Zealand—Interest was centered in the Taranaki district. New Plymouth, North Island where late in the year four wells producing oil simultaneously were believed to indicate the presence of a considerable quantity of oil in the locality. On South Island the Shell interests abandoned a test well at 900 feet on account of the presence of metamorphic slate.

AFRICA

Algeria—Work on the test well of the Algerian oil fields at Abder Rahm was suspended in April 1914 at a reported depth of 902 meters on account of parted casing. A second test started in March was located at Messila.

Egypt—The activity of the Anglo Egyptian Oilfields Ltd. resulted in the completion of a number of creditable wells during the year in the Gernah and Hurgada fields.

Somaland—Promising oil indications were found in British Somaliland on the south side of the Gulf of Aden.

A STUDY OF THE INFLUENCE OF VOLCANIC DUST VEILS ON CLIMATIC VARIATIONS

The series of overlapping yearly means of temperature, expressed graphically, show most characteristic crests and depressions. In the case of tropical stations, in particular, the crests of the curves are very regular and recur at intervals of two to three years, practically at the same time all around the world.

As a general result of a detailed study of

the temperature data of the years 1900-1909, for Europe, Greenland and North America, I have found some striking correlations between these equatorial variations and the more complicated variations of temperate and arctic regions. This research has been published recently in the *Annals of the New York Academy*.

In another study of all available temperature data of the years 1891-1900, published some years ago I have shown that terrestrial atmosphere at the earth's surface, has been warmer in 1900 than in 1893 by at least 0.5°C . On the maps representing the geographical distribution of the departures of annual means from the quasi-normal values of ten yearly means the areas of positive departures have been called thermopleions and the areas covered by negative departures antipleions. On the curves of overlapping means the crests correspond to pleions and the depressions correspond to antipleions. I have presumed that the excess of pleions over antipleions corresponding to pleionian crests of equatorial stations may be due to an increase of the solar constant.

Recently many papers have been published about the influence of volcanic dust on meteorological phenomena on atmospheric temperature in particular and it has been admitted by different authors that volcanic dust must have been a factor in the production of past climatic changes.

The hypothesis ascribing the origin of climatic variations to the presence of volcanic dust veils in the higher atmospheric layers, is a very plausible argument against my supposition that the changes in terrestrial temperature are due to cosmical causes. Before going any further in my researches on the mode of formation and the dynamics of pleionian variations, it was therefore necessary to find out to what extent one may be justified to suppose that the antipleionian depressions of temperature are simply caused by the presence of volcanic dust veils.

In a paper read before the New York Academy of Sciences on December 7, I have studied

more in detail the effect of the eruptions of 1883, 1902 and 1912 on atmospheric temperature. Only volcanic eruptions of an explosive character had to be taken into special consideration, because it is only when volcanic dust has been projected in great quantity above the ordinary elevation of the cirrus clouds, that this dust could remain in suspension long enough to be spread out all around the globe by the winds of the stratosphere.

In the case of the famous Krakatoa eruption in 1883 the optical phenomena produced by the volcanic dust veil have been observed practically all over the world. The explosion occurred on August 27, 1883. The main sky phenomenon produced by the dust, went around the world in fifteen days from E to W along the equator spread out N and S was observed in the Gulf of Mexico by the end of September and all over the United States in November. Curiously enough the effect of the Krakatoa dust veil on atmospheric temperature seems to have attracted no special attention.

Besides the Krakatoa, other volcanoes have been very active during the year 1883. St. Augustin and Bogoslof of the Aleutian chain of islands, as well as the Ometepe, may be cited.

The study of the temperature data of the year 1902 is also of special interest not only because during that year the world's volcanic activity was greatly intensified, but also because some of the explosive eruptions which occurred undoubtedly produced a dust veil in the higher layers of the atmosphere.

Already in 1901 the outbursts of Mt. Colima, Mexico, were more frequent and more intense than during the preceding years. The same in 1902 and even more so in 1903.

On May 7, 1902, La Soufrière, St. Vincent, was in violent eruption. The particular feature of this eruption was the enormous amount of dust which was thrown into the air and distributed over a vast, somewhat elliptical area.

On May 8, 1902, a sea of fire destroyed St. Pierre, Martinique. The following violent

eruptions of Mt. Pelée occurred on May 20 and 26, June 6, July 9 and August 30.

The influence these eruptions may have had on the thermal transparency of the higher atmospheric layers is questionable. The excellent photographs taken by Lacroix show, indeed, that the occasional blasts of incandescent gases and ashes did not exceed an altitude of 4,000 m. Only an extremely small proportion of the projected pulverized ashes could have reached the average altitude of the cirrus clouds or even the stratosphere. This may not have been the case in the violent eruptions of the Santa Maria volcano, in Guatemala. The eruptions began on October 24, 1902.

The eruption of the Maui, on Savaii of the Samoa Islands which occurred October 30, 1902, was not violent enough to be taken into consideration. The same may be said about the Isalco eruption in Salvador. On the contrary, the Torishima eruption of August 7 and 9, 1902 seems to have been very violent.

There can be no doubt that during the year 1902 a considerable quantity of pulverized lava must have been projected into the higher layers of the atmosphere, above the clouds. Bishop's ring was observed anew as well as extraordinary twilight phenomena, but a comparison is hardly possible with those which were due to the Krakatoa eruption. One single volcanic explosion, if sufficiently violent, may therefore obscure the stratosphere very much more than a score of violent eruptions of a less explosive character.

This seems to have been the case of the Katmai eruption. Katmai volcano is in the Aleutian range, Alaska, latitude 58° N, longitude 155° W, approximately. On the afternoon of June 6, 1912 it suddenly became explosively eruptive, continued in a state of great activity for about three days, and was reported to be still somewhat active at the end of October, 1912.

The fact that the Katmai eruption occurred in a far northern latitude, and has not been followed by similar volcanic outbreaks in other parts of the world, is a most valuable

fact. Because since the general atmospheric circulation of the southern hemisphere is independent of that of the northern hemisphere it is difficult to imagine how the haze produced by the Katmai eruption could have been carried south of the equator.

The meteorological observations made on the summit of Pikes Peak extend from 1874 to 1887. It seemed to me that the records of this station—situated near the center of the North American continent on an altitude of 14,111 feet—may be considered most reliable material for the study of the influence of the dust veil of the years 1883 and 1884 upon temperature conditions in the United States.

In this abstract it is impossible to enter into the details of the discussion. I will therefore simply mention the fact that the curve of the overlapping annual means observed on Pikes Peak compared with other curves and the Port Darwin curve in particular forces us to admit that the formation of a pleion in the states has been completely counteracted by the influence of the dust veil. The mean of September 1883 to August 1884 must have been affected the most and this maximum effect of the dust veil must have produced a lowering of the annual mean temperature of about 3.4°F .

The curve of the consecutive means of the temperatures observed at the Batavia Observatory confirms this result and so do the curves of Singapore, Port Blair, Colombo, Bombay and Aden.

The curves of Bombay and Port Blair as well as the Port Darwin curve show distinctly the antipleonian depressions preceding and following the abraded pleionian crest.

During the terrific eruptions of Mt. Pelée on May 8 and 20, 1902, the usual meteorological observations have been made at Fort de France. The mean temperatures were affected but very slightly. The pleionian crest of 1902-03 as indicated on the curve of consecutive means has been depressed a little but certainly not more than 0.15°C or 0.2°F . It is difficult to judge how much the mean temperatures of the individual months have been affected.

The departures of the months of May 1903 to the end of 1903 are all above the average and if the slight deflections observed during the period of great volcanic eruptions must really be attributed to dust veils it may be presumed that the means of some months have been affected more than those of other months but none sufficiently to mask the pleionian character of the departures. Moreover the effect of the dust veil ceased long before the complete development of the antipleonian depression of 1904-05. This antipleon can therefore not be considered as a consequence of the formation of the volcanic dust veil.

The curves of the consecutive means of temperature for Pará, Cayenne and the West Indian stations Port au Prince, St. Croix, Christianssted, St. Lucia and Barbados confirm this result.

A very accentuated depression between 1903 and 1904 is also characteristic for Arequipa and Mauritius as well as St. Helena. The temperature curve of Apia, Samoa Island displays the same very pronounced antipleonian depression completely independent of the formation of the volcanic dust veil of 1902.

Assuming that the volcanic haze produced by the Katmai eruption of June 6, 1912 must have had the greatest effect on the temperatures recorded in Alaska and in Canada, I compared the curves of seven stations in Alaska with the curves of Victoria and Edmonton, Mauritius and Arequipa.

Since Mt. Katmai could not have affected the temperature conditions of Arequipa and Mauritius it is safe to take the curves of these stations as a standard. Moreover in my previous publications I have shown that the consecutive means observed at Arequipa express very well the normal pleionian variation and may serve as a standard in all cases of comparison.

The occurrence of the eruption coincided with the pleionian crest of Arequipa. For Arequipa the consecutive mean of July, 1911 to June, 1912 is the highest. From then on the temperature is decreasing till the consecutive mean of October 1912 to September, 1913. The same at Mauritius.

The curves of the Alaskan stations, the Fort Liscom curve in particular, display practically the same variation as that observed at Arequipa.

The more important conclusions of my research are

The dust veil produced by the Krakatoa eruption affected atmospheric temperature very greatly. The violent volcanic eruptions of 1902 as well as the Katmai eruption of 1912 influenced the yearly mean temperatures but very slightly or not at all.

The pleonimic variations of temperature have nothing in common with the presence or absence of volcanic dust veils.

SPECIAL ARTICLES

ON THE NATURE OF ANTAGONISM

EXPLANATIONS have been suggested by Loeb and others to account for the antagonistic action of various substances on living protoplasm but none of them go far enough to enable us to predict what substances (including both electrolytes and non electrolytes) will antagonize each other and what degree of antagonism will exist between any two substances.

This kind of prediction is apparently made possible by a hypothesis formulated by the writer, as the result of his investigations on the permeability of protoplasm. The testing of this hypothesis has now proceeded far enough to warrant a preliminary statement of its main features.

Substances which alter the permeability of protoplasm may be divided into (1) those which cause an increase but not a decrease of permeability and (2) those which can produce a decrease of permeability.¹

The hypothesis states that substances belonging to the first class will antagonize those belonging to the second, and vice versa. In order to predict which substances will antagonize

¹ Substances which cause a decrease of permeability may, if the exposure be sufficiently prolonged, cause an increase

each other it is only necessary to determine to which of these classes the substances belong. The amount of antagonism may also be predicted at least to a considerable extent, since the greater effect of the substances on permeability the greater will be their antagonistic action. This relation may be obscured by secondary causes, so that the prediction which it allows will not be of equal value in all cases.

To illustrate these relations we may take a series of experiments on *Laminaria saccharina* in which the effects of salts on permeability were determined by electrical measurements. In these experiments it was found that NaCl belongs to the first class, being able to increase permeability but not to decrease it, while CaCl₂ belongs to the second class as it is able to decrease permeability.² It was found that the antagonism between NaCl and CaCl₂ in the case of *Laminaria* is well marked.³ These facts led the writer to formulate the hypothesis stated above. The next step was to test the hypotheses by the investigation of other salts. Magnesium seemed of special interest for this purpose as in most of the writer's previous experiments (on other plants) it had shown no antagonism to sodium though it might be expected on chemical grounds that magnesium and calcium would behave alike. To the surprise of the writer it turned out that magnesium was able to decrease permeability, though its effect was much inferior to that of calcium. The antagonistic relations for *Laminaria* were then investigated and it was found that MgCl₂ was able to antagonize NaCl, though its antagonistic action was much less than that of CaCl₂.⁴

This striking and unexpected result strength-

² The method is described in SCIENCE N. S., 35, 112, 1912.

³ The decrease is followed by an increase if the exposure be sufficiently prolonged.

⁴ Pringsheim's *Jahrb. f. wiss. Bot.*, 54, 645, 1914.

⁵ The means by which the degree of antagonistic action are measured can not be discussed here. One method has been described in the *Botanical Gazette*, 53, 178 and 122, 1914.

ened the writer's confidence in the hypothesis and led to further investigations. One of these which was of special interest related to acids. For a number of reasons it was supposed that acid would not cause a decrease of permeability. But investigation showed that such a decrease actually occurred in the presence of HCl and it was then a simple matter to predict that antagonism would be found between NaCl and HCl. This turned out to be the case, the amount of antagonism corresponding to the amount of decrease of permeability.*

The hypothesis was further tested by investigations on other salts, the most interesting of which are those which (in contrast to those just mentioned) are more effective than CaCl₂ in decreasing permeability, such as La(NO₃)₃, Ce(NO₃)₃, etc. Here also it was found that the degree of antagonistic action could be foretold by observing the amount of decrease of permeability produced by the pure salts. The results of these investigations afford strong support to the hypothesis.

It seems to the writer that the hypothesis offers a rational explanation of antagonism by showing that salts antagonize each other because they produce *opposite effects on the protoplasm* and by stating definitely what these effects are (it should be noted that they have been measured with considerable accuracy).

The soundness of this point of view is indicated not only by the fact that we are able to predict both qualitatively and (to a considerable extent) quantitatively the effect of combinations of salts⁷ but also by the very signif-

icant fact that we are able to extend this conception to organic compounds and to show that non-electrolytes which decrease permeability can also antagonize such substances as NaCl. These facts indicate that the hypothesis may be applied in a general manner so as to include both electrolytes and non electrolytes.

W J V OSTERHOUT

HARVARD UNIVERSITY,
LABORATORY OF PLANT PHYSIOLOGY

ISOLATION OF *BACILLUS RADICICOLA* FROM SOIL

EVER since the epoch making achievement of Hellriegel and Wilfarth reported in 1887, which established the symbiotic relationship between bacteria and legumes in the fixation of atmospheric nitrogen the legume bacteria named in 1901 *Bacillus radicicola* by Beijerinck, have been the object of numerous investigations in all parts of the world. These investigations have assumed a variety of forms and were planned from both the economic and pure science points of view. There has ever remained nevertheless, the unsolved problem of the direct isolation of *Bacillus radicicola* from the soil. Sporadic attempts rather few in number have been made to attain that end, but, what there is may perhaps be correlated with the fact that all substances which decrease permeability do not act alike some producing a much greater decrease than others. Moreover these substances will if the exposure be sufficiently prolonged alter their action and increase permeability. The rapidity of this change varies with different substances and this may be related to the fact that some of these substances antagonize each other to some degree. This will be more fully discussed in a subsequent paper.

Experiments on some plants (in which the criterion of antagonism is not electrical resistance but growth) show a fairly strong antagonism between magnesium and calcium. It is possible that for these plants magnesium belongs in the first class.

It will be noted that the hypothesis, as here set forth, says nothing about the mutual relations of substances belonging to the same class but merely states that substances of one class will antagonize those of the other. In this form the hypothesis is completely justified by all the experiments, including those on organic substances.

* *The Journal of Biochemistry*, 19, 1914

⁷ It should be noted that mixing solutions of two salts which belong to different classes does not produce an effect which is merely intermediate between the two. For example, tissue may be killed by an exposure of 24 hours in NaCl or in CaCl₂, but remain normal in a mixture of these in the proper proportions. Cf. Pringsheim's *Jahrb. f. wiss. Bot.*, 54, 645, 1914.

The writer has found cases in which two substances which can decrease permeability are able to antagonize each other. So far as the writer's experiments with *Laminaria* have gone there is no great amount of antagonism in such cases and

to quote Russell,¹ "none of these organisms (*B. radiculicola*), however, could be found in the soil, nor indeed has any one yet succeeded in finding them there, although their existence can not be doubted." In the literature available to us we have found but one instance in which a claim is made of the direct isolation of *B. radiculicola* from soil not artificially inoculated. That one is the investigation of Gage² who has himself rendered questionable the value of his work by an unfortunately confused use of terminology which has only served to make more difficult than otherwise a comprehension of the present status of the subject. Kellerman and Leonard³ in studying Greig Smith's claim to having discovered a specific medium for *B. radiculicola* could not find experimental evidence to confirm it. Incidentally the last named investigators tried to obtain *B. radiculicola* from different soils some of which grew legumes but were unsuccessful in the attempt except in the case of one soil into which pure cultures of *B. radiculicola* had been introduced after its isolation from alfalfa nodules.

While not deeming the matter one of great moment in any sense, since there can be no doubt, as Russell remarks, that *B. radiculicola* is present in any soil in which nodules are found on legumes, the writers decided to attempt the isolation of that organism and, as a matter of record submit this brief paper in evidence of the success of their attempt. One of us had for three or four years used as a source of *B. radiculicola* for student work in the laboratory the nodules of a large specimen of *Vicia esculenta* growing in the Botanic Gardens on the campus of the University of California, and we therefore decided to attempt the isolation of *B. radiculicola* from the soil in which that plant had grown. The plant had been removed a year or more prior to our initiation of the experiment and the soil had remained bare and unused during that time. Seeds from the plant in question were scattered all over the

surface of the ground and we gathered them for the later tests which are described below. The soil so far as we can ascertain had never been artificially inoculated with cultures of *B. radiculicola*.

Some of the soil just described was taken from below the surface at a depth of about six to eight inches placed in a sterile container and removed to the laboratory. About 30 grams of the soil were there placed in a sterile bottle 150 c c of sterile water added, and the whole shaken after being stoppered, for fifteen minutes. The necessary dilutions were then made for purposes of pouring plates. The agar employed at first was of two kinds. The first was similar to that employed by Fred and was constituted as follows:

- 1 000 grams water
- 10 grams maltose
- 1 gram K_2HPO_4 (separately neutralized)
- 1 gram $MgSO_4$
- 2 or 3 drops each of 10 per cent solutions of $NaCl$, $FeCl_3$, $MnSO_4$, and $CaCl_2$
- 15 grams agar agar

The second was a soil extract agar prepared by dissolving 15 grams of agar and 10 grams of maltose in an aqueous extract from the soil above described. The aqueous extract was obtained by boiling one part of soil with three parts of water for one hour and filtering.

In the preliminary tests the soil extract agar gave by far the better results with both the soil to be studied and with commercial cultures of *B. radiculicola* which were employed as controls. By better results we mean that a larger number of colonies developed on the plates poured with the soil extract agar than on those prepared with Fred's *radiculicola* agar. In the later work therefore the soil extract agar was employed exclusively.

From plates of the proper dilution prepared as above described transfers were made to soil extract maltose agar slants by means of a platinum needle from all colonies which appeared to be characteristic of *B. radiculicola* and in fact of any others which appeared to be different from one another. Transfers were thus made from forty four colonies. After three or four days of growth on the slants, slides were pre-

¹ "Soil Conditions and Plant Growth," D. Van Nostrand Co., 1912, p. 95

² *Cent. für Bakt.*, 2^{te} Abt., Vol. 27, p. 7

³ *SCIENCE*, N. S., Vol. 33, p. 95

pared from all of these organisms and microscopic examinations after several transfers and platings showed the forty four cultures to be pure. The form of the organisms as viewed under the high power of the microscope varied from short to long rods to oval forms. The detailed results of these examinations, however, can not be given in this brief paper.

The next step in the investigation was to test the powers of inoculation of the forty four organisms obtained as above described. Our procedure was as follows. A large quantity of fertile sandy soil from Anaheim, Cal., was sterilized in the autoclave for four hours at about $1\frac{1}{2}$ atmospheres of pressure. When it had cooled it was distributed in quantities making a thickness of three inches in quart size glass fruit jars. The latter were then securely stoppered with cotton and sterilized in the autoclave thus giving the soil a double sterilization. The jars were then put away for three days to allow the soil to become normally aerated again and several samples were carefully withdrawn for testing as to sterility. No colonies developed on the agar plates even after many days. The soil thus being shown to be sterile, we proceeded with the *Vicia* seeds as follows. The seeds were placed in a 1 to 1,000 HgCl_2 solution and kept there for ten minutes. They were then thoroughly rinsed with distilled water and treated with concentrated H_2SO_4 for 20 minutes to aid germination. They were then again thoroughly rinsed in sterile distilled water and removed to a sterilized moist chamber containing several layers of water saturated filter paper. The seeds which thus gave perfect germination in 3 or 4 days as against very poor germination for similar seed untreated with H_2SO_4 , were then transferred to the jars with sterile forceps and pressed into the soil by means of a sterilized glass rod without removing the stoppers from the jars. It may be added here that every jar received fifty c.c. of a 5 per cent dextrose solution to furnish optimum moisture conditions and a proper source of energy for *B. radiclecola*. Five seeds were planted in every jar and the inoculation was accomplished by

the addition in every case, of a 5 c.c. suspension of the agar slant culture with sterile distilled water. The jars were removed to the greenhouse and remained there for fifty-four days, sterile distilled water being carefully added when necessary. All the plants in all the jars appeared to grow equally well and attained a height of about eight inches. Evidently there was an ample supply of nitrogen in the ammonia or closely related forms to supply even the plants in the five control jars which received no inoculation. Besides the control jars and the forty four others above described there were five jars inoculated with commercial cultures as follows: (1) Farmogerm, (2) Nitrogen gathering Bacteria, (3) Ferguson's Nitrogen Fixing Bacteria, (4) Mulford's Nitro Germ (weak culture), (5) Mulford's Nitro Germ (strong culture). After the period mentioned the plants were carefully removed from the soil in every jar and the roots examined, with the following results:

1 No nodules were found on the roots of any of the plants in the control jars.

2 Twenty one of the forty four inoculations with bacteria isolated from the soil above described gave positive results and nodules were found on the roots of some or all of the plants in those jars.

3 The balance or twenty three inoculations gave negative results and none of the plants in those jars showed the presence of nodules on the roots.

4 All the commercial culture inoculations produced nodules except the weak culture obtained from one of the Mulford transfers.

These results would seem therefore to record the first isolation, so far as we know, of *B. radiclecola* directly from the soil, to show that that organism so obtained at least in some forms and places can be readily made to grow on agar plates in large numbers, and to make desirable the use of soil extract-maltose agar for such purposes.

The writers will welcome criticisms of their work which may occur to their colleagues, and to be corrected if, in error, as to priority (excepting Gage's investigation) so far as the recorded isolation of *B. radiclecola* is con-

cerned. Many other facts of interest besides those above discussed have come to light in our investigation, but the limited space of this paper will not permit of their discussion, nor of the submission here of the detailed data which furnish the basis for the discussion above given.

I. W. FOWLER

THE AMERICAN PHYSICAL SOCIETY

The seventy-fifth meeting of the Physical Society was held in Randall Morgan Laboratory of the University of Pennsylvania, December 29, 1914, to January 1, 1915. It was a joint meeting with Section B of the American Association for the Advancement of Science. Morning and afternoon sessions were held on Tuesday, Wednesday and Thursday. Vice-president Anthony Zeleny, of Section B presided on Tuesday and Wednesday afternoons, and President Merritt at the other four sessions.

On Tuesday afternoon the program consisted of the Vice-presidential Address before Section B on "Recent Evidence for the Existence of the Nuclear Atom," by A. D. Cole, and the presidential address of the American Physical Society on "Luminescence," by Ernest Merritt. On Wednesday afternoon there was a symposium on the "Use of Dimensional Equations," led by E. Buckingham, who was followed by A. C. Dunn, A. G. Webster, W. S. Franklin and others.

The following program of papers was presented:

"An A.C. Bridge for the Measurement of the Dielectric Loss and Dielectric Constant at High Voltages and Low Frequencies," by Chester A. Butman.

"Influence of the Concentration of Electrolyte upon Electrode Potentials," by Arthur W. Ewell.

"A New Method of Obtaining a Hysteresis Loop," by W. N. Fenninger.

"On Rotation and Magnetization," by S. I. Barnett.

"Note on Thermo E.M.F.'s in which the Resultant Peltier Effect is Zero," by H. C. Barker.

"Linear Resistance Change with Temperature of Certain Molten Metals," by E. F. Northrup.

"The Effect of Temperature on the Dielectric Strength, the Dielectric Loss and the Dielectric Constant of Paraffine Oil," by Chester A. Butman.

"A Preliminary Note on the Variation of Stray Power Losses in a Dynamo," by W. N. Fenninger.

"Relation Between the Energy of the Cathode Rays and the Frequency of the X Rays Produced by Them," by William Duane.

"Thermionic Currents from a Wienelt Cathode," by W. Wilson.

"Mobility of Ions at Different Temperature and Constant Gas Density," by Henry A. Wilson.

"The Radioactive Content of Certain Minnesota Soils," by James C. Sanderson (Read by H. A. Erikson).

"Conducting Gas Layer at a Metallic Surface," by G. W. Stewart.

"X Rays From the Electrical Discharge," by Elizabeth R. Laird.

"X Rays Produced by Slow-moving Cathode Rays," by Elizabeth R. Laird.

"Light Due to Combination of Ions," by C. D. Child.

"Electric Furnace Evidence on the Relation of Spectrum Lines Having Constant Differences in Wave Number," (by title), by Arthur S. King.

"The Mechanical Equivalent of Light," by H. L. Ives, W. W. Coblentz and E. F. Hughesbury.

"Fluorescence of the Uranyl Salts under X-Ray Excitation," by Frances G. Wick.

"The Efficiency of Energy Transformation in the Corona With d.c. Rectipitating Tubes," by W. W. Strong.

"Penetration of Gas Through Quartz Tubes," (by title), by F. C. Mayes.

"A New Method for Measuring Gravity at Sea with Some Trans-Pacific Observations," by Lyman J. Briggs.

"The Oxidation of Nitrogen," by W. W. Strong.

"The Alleged Dissymmetrical Broadening of the D Lines of Sodium," by I. A. Fikharit.

"Exhibit of Mechanical Models Illustrating (a) Subdivision of Alternating Current Between Two Branches in Parallel, (b) The Alternating Current Transformer, (c) Coupled Circuits in Wireless Telegraphy," by W. S. Franklin.

"Some Causes of Variation in the Sensitivity of Moving Coil Galvanometers," by Paul F. Klopsteg. (Presented by A. Zeleny).

"A New Standard Phone and Phonometer for any Pitch," by A. G. Webster.

"A New Form of Radiation Pyrometer," (by title), by S. Leroy Brown.

"The Doppler Effect in X-Ray Spectra and Application to the Kinetic Theory of Solids," by L. Gilchrist and D. A. Keys.

"On Acoustic Impedance and an Approximate Theory of Conical Horns," by A. G. Webster.

"Vapors with Positive Specific Heat in Energy Conversion," (by title), by J. F. Siebel.

"Progress of B-Particles through Matter," by A. F. Kovarik and J. W. McKelhan.

"A Thirty-two Element Harmonic Synthesizer," by Dayton C. Miller.

"The Result of Plotting the Separation of Homologous Pairs against Atomic Numbers instead of Atomic Weights," by Herbert F. Ives and Otto Stuhlmann.

"Beaded Lightning," by W. J. Humphreys.

"A Practical Measurement of Colors," by H. E. Wetherill.

"Preliminary Note on a Mercury Vapor Tube," by H. E. Wetherill.

Oscillator,' by B Liebowitz (Introduced by M I Pupa)

On Tuesday evening a public lecture, complimentary to the citizens of Philadelphia and illustrated by experiments and the lantern, was given by Dayton C Miller. On Wednesday evening a successful dinner for physicists was arranged by Professor H C Richards at the Hotel Normandie. This was enjoyed by about seventy members. The members of the society were the guests of the University of Pennsylvania at lunch each day of the meeting. The registration of the meeting was 117. The attendance at the various sessions was exceptionally in form and varied between 100 and 150.

A D COLE,
Secretary

SOCIETIES AND ACADEMIES

THE BOTANICAL SOCIETY OF WASHINGTON

The one hundredth regular meeting of the Botanical Society of Washington was held in the Crystal dining room of the new Ebbitt Hotel, at 614 M. December 1, 1914. One hundred and four members and eight guests were present. A dinner was served at which were featured several dishes made from plants which have been introduced to this country by the U. S. Department of Agriculture. Drs. W. Ralph Jones, J. S. Cooley, H. V. Harlan, and Messrs. G. F. Gravatt, G. H. Godfrey, I. M. Hutchins, Paul Popenoe, and R. G. Pierce were unanimously elected to membership. The remainder of the evening was given to a special program dealing with the early history and growth of the society with the following papers:

Mr. M. B. Waite, 'The Botanical Seminar and the Early Development of Plant Pathology in Washington.'

The Botanical Seminar was founded in 1893. The purpose of the members was to make the meetings as informal as possible. The monthly meetings were held at the rooms of the various members. There were no officers other than the speaker of the evening, who usually was the person entertaining the Seminar. There was no constitution or by-laws. Refreshments were served and very frank discussion and criticism was encouraged. In 1901 the number of candidates for membership became so great that this method of holding meetings became impossible and the Botanical Seminar was merged with the Washington Botanical Club to form the present Botanical Society of Washington. The speaker sketched briefly the development of the work in plant pathology

in Washington from the early beginning when the pathological work was a very small branch of the botanist's duties, up to the present large body of investigators.

Letters from the Boys in Washington. Mr. DAVID FAIRCHILD.

This consisted in the reading of actual letters from various early workers in plant pathology and physiology and brought home to those present the actual condition of things at that time more vividly than could have been done in any other way.

The Washington Botanical Club. Dr. EDWARD L. GREENE.

The Washington Botanical Club was founded in 1898 with a very informal organization quite similar to that of the Botanical Seminar. The Botanical Club included more especially the workers in systematic botany. Dr. Greene was the first and only president. In 1901 it was merged with the Botanical Seminar to form the Botanical Society of Washington.

Systematic Botany. Mr. F. V. COVILLE.

Mr. Coville gave briefly some of the more important features of systematic botany in Washington from the early days up to the present time, emphasizing the use of types of species which was a direct contribution of the United States Department of Agriculture.

Early History of Physiological and Plant Breeding Work in the Department of Agriculture. Mr. WALTER T. SWING.

This briefly sketched the beginning of the now extensive work in plant pathology and plant breeding in the U. S. Department of Agriculture.

On Tuesday, January 5, 1915, at 8:30 P. M., the Botanical Society of Washington met in joint session with the Washington Academy of Sciences in the Assembly Hall of the Cosmos Club. Professor J. C. Bose gave an illustrated lecture on 'The Response of Plants.'

The one hundred and first regular meeting of the Botanical Society of Washington was held January 9, 1915, at 1:30 P. M., in the west wing of the new Department of Agriculture building. Thirty-four members were present. Messrs. F. Traub Hubbard, Howard S. Coe, Luther P. Byars, and Dr. L. O. Kunkel were unanimously elected to membership. The resignation of Mr. H. C. Gore, as treasurer of the society, was accepted and Mr. C. E. Leighty was elected to that office. No scientific program was presented.

PROBLEMS OF GEOGRAPHIC INFLUENCE¹

FOUR points of view will be taken with reference to our theme: its importance, its difficulties, the related sciences, and fields of investigation.

We deal here with the heart of geography. The ties, infinite in number, which bind life to the earth lead surely up to man. No other phase is so insistent and so appealing as the earth's influence upon our kind. The plant and animal world joins itself to our physical habitat to enrich our environment and multiply our problems. The first members of this association came into it from the field of geology, and these men have from meeting to meeting and from year to year marched steadily up toward the human goal of our science. In Mr. Roorbach's recent symposium on the *Trend of Modern Geography*,² by far the larger number directed their call for research toward the field of geographic influence. Whether we speak of influence, or response, or adjustment matters little. Terminology will grow unbidden, if we are exact in our thinking.

Here lies the weight of our theme. We all have a duty to do in view of the ill-founded and doubtful conclusions too often set forth, and in view of the vast extent of the unknown in this field. The factors of influence are not carefully isolated. What these forces really do and how they do it are not shown. Ripley holds it certain "that the immediate future of this science

¹ President's address before the Association of American Geographers, read at the eleventh annual meeting, Chicago, December 30, 1914.

² "The Trend of Modern Geography," *Bull. Am. Geog. Soc.*, November, 1914.

will depend upon the definiteness with which its conclusions are stated and illustrated."³ The rich and sometimes noble and rousing periods of Ratzel leave us often in the jungle of thought. But he made a trail in the jungle, and we who follow the trail may not blame him for unexplored corners of the forest. What Ratzel thinks about definite knowledge appears in his criticism of the so-called "climatic philosophers."⁴ Here too Brunhes adds his call for precision:

How does the climate influence us . . . it is just as necessary here, as elsewhere, perhaps more necessary, to rejuvenate current assumptions by analyzing them, for they are far too slipshod and superficial.⁵

This call for definiteness presses on every student of geographic influence, be the phase climatic or other. It is not that we can draw mathematical conclusions in any science of man, but sharp eyes and good logic will at least lift us from chaos to order.

We are thus under bond to work this field for the perfection of essential geography. But we owe a further debt, or rather, there is a mutual exchange of help in which we must not fail of our part. Geography offers help and cooperation to all sciences that deal with man, anthropology, ethnology, history, sociology, economics, psychology and comparative religion, and from each of these geography will gather data for its own perfecting.

The historian, for example, needs from the geographer a more full knowledge of environmental working, and the geographer receives in turn much from the historian. The old geography knew little of the causal and historical, and some of the old history might just as well have been staged on a

flat platform projected into the interplanetary ether.

If history is to strike deep roots into the earth, if it is to set forth with full discernment, the moulding, moods, motives and movements of men, the historian will need help from the geographer; and the historian, sceptical of generalizations that are too easy and scorning overstatement, will respond with open hand to every real offering of the geographer.

When geography was poorer than today, Parkman wrote the human story out of its environment. James Bryce has always and without stint placed geography in the running with historical movements. And if the generalizations of Bryce, like those of Ratzel, are sometimes tinged with vagueness, let us blame, not the historian of broad outlook, but the geographer whose work is yet in arrears. Other examples are not wanting. Winsor, in dedicating this Mississippi Basin to Mr. Markham, then President of the Royal Geographical Society, writes of environment,

I would not say that there are not other compelling influences but no other control is so steady.⁶

Mr. Edward John Payne has written a "History of the New World called America." Being no historian, I do not know the craft's estimate of that work, but I am astounded at the author's deep and broad knowledge of environment in the lands whose story he tells. The surface, the climate, the possibilities of cereal production and of the domestication of certain animals appear in such wise in relation to early American civilization, to the arts and habits of the people, as to stir the geographer to admiration. Whether all of Payne's conclusions stand fire or not, he gives an example of effort aimed at preci-

³ W. Z. Ripley, *Pol. Sci. Quar.*, 10, 640.

⁴ "Anthropogeographie," I, 83-84.

⁵ J. Brunhes, Inaugural lecture, *Scot. Geog. Mag.*, 29, 312.

⁶ "Mississippi Basin," Justin Winsor, *following* title page.

SION This is a call to every geographer. The geographic atmosphere in Professor Turner's story of our north central west is known to us, and Professor J. L. Myres, reaching at once broadly into the fields of classic lore, anthropology and geography, is, in his person and work, living testimony to the importance of our anthropogeographic task, and to the hopefulness that lies in our attempting it.

Some historical writers are influenced little if at all by the study of the earth and lower life as elements of human environment. Even volumes professing to deal with the geographic foundation of history sometimes fail of their goal, and one preface affirms that—"the general physiography of North America is familiar enough to readers."

This, I am sure, is quite too rosy a view of the geographic situation. But I cite the limitations of some histories in no mood of criticism. Let every man build the wall over against his own house. What of assured fact or proven principle we put before the historian he has neither the will nor the power to escape. Our light is in no danger of being put under a bushel. But we have good need to see that it is lighted.

Who can show me a good human geography of Greece? Perhaps it is now in the making by a member of this association. If there be such a work, should it be possible for a historian of Greece to liken Asia Minor and Egypt to enormous jaws about to swallow Cyprus, to describe the Egean and Adriatic as *fjords*, to liken southern Europe to a mastodon, Greece being a leg, to call Greece with its mountain spurs and bays a skeletonized leaf, to fill the peninsula with tiers, storeys, waists, claws, wheels, threads and tongues, and leave you not knowing whether this poor little country is a house of many rooms or a spider with sprawling limbs. But we are most

gravely assured that the geography of Greece had results upon its history, and diversity of states formed by diversity of surface is the lone geographic captive shut up in this dark closet!

If we turn to sociology we meet the insistence on the importance of environment. Let us take Giddings's definition, that

Sociology is an attempt to account for the origin, growth, structure and activities of society by the operation of physical, vital and psychological causes, working together in the processes of evolution.

Or we may cite the utterance of Small, that "this force is incessant, that it is powerful that it is a factor which may never be ignored." Yet Dr. Small in an extended chapter on environment mentions geography but once, and then not as a science which might contribute to sociology. Professor Ridgeway² thinks that failure fully to recognize man as controlled by the laws of the animal kingdom leads to maladministration of alien races and blunders in social legislation. He says, further, "As physical characteristics are in the main the result of environment, social institutions and religious ideas are no less the product of environment" and again any attempt to eradicate political and legal institutions of an equatorial race "will be but vain for these institutions are as much part of the land as are its climate, its soil, its fauna and its flora." Ripley, in reviewing the second volume of Ratzel's anthropogeography, criticizes the author for neglecting acclimatization, considering its importance in social theory, and in view of the fact that theories of race dispersion turn upon our judgment in this matter. Perhaps the real state of the case is seen in the appearance

¹ "General Sociology," A. W. Small, 417.

² Wm. Ridgeway, "The Applications of Zoological Laws to Man," *Brit. Assoc. Adv. Sci.*, Dublin, 1908, 832-847.

not long ago of a serious and careful volume on the development of western civilization, which nevertheless exhibits an utter dearth of geographic data and principles.

We are safe then in saying that most authorities in these sciences of man recognize environment as fundamental, but the greater part, in a sort of absolution of conscience, name the subject and take leave of it.

We need not therefore expect the historians or the sociologists to develop in any full way the principles of environmental action. They admit the need of these principles, but have not the time, perhaps not the will, to develop them. It remains for us to put content into the word environment, so that it can not be overlooked or slighted and so that its meaning may be come available in plain terms to all.

In his "Racial Geography of Europe" Ripley asserts that

To day geography stands ready to serve as an introduction as well as a corrective to the scientific study of human society.

This was written about twenty years ago, and yet it is to day not so valid or truthful a statement as we could desire it to be. Our convictions are in the right place and much has been done, but we still suffer from a dearth of limited, local, special and proven data, and a surplus of generalizations announced with the enthusiasm of fresh discovery, or rediscovery, unsupported by adequate evidence. We are subject to Marett's criticism of certain generalizations of Ratzel and La Play—"too pretty to be true"¹⁰. We are awaking to the importance of our field and this is well, but it is equally important to make haste slowly and to give human geography a content satisfying to ourselves and convincing to our fellow workers in adjoining fields.

The pursuit of our theme is as difficult as

it is important. Professor Cramb in a recent book¹¹ comments on the causal idea so common in our modern thought about history. His word is equally good for us. He says

In man's history nothing is more difficult than to attain to something like a just conception of a true cause.

Universality and necessity are the criteria which he proposes. A stiff application of these principles would be a tonic for some geographical theorizing.

Here is an individual, X, What is he? He is first a bundle of anatomical characters. How did he get them? Why is he different in these matters from some other man? A single example will show how little we know. Professor Boas well says that "haphazard applications of unproved though possible theories can not serve as proof of the effectiveness of selection or environment in modifying types"¹². He calls for comparison of parents of one environment, with their children reared in another. He has made such investigation upon children of immigrants in New York City and concludes that distinct changes, as of head form, took place¹³. He has done well, no doubt, all that one piece of investigation permitted. But he does not analyze the factors of change nor show what any factor does. Alongside of these apparent changes in one generation we may put an opinion of Professor Myres, who, referring to a common belief that Alpine man originated in the Alpine region in response to environment, states his conviction that the time since the glacial period would not suffice for so great a change of head form¹⁴.

* R. B. Marett, M.A., "Anthropology," 98

Lester F. Ward is equally confident that

There has been no important organic change in man during historic time.¹⁴

Our individual also embodies physiological and psychical activities which are affected by environment. Here the problem is immensely involved for, as Brinton says, psychical development depends less on natural surroundings than on a plexus of relations of each man with many others.

Natural environment includes first the physical—soil, water, minerals, land form, temperature, moisture in the air, light, electricity, and all operative on an earth in interplanetary relation to the sun. Then is added the animal and plant environment whose daily pressure on the individual and the group has held in no small way the destinies of civilization. Interwrought with all these natural forces are the human social factors ever more powerful since the dawn of history. Thus there is a total of infinitely variable factors producing infinitely diverse results upon the body and mind.

The environment of this day and hour is perplexing enough, but environments change. Man exchanges one environment for another. The steady drive of our environment in its daily flux is replaced by the shock of a new environment entered in a day or a night or gained by long voyages across the sea. The sum of a man's heredity goes out into his new sphere with him. But how much of this is primal and persistent and how much can be shifted like a garment? The heredity doctors have not answered this question and geographers should have a care. It is a wholesome corrective to remember the number of our possible ancestors. According to Boas,¹⁵ an Eskimo could not have so many as you or I. Royal families share this limitation with

the polar man, and one European monarch, it is said, has in the past twelve generations only the meager outfit of 533 ancestors out of a theoretical 4,096. We, however, belonging to a large population of unstable habits might have in twenty generations more than a million each. We are too complex to come to an easy reckoning about ourselves.

By our social memory we carry the old environment into the new, and thus we 'compound'¹⁶ environments, and thus ends in making environment coextensive with the world. The universality of modern environment for any civilized man appears in our commercial interchange and speaks to us in a war whose center is in Europe, whose circle takes in the world.

Ratzel in showing how Christianity conquered its realm not as direct from Palestine but as modified on its way through Egypt, Greece and Rome has given us a good example of such compounding of environments.¹⁷ Geographers have by no means been blind to the difficulty of anthropic problems. Brunhes warns us that truth in geographic relations of man is approximate, and that to claim it as exact is to be unscientific.¹⁸

The outstanding psychological fact then is the antithesis of a rigid fatalistic determination of human acts by climate and soil.¹⁹

And he then cites what he calls "antinomies" frontier, urban, racial, and social. Ratzel has a most instructive passage on sources of error due to the neglect of middle members lying between visible workings and their remote causes, the inclination to take a direct line instead of the roundabout way of mediate working causes. This

leads either to false results or to the hopelessness of reaching the truth²⁰

Professor Myres in the closing lines of his little book, "The Dawn of History," admits and emphasizes the vagueness of results in trying to estimate the relations of history, geography and biology. But his final word is of good cheer,

If the reader is moved to complain with that other, "I see men as trees walking," let him remember that he who said that, was well on the way to see every man clearly."

Thus far our notice of our difficulties has been general. Let us look at the questions of race. "Race is the key to history—what is the key to race?" Thus Griffiths inscribes the title page to a volume on Japan. In estimating the force of a given environment on a given time how much shall we allow for race? But we must go back of that. How did environment go into the making of race? But suppose we are not sure what a race is and can not with any agreement analyze and classify present races! Authorities agree neither upon race nor upon the efficiency of race in relation to environment. Thus one authority assigns a race cause for the higher status of long heads as compared with broad heads in certain parts of France. The long heads have more wealth and pay more taxes than their brachycephalic countrymen. Is this really a racial result? Or is it due to a fortunate occupation of richer lands, bringing in its train the higher professional and social status and the urban tendencies of the northern blonds? The criteria of necessity and universality need to be pressed home.

The present writer has difficulty, being a layman, in understanding the ethnologists when they classify races. It is increasing to one's comfort therefore and saving to self respect to find a member of the anthropological fraternity saying of the develop-

ment of races that it is "immensely difficult to separate the effects of various factors," and that, "it is not edifying to look at half a dozen books upon the races of mankind, and find half a dozen accounts of their relationships having scarcely a single statement in common. Far better to face the fact that race still baffles us almost completely."²¹

We may add a further observation, that much in this field depends upon paleogeography, if we are to decipher the origin and migration of races. But here, as Marett says, is a rather kaleidoscopic science, for the continents and bridges which it calls up out of the ocean have a way of crumbling.

Let us illustrate by the so called Aryan question. It used to be an item in the ethnological creed that most European peoples using languages of cognate features came thither from central Asia by the way of India. But many years ago now it was shown that common language did not prove race kinship. Nor do names of trees and other plants suffice to trace migrations, for men change the names of their trees, and floras migrate in the long marches of time. It has been remarked that if we had no historical knowledge to the contrary, *tobacco* and *potato* might be taken as parts of a European tongue, rather than a loan from the Caribbean natives.

So come the measurer and the calipers in place of the linguist and set up the physical criteria of head form, stature and color and put in place of a comfortable and discredited generalization the chaos of opinion which is often the precursor to more fixed and defensible conclusions. But such conclusions have not yet been reached. So uncertain is the status of the problem that one writer on the sources of the Germanic invasions says that while some put the origin in Africa, others trace racial dif-

²⁰ "Anthropogeographie," I, 54

²¹ R. B. Marett, "Anthropology," 61

ferences to environment and others fall into skepticism about the whole matter.²² This author thinks the Germans are diverse, as a Roman might be anything from York to New Carthage, Corinth or Damascus.

Brinton holds that the origin of this so-called Indo European group was in the west the central Celtic tribes moving from the Atlantic region through the Alps to the Danube, a southern series of offshoots peopling the Mediterranean and the northern, moving southward and eastward from primitive seats on the North and Baltic seas.²³ Another authority thinks with Sergi and Keane that the Mediterranean stock came from Africa and that the dolicho blond developed after the passage to Europe and the initiation of the Mediterranean water barrier.²⁴

Ridgeway²⁵ on the other hand makes two non Aryan races in Europe, Alpine and Neolithic, overrun by two Aryan races, once thought to have come from Hindu Kush, now believed to have originated in upper central Europe. He argues that to follow Sergi in making the Mediterranean race non Aryan "leaves out of sight the effects of environment in changing racial types and that too in no long time." He cites the cases of the Boers in Africa and of New World natives changing their latitude. There was gradual change from the short, dark men of southern Europe to the tall blonds of the Baltic. This means more than intercrossing and raises suspicions of constantly working climatic influence. He

thinks environment the chief factor in stature and pigmentation. Attention to other animals, in Ridgeway's view, demonstrates this doctrine. He cites the white hares and bears and the tendency of the ptarmigan and the horse to turn white in winter. The horse is cited as shown in varieties from northern Asia to the Cape of Good Hope, and this writer concludes that environment is powerful not only in colorations but in osteology, and that these changes may be very rapid. The blond Berbers are believed to owe their qualities not to mixing with Vandals and Goths but to being cradled in a cool mountain region. The fair haired people have poured for centuries across the Alps and yet hold their own only in the north of Italy. Woodruff does not think they were darkened but that natural selection eliminated them because they went beyond their latitude range. *Homo Alpinus* is held by different authors as Aryan or as Mongolian from Asia and as having evolved their brachycephalic character on European soil.

Marett referring to Ridgeway, thinks he overrates environment but admits it as premature to affirm or deny that in the *very long run*, round headedness goes with a mountain life.²⁶

To add other items of opinion confirming the conviction that much fruit has set, but few specimens have ripened. Marett places in north Africa the "original hot-bed"²⁷ of the Mediterranean race who in Neolithic times colonized the north shore of the Mediterranean and passed by the warm Atlantic as far as Scotland. The same author, keeping close to cover, says that it is now fashionable to place the Teutonic home in northeastern Europe, though he regards it as still something of a mystery. The Scandinavian origin of Euro

pean peoples is held by some²⁸ while J. L. Myres shows the affinity of boreal and Mediterranean man and suggests their Euro-African origin,²⁹ and Gray's discussion of Myres's paper emphasizes the swift action of environment.³⁰

Altogether it is hardly to exaggerate to say that you can find authority for placing the breeding grounds of the European peoples in north Africa, in central Asia, or in any part of Europe, for sending their wandering progeny in any direction of the compass, with any kind of racial mixture or linguistic evolution and with every possible shade of efficiency or inefficiency on the part of environment.

But suppose the Aryan business cleared up, there would remain earlier problems of Paleolithic differentiation and the prolonged twilight journey of man. And suppose we had threaded our way, geologic, ethnographical, linguistic, and geographic, down through the differentiations and mixtures and migrations until we have the Teuton and the Celt in north Europe and the British Isles, are our troubles past? Let us see.

You would trace the evolution of the American, as effected by environment. Where will you begin? Not in New England or Virginia. Not altogether in old England. Not altogether in Teutonic Europe. Before we got through with the American we might like to cover all Europe with the network of our inquiry. But we can not move too broadly, let us turn to the British Isles. There are still the progeny of the pre Celts of Neolithic age. There came at least three types of Celt, the Gael, the Briton and the Belgæ. Roman

invasion and rule followed and in due time the Christian religion. Next came the Angles and Saxons and Jutes from across the North Sea, a new deluge of paganism, and a new contribution of racial traits bred in the long past. One would like to know how that old North Sea Teuton differed, fifteen centuries ago, from the Baltic Sea Teuton of the Prussian plan. Was it in the latter's great strain of Slavic blood, or were there other factors? When and where did the present sum of difference between Prussian and Englishman begin to emerge? At any rate, Jutland, Schleswig-Holstein and the lowlands of the Elbe were poured into our ancestry and were Christianized.

In the eighth century the Viking rovers came across the North Sea with fresh cargoes of vigor and paganism. The Rhine, Scheldt, Seine and Loire as well as Britain felt their power. "From the fury of the Northmen save us, Lord," runs an old litany. But pirate and robber though he was, here was an element of selection that must not be disregarded. Norway, Sweden and Denmark says Greene, "were being brought at this time into more settled order by a series of great sovereigns, and the bolder spirits who would not submit to their rule were driven into the seas and embraced a life of piracy and war." But there had been bred into them "in a land that is one third water and one third mountain, where winter lasts six months in the year, endurance, ingenuity and daring."

In two or three centuries more followed the Norman Conquest, in which the Viking brought to England all that he had taken on and taken in of French life. There follows the further coordination of Neolithic, Celtic, Teutonic and Norse men for five and a half centuries, until the early decades of the seventeenth century and the beginnings of British settlement in America. And this was a selective migration whose story can

²⁸ Richard, "History of German Civilization," Ch. II.

²⁹ J. L. Myres, "The Alpine Races in Europe," *Geog. Jour.*, 28, 537.

³⁰ *Ibid.*, 555-56.

not be told here, and has never been so fully told as the student of environment might desire. Suffice it to add that no mere paragraph can tell us what kind of people came to Massachusetts, or Virginia. Religious, economic and political changes in England, plus the attractions of a fresh world, brought across the sea the elements that have been formative in American life. American environment has not developed all the qualities which we consider as distinctively or typically American.

But in New England, and on the Hudson, the Delaware and the James, new physical and social pressures began to wield their power. After some generations in this environment in the eighteenth century, a new flow began through the passes of the Appalachians. To Timothy Dwight is ascribed the view that thus New England was rid of her restless and insubordinate spirits. Another interpretation is that the best and most progressive men went because they did not like the rule of the Congregational clergy. At any rate, it was another selective migration, by which picked families went into a new environment. Turner is our best authority for what the environment of the middle west made out of the emigrant from the East. It would be easy to show, I think, that in spite of what might seem predominating mixtures of Continental European migration, New England still pervades Wisconsin, that the New England mind was more powerful than the new environment, important as that was, just as the Puritan mind was more powerful than the New England environment.

The selective emigration moved on by prairie schooner and transcontinental railway to the Rocky Mountains, the intermont plateaus and the Pacific Coast. Here are mountains, deserts, mines, giant forests, irrigation and a new ocean. Whence

came the Californian? From New England, Ohio, Iowa, Kansas, Colorado. Is that all? Every one of the following regions is there, with 5,000 to 200,000 representatives: Germany, Ireland, England, Canada, Italy, Mexico, Russia, Scotland, Sweden, Switzerland, Portugal, Norway, France, Denmark, Austria, Wales, Turkey, Spain, Greece, China, islands of the Atlantic, Australia. The German, Canadian, Englishman, Spaniard and Russian that wanted to be or do something new are there. And it is a compelling environment, of sky and mountain, ocean and plain, forest and desert, mine and field. Professor Royce, a native Californian, thinks the typical character there is a combination of strength and weakness, with wandering in the blood, lack of social responsibility, recognition of no barriers, desire for sudden wealth, love of difficulty, unaccented love of home, with more love of fullness of life than reverence for the relations of life.¹¹

One more picture of this western life must here suffice—it is by a journalist—of the American of the far northwest, where New England and the *Mayflower* appear not, whose men followed the Missouri from Kentucky, Indiana, Missouri and Arkansas, tall, big boned, and stalwart, self assertive, nervous, quick in action, acting before they think and thinking mainly of themselves, their European origin so far behind them that they know nothing of it. Their grandfathers had forgotten it. In a word they are distinctly, decidedly, pugnaciously and absolutely American.¹² Making what allowance you will for Ralph's exuberant rhetoric, and Royce's habit of philosophizing, better to be solved in the twenty first century than to-day is the

¹¹ J. Royce, "California," *Am. Com. Series*, 499-500.

¹² J. Ralph, "Our Great West," 141-42, quoted in abstract.

problem of the function of environment in shaping American life. As we have seen in this sketch, the geographer will not work alone, the historian, sociologist and philosopher will take a hand.

It's a long way from the primitive man to the differentiation of the white race, from the white beginnings to Briton, Anglia, Norway and Normandy, from Anglia and England to California and Puget Sound. Along this ancient and devious path our ignorance of the inner laws of human development is appalling. We see man and earth, something called race, race continuity, one physical environment after another, human environments with innumerable mixtures of blood, in infinitely various compounds, in the grand march of humanity to one world center after another. The result, to carry out our illustration still, is the Pacific coast man, domestic, industrial, political, social, moral. It will take cautious steps and many torches to pick our way back along the road by which he came.

Let us take another example in emphasis of the difficulties which beset us—an analysis of the causes of Japanese character. Mental alertness has been asserted to be the chief trait of the Japanese. This must have originated in accordance with biological laws, in spontaneous variation, in mixture of races, or in environment, or we might add, by a combination of these. It is tentatively held that however this quality arose, it has been preserved by environment: first by insularity, giving familiarity with the sea, saving from wars, intermixtures and invasions, in distinction from a continental land, like China; second, by physical features, affording small areas of cultivation, promoting industry, a land of such richness as to give certainty of reward, without drought or flood to destroy the prudent as well as the thriftless. Third,

there comes climate, following a supposed law that the progressive lands are in the cyclonic domain of the Temperate zone.

This seems simple, interesting and suggestive, but is it true? Is mental alertness the chief trait in Japanese efficiency? Droppers, sometime professor in the University of Tokyo, thinks the secret of success is in the structure of society, devotion to family life or to tribe and nation, the corporate versus the individualistic.³³ Dyer emphasizes community but denies that the main ability is in imitation. Loyalty and intellectual ability are the basis of achievement. Another authority marks the Japanese as sober, intelligent, enduring, patient, industrious, polite, skilful, ready to assimilate, not devoid of original genius.³⁴ Yet another says he is patient, persistent, cheerful, versatile, quick-witted, enterprising, original, imitative, progressive, industrious, artistic, humorous, cleanly, polite, honorable, brave, kind, calm, self-contained.³⁵ Whether any good human qualities have been left out of these catalogues we do not know, but we are at least left in doubt as to what the main national trait is.

But suppose it is mental alertness. Would insularity make it or keep it? Miss Semple avers that insularity breeds conservatism, a quality that does not seem to be indissolubly tied to alertness. Insularity may give familiarity with the sea, but perhaps not greater than is true of the Dutch, who are not insular, and we do not think of the Dutch as distinctively alert. Insularity has not kept Japan free from invasion, though there have been periods of seclusion. And the modern Japanese are

³³ Garrett Droppers, "The Secret of Japanese Success," *Your Race Devel.*, II, 424.

³⁴ V. Dinglestedt, "Ruling Nations," *Soot Geog. Mag.*, 27, 305.

³⁵ Writer in *New Inter. Ency.*, Art. "Japan," 335.

"a very mixed people," Mongolian, Caucasian, Malay, and some say an infiltration of Negro. If insularity breeds alertness, what other factors have apparently swamped this tendency in Madagascar, Iceland, Sicily, Cuba and Hawaii?

Nor can we be sure of the effect of small areas of rich cultivation and certain reward. Industry we can predict and a degree of comfort, but can we say more? Why not as well expect the Belgian farmer or the farmer of the Paris basin, or of the county of Norfolk to be mentally alert? Moreover most Japanese are in a low state. "We imagine them" (the Japanese) "as intellectually homogeneous," but there are "five million highly cultivated people and nine times as many of lower type the mighty mass still pagan, stolid, low in the scale of evolution."³⁵

This little empire is indeed a good place in the temperate zone, and so are China, Switzerland, Spain, Austria-Hungary, Germany, France, and too many others to make the criterion of distinctive value. The inference for precise, detailed and prolonged research need not be elaborated.

We have already spoken of certain related sciences as supplying motives to the human geographer. We turn now to examine the geographer's proper sphere of activity in relation to these sciences.

Our references to the race problem might seem superfluous for if this field belongs essentially to the anthropologists, what right has the geographer there? Here we seem at once to need a definition of geography. But the present writer will not try to go where angels have trod with devious and faltering steps. Some time we shall have a definition of geography, but not now. Meanwhile we have enough to do, and if we are reviled as devotees of patchwork, as

having no real science, we bear it with serenity.

I do not know of any one who proposes to rule us out of the human sphere and shut us up to the physical. If I can get my foot on what Brunhes calls the "humanized surface"³⁷ of our planet I am content. I shall have enough to do without quarreling with my neighbor, or resenting anything he may say to me. Brunhes also says that we are where roads meet, with facts from many sources, that we must not be a bazaar for retailing everything, but have our own domain and commit no trespasses. What the limits of this field are is not so clear, but why trouble about it, when no science has a fenced domain?

Ratzel makes a sweeping criticism of Buckle when he says that *evolution* is unspoken by him.³⁸ The great geographical philosopher of Leipzig made it forever imperative for us to "go back into the past." He speaks of differentiation, of bequeathed influences, of the migration of developed traits—he never lets you doubt that he is moving into the realm of Darwin. So the geographer, if he touches man at all and the more if he opens the question of geographic influence must be in daily contact with the principles of biological evolution, so far as the specialists have mastered them. I will not try to say how far he may supply useful data to the biologist, sure it is that human anatomy, physiology and psychology must be relied upon for light on the early (as well as late) stages of mankind. Should not this field be turned over to the anthropologist?

The first answer is that so far as environmental factors are concerned, the geographer alone is responsible for the knowledge of the total physical complex which the earth affords. But when this compre-

³⁵ W. E. Griffis, "The Japanese Nation in Evolution," 271, 386, 389-90.

³⁷ J. Brunhes, *Soot Geog. Mag.*, 29, 318.

³⁸ "Anthropogeographie," I, 97-98.

hensive survey of the physical geography has been supplied do not the geographer's duties and even his rights cease? If so and if we must leave the action of environment to the anthropologist to what kind of an anthropologist? The somatologist perhaps. The somatologist studies the natural history of the body. This is highly important but it is only one point of view. He also studies man in his physiological development but this is also partial. Your anthropologist may be primarily a psychologist a philologist or a student of early arts or of comparative religion. Or he may be an ethnologist studying the physical features mental traits linguistics practical arts legends and religions of a single tribe or people.

To which one of these will you look for a world view of the influence of environment on early or half developed man? For your answer go through all the reports and books of the anthropologists rich as they are and tell me the result. In the nature of the case the anthropologist even if he could command all the departments of his own science is not in a position to organize the principles of the influence of an earthwide environment on man. He offers indispensable materials and he may find other unities in his field but the inclusive bond of world environment belongs to the geographer.

Suppose we say that we do not need anthropologists because there are anatomists physiologists psychologists philologists and students of art and religion. The answer is that anthropology aims at the natural history of man as a whole. The specialists work indeed too often in small and isolated fields and not always with the causal and comparative principle in full view. But man the bond is there and the science receives its justification. In like manner why should there be geographers

for there are geologists meteorologists oceanographers astronomers botanists and zoologists? We say because there is no other to organize the data of all these sciences in relation to the whole earth as we see it and know it.

Taking the like case—there are anthropologists of many sorts historians of several kinds sociologists economists and technologists in ample variety. Why a human geographer? Because there is no other to exhibit the human kind (not now but in some coming day) in its causal and distributional relation to the earth and its forces viewed as a unity.

Professor Adams in his presidential address before the American Historical Association manifests a little concern because of the entrance of political science geography sociology and certain other subjects into the arena.²⁹ But history conceived on the modern scientific basis opens so vast a field that collaborating sciences may well be welcome in the task. Equally may the geographer rejoice that every science of man contributes to his own and that he in turn has something to share.

There need be no hoarding of opportunity where opportunity is infinite and no quarreling over line fences where none can exist. Professor Turner referring to economist geographer sociologist and other fellow workers has thus broadly expressed the true attitude of the historian.

The historian must so far familiarize himself with the training of his sister subjects that he can at least avail himself of their results and in some reasonable degree master the essential tools of their trade.

No one would accuse Professor Turner of advising over expansion or superficial endeavor but he seems to think it possible to be a historian and something more by virtue of which to be a better historian. So say we of the geographer. Let him be

²⁹ *Amer. Hist. Rev.* Vol. 14.

"familiar with the whole earth," as demanded by Ratzel,⁴⁰ not in detail, but broadly familiar with causal principles and their regional illustration. Then let him know the methods and results of history, or of sociology or of anthropology or of some phase of one of these. Then he can cooperate in that study of environmental influence which must be common ground for all.

All this has its bearing on the higher education for every human geographer should have his minor studies in some other science of man and no young historian should be allowed to escape who is not grounded in the principles of physical geography and who has not looked through the geographer's eye at the impress made by nature on man.

Sociology is a science which equally with geography has aroused skepticism concerning its right to be called a science. Be that as it may, its devotees occupy ground which stretches into historical territory, on the one hand, and geographical and anthropological on the other. This is conceded by Small.

The comprehensive science has the task of organizing details which may already have been studied separately by several varieties of scholars.⁴¹

The same author sets forth the influence of nature with an emphasis which if used by the geographer might call down a charge of excessive claim.

Nature sets our tasks and doles out our wages and prescribes our working hours and tells us when and how much we may play or learn or fight or pray. Life is an affair of adjusting ourselves to material matter of fact, inexorable nature.⁴²

Small does not think we yet have an adequate story of the operation of cosmic laws.

⁴⁰ "Studies in Political Areas," *Am Jour Soc*, 3, 302.

⁴¹ A. W. Small, "General Sociology," 7.

⁴² *Ibid*, 408.

in determining the course of human development.

Mr. E. C. Hayes in a paper in the *American Journal of Sociology*⁴³ discusses the relation of geography to sociology and the definition and scope of geography. He seems disposed to think that stating the effects of geographic conditions on social phenomena will be an integral part of sociology but thinks

it will still remain true that no science but geography describes the regions of the earth by bringing together into one description all the various facts separately studied by the different sciences.⁴⁴

It is fair to say that only the geographer can know the physical conditions in a broad and deep way. It is just as fair to expect the sociologist to be superior in the strictly human field. But neither can dismiss the other nor prescribe a legitimate boundary line of research. And there is always the possibility of a genius equally at home in both fields, scorning all petty frontiers of our so-called sciences, fusing and recreating the data and conclusions of lesser men, and recording for all time those large generalizations of which we dream and for which we strive.

After all that can be said on the relations of geography to other subjects, I am content to come back to a confessedly general, but safe and truthful word by James Bryce:

Geography is the point of contact between the sciences of nature taken all together and the branches of inquiry which deal with man and his institutions.

I think it is a sociologist, Ward, who likens the progress of science to the progress of a prairie fire. No doubt he means that it moves irregularly but surely. The figure is not altogether good, as indeed no figure is, for we do not move with a rush, neither

⁴³ Vol. 14, 371-407.

⁴⁴ *Ibid*, 400.

does our going leave a zone of destruction behind. Our work is constructive and slow. Whether the worker be a geographer or bear some longer name, is not material. If he have no name at all, let us accept his fact, his principle, in good faith that as workers and half thoughts come and go, the body of truth gathers volume, order and power.

We come now to the last phase of our discussion, the most important and difficult of all—lines of investigation. What is our present status? It would be a good work if some one would review historically the progress of the idea of environmental influence. Here the barest sketch must be the preliminary to our inquiry.

We may pass by the fragmental notices of ancient and medieval writers. Modern seed thoughts are not uncommon, and some harvest could be gathered from the philosophers and literary writers, Hobbes, Montesquieu, Kant, Herder, Hegel, Comte, Taine, and others. Humboldt, Ritter and Guyot laid the foundations of our modern human geography, and then came Darwin, pointing the road to fruitful study for all the sciences of organic nature and of man. Ratzel, in the spirit of Darwin kept the unfolding of geography abreast of the progress of anthropology, history and other human sciences in the last half century, and now Miss Semple has placed all geographers in her debt in the expansion and precision which she has added to the work of Ratzel.

General works of lesser scope, some of them regional, have appeared in this country and in Europe. Mackinder, Herbertson, Lyde, Chisholm, and others in Great Britain, and Vidal la Blache, Brunhes, Partsch, Penck and many others on the continent, have made important contributions. Already we have a large and rapidly growing list of small monographs dealing with limited phases or

regions in this country. In America this work is largely the achievement, direct and indirect, of the members of this association, and the present program is sharp evidence of the force of an impulse that has gathered power among us during the ten years of our cooperative endeavor.

My first hint is in the direction of climatology in its relation to man.⁴⁵ Here is a new science, with a growing body of observation, generalization and record, made available in description and in maps. Climatology is beginning to be appreciated in relation to other fields of physical geography. We begin to value and to express in text books the relation of the atmosphere to the origin of land surfaces, glaciers, aridity and the waves and currents of the sea. We see its functions also in relation to the mineral contents of the earth, and in relation to the origin and use of soil.

Even more pronounced is the growth of ideas in relating the atmosphere to fauna and flora, to plant and animal types and societies, to bacteria and to forests, steppes and deserts. Involved in all this relation to the inorganic and organic world is an immense indirect influence on man.

There is also direct influence on man, through temperature, varying constitution, variations of pressure, moisture content, movements, optical effects and sound waves. And we can not stop short of psychological, social and economic phases of influence all tangled in difficult fashion. When the consumptive goes to Colorado for help and finds it, what has accomplished the result? Is it rarity and increased lung expansion? Is dryness and a non relaxing quality uppermost? And how much is due to new hope, new effort, fresh scenery, new and glorious land forms, clear skies, gray desert and new social environment? Let

⁴⁵ J. Brunhes, *Scott. Geog. Mag.*, 29, 812, C. R. Dryer, *Jour. Geog.*, Feb., 1913, 178, Ratzel, "Anthropogeographie," I, Ch. Das Klima.

us move, but move cautiously, heeding Professor Ward's emphasis on doubtful elements in the relation of climate to disease. Perhaps there is no subject, unless it be politics, on which men say so much and know so little as about climate.

Geography has a considerable body of good knowledge of climate in relation to modes of living in typical parts of the world. We know that the Eskimo is carnivorous, the tropical savage vegetarian and that the denizen of temperate latitudes brings both foods to his table. We know the climatic results in clothing and shelter, in nomadic and pastoral agricultural and static life, and among hunters of the forest. These are all important, but more or less indirect climatic effects, so well set forth by Herbertson in "Man and His Work."

But what of direct effects of climate? I hesitate to use the word direct of such activity. Such is our ignorance of the precise efficiency of these forces, that apparent direct agents may turn out to be mediate, after all.

How much exact knowledge have we in the field of coloration? Grant that this is mainly a physiological problem, so far as man is concerned will it ever be solved, and the results broadly stated except in collaboration with geography?

Color almost certainly developed in strict relation to climate. Right away in the back ages we must place the race making epoch, when the chief bodily differences, including differences in color, arose amongst men.

This is from Marett and he adds that natural selection had a clear field with the body before mind became the chief factor in survival.

Now, how much is definite here? What is this "strict relation" to climate? And what element of climate does the work? Is it heat, or light, or moisture, or a combination of these? What does each climatic factor do, and does it do what it does,

independently, or by the aid of some non-climatic factor? Why is the Malay brown, the Chinaman yellow, the American Indian coppery and the negro black? And how do the osteological features and the facial features correlate, if at all, in origin with the color? Here is a vast field. What of assured answer, is on record?

Brinton says that climate and food supply are the main causes of the fixation of ethnic traits. He adds that temperature, humidity and other factors bear directly on the relative activity of lungs, heart, liver and skin. This seems to come near to the core of things, but no precision is reached and I suppose can not be in the present state of knowledge. Ratzel was not wrong in citing the negro's dark skin as illustration of the fact that the search for causes goes after hard and deep rooted things.

The study of the races of Europe teems with conjectures about blonde and brunette, but the physiological basis is wanting. We should like to know whether the Mediterranean longhead is a darkened Teuton or whether the Teuton is a bleached African. Here is joint work for physiologist, anthropologist and geographer.

Ward notes the fading of hair, beards and skins of polar explorers.⁴⁶ The same author, leaving open the origin of color, quotes Darwin on the accumulation of color through natural selection and contents himself with the assured fact that color, however obtained, is an advantage in a hot climate. This field therefore is almost unworked. I hesitate to say that the door for research is wide open, but one would hesitate even more to believe that the problem can not be solved.

Suppose now we leave these primitive and racial puzzles and come down to possible effects of climate that can be seen and registered in a few generations, if there be

⁴⁶ R. DeC. Ward, "Climate, Considered Especially in Relation to Man," 216.

such effects. Here is the question of acclimatization and tropical disease, in short, of the white man's burden.

Here again Ward proceeds with instructive caution. It is a complex subject, he says, conclusions are contradictory, curves may be made to show anything. There are many weather elements and there are many other factors such as sanitation, foods, water, habits, altitude, soil, race, traffic and other controls. Microorganisms intervene to make climate largely an indirect influence.⁴⁷

Thus we have a group of problems for the medical observer, but either in him or with him must the geographer share the task whose successful accomplishment affects the destinies of every colonial empire and the ultimate place of the white race. Brinton speaks of the hopelessness of the problem⁴⁸ and Ripley recognizes the importance of it by criticizing Ratzel for inadequate attention to it in the second volume of the "Anthropology."⁴⁹ We have an interesting discussion in Woodruff's "Effects of Tropical Light on White Men." It is for a more competent hand to estimate its value. Some of its generalizations seem too sweeping and too easy to be true. Altogether in this whole field, a field of high practical importance, there has been much sincere effort, but no great harvest.

We want narrower fields of investigation and better proven results. Only thus will be gathered the data for great generalizations. In this direction we may cite a passage of Hahn on the physiological effects of diminished pressure,⁵⁰ and the studies of E. G. Dexter and H. H. Clayton on the sociological effects of climate.

Let us look at the field of biogeography.

⁴⁷ "Climate," 180 et seq.

⁴⁸ D. G. Brinton, "Races and Peoples," 278-83.

in relation to man. The distribution of plants and animals as forming large elements in environment can not fail to involve man and to uncover many interesting relationships. This study is now in a hopeful state of vitality and progress. Our own association has a good number of workers in this field.

A wealth of pertinent facts awaits discovery and coordination as regards the coincident distribution of man with plants and animals. Payne, in the history of early America already cited, uses this as a basal principle showing the migration and presence of organic forms in causal relation to man. Here again Ripley finds occasion to criticize Ratzel for insufficient attention to the theme. A few suggestive illustrations may be given. Kirchhoff in his "Man and Earth"⁵¹ coordinates the Mediterranean spread of the Phœnicians with the occurrence of the dye-yielding mollusc. Dr. C. Hart Merriam once surprised the writer by saying that the beaver was the most important fact in early American history. The more one considers this the less one is disposed to consider it as an outburst of a biologist's enthusiasm.

In Hansa days tens of thousands of people dwelt in the Peninsula of Schonen, in the towns of Falsterbo and Skanor, at the most southwestern tip of Sweden. To day an old church, a few cottages and a summer hotel make up Falsterbo, while Skanor is a sleepy village of a few hundred people. Why should this throbbing Baltic market of centuries ago have suddenly declined to insignificant shore villages? Because the herring migrated to other waters. A new harbor has been built at Skanor and it will be seen whether modern conditions can restore the prosperity which the runaway fish destroyed.

Dr. Scharfetter in a work on the dis-

⁵¹ Trans. of "Mensch und Erde," 30-31.

tribution of plants and man sets the Roman boundary in Germany at the edge of the Franconian forest and cites the fact that the Arabs went wherever the date palm would grow.⁵² The practical biologist such as the agricultural explorer, turns the problem around, shows how to control the distribution of lower life and thus to modify the distribution of man.

Such results must flow from the work of the department of botanical research of the Carnegie Institution, and Dr McDougal of the Desert Laboratory well sets forth the interrelations of the sciences when he likens the work to the making of a cantilever bridge whose further ends may rest on chemical, physical, geological or geographical piers.⁵³ A good illustration of this finds immediate place in the investigations by Professor Huntington, in western forests of climatic events.

The climatologist asks for definite climatic effects on man. The ethnologist or sociologist finds traits in man which might have a climatic origin. The geographer wants all that all types of specialists can give him, both in the physical and psychical spheres. Thus we may approach from the point of view of causes or of results and follow down or up the stream of effects.

We have made a hasty survey of two fields of causation, the one physical, the other organic. Let us turn to certain groups of phenomena in the realm of effects or results. The most important and surely the most baffling problems here are in the psychic field. Here the geographer will be peculiarly dependent on workers in sister sciences and the gap may be hard to bridge. Geographers are not as a rule specialists in psychology, and there is no reason to believe that many students in psychic fields are specially versed in geography. If we

can offer a stimulus which shall lead these kinds of scholars to struggle up the stream of causality, it may be safer than for us to drift down through rapids and among rocks. But the work ought to be done and the geographer can at least show its worth and encourage the doing of it.

In this research we are not to think that the earth was all powerful with early man, but is helpless to day. Color or other race features may have been fixed, but this is not all. If there is something in man that is found in every man, wherever he is, he is not thereby released from the pressure of environment. Psychic reaction on nature does not destroy nature's efficiency but in a degree directs, refines and uses it. When Professor Lester F. Ward says that "the environment transforms the animal, while man transforms the environment,"⁵⁴ he utters but a partial truth. Perhaps he was attracted by rhetorical form for in a later passage he recovers himself recognizing the psychic effects of environment, for,

Courage, love of liberty, industry and thrift, ingenuity and intelligence, are all developed by contact with restraining influences adapted to stimulating them and not so severe as to check their growth.⁵⁵

If a hard winter is a "great Teutonic institution" if rains, dark skies and winter have made more serious peoples in the north of Europe than are found along the Mediterranean, if Geikie rightly ascribes the heart of Ossian's poems to nature in the West Highlands,⁵⁶ these qualities of environment are pressing on the human spirit to day as in Neolithic or Celtic time, moderated perhaps, by modern skill in getting protection from nature and by greater contact with all the world. We will not deny the assertion of Thomas that "the force of climate and geography is greater in the

⁵² Paper is noticed, *Scott. Geog. Mag.*, Vol. 27, 39-41.

⁵³ *An. Rep. of Director*, 1912.

⁵⁵ *Ibid.*, 58.

⁵⁶ A. Geikie, "Scenery of Scotland," 407-08.

lower stages of culture and that ideas play an increasing rôle" but we do not know on what ground he makes the further claim that the peculiar cultures of Japan, China and India were in the first place the results of psychic rather than geographic factors.⁸⁷

There is a beautiful passage in Ratzel which I now commend to those historical and sociological philosophers who think that psychic qualities and powers are released from environmental influence. If ethnographers utter the view that the development of culture consists in ever wider release from nature we may emphasize that the difference between nature and culture folk is to be sought not in degree but in the kind of this connection (*Zusammenhang*) with nature. Culture is freedom from nature not in the sense of complete release but in that of much wider union. The farmer who gathers his corn in the barn is really as dependent on his ground as the Indian who harvests in swamps wild rice which he did not sow.

We do not on the whole become freer from nature while we deeply exploit and study it, we only make ourselves in single cases independent of it, while we multiply the bonds.

Not to do Ratzel injustice it is he who has also called "the spirit of man a completely new phenomenon upon our planet," and has asserted that

No other being (*Wesen*) has worked so permanently and upon so many other existences as man, who has profoundly changed the living face of the earth.

We are to interpret cautiously similar human phenomena in different parts of the world. We can not here follow the evolutionary axiom that if a species of trilobite is found in England and in New York, there has been one point of origin and a migration. The same things appear in

⁸⁷ W. I. Thomas, "Source Book for Social Origins," 180-81.

many places either through the unity of the human spirit or the likeness of environments or from both causes. This is stated by Fewkes.

Identity in the working of the human mind is recognized by all anthropologists and the tendency to ascribe cultural identities to contact or migration is much less prevalent now than formerly.⁸⁸

In like manner Boas shows that some ideas are so general that they could not have been diffused historically through migration and contact but must have arisen independently in different places.⁸⁹

Tylor is no less emphatic.

Researches undertaken all over the globe have shown the necessity of abandoning the old theory that a similarity of customs and superstitions of arts and crafts justifies the assumption of a remote relationship if not an identity of origin between races. There has been an inherent tendency in man allowing for difference of climate and natural surroundings to develop culture by the same stages and in the same way.

Citing the pyramid building of Aztec and Egyptian,

Each race developed the idea of a pyramid tomb through that psychological similarity which is as much a characteristic of the species man as his physique.⁹⁰

We leave this topic with the single suggestion that in the psychic field, a useful and difficult piece of research is open to the student of comparative religions, who is at the same time interested in anthropogeographic problems and has the needed geographic training. How far the essential content of religious aspiration and thought, as well as the ritual of worship has been influenced by environment, has, I think, never been shown in any full synthetic

⁸⁸ J. W. Fewkes, "Climate and Cult," 8th Inter Geog. Cong., 670.

⁸⁹ F. Boas, "The Mind of Primitive Man," 151-64.

⁹⁰ E. B. Tylor, *Ency. Brit.*, Art. "Anthropology."

way It is a task of no common difficulty, not to be lightly undertaken, but worth the doing

Another field of effects, much more accessible to the pure geographer is the distribution of population studied in the causal way Enough practise in statistical method for this inquiry can be readily acquired and the results should be most fruitful Jefferson's recent papers have been suggestive in this field of research, which involves in intimate combinations, physical, economic racial and social conditions Akin to this study is the classification of towns and cities, developing the principles of origin, growth and differentiation, as in a recent valuable paper of Chisholm The city as a geographic organism may be freely taken as an inexhaustible theme

Another great sphere lies in regional studies such as states, physiographic units, and countries The number of such studies, maturely developed now available may perhaps be counted on the fingers of one's hands The aim should be not alone directed upon the more obvious matters of route and industry, but also upon deep and underlying principles What rich and alluring subjects for the intensive student would the state of Pennsylvania offer, of Kentucky, Minnesota or California! Who will develop for us our coastal plain or piedmont, treating town sites, roads, soils, crops, industries, racial composition and social status? Who will do a like work for the great Appalachian Valley, that magnificent and little understood unit of our east—its trails and roads, its agriculture, towns, migrations and historical significance in colonial and current life? There is room for more such studies as those of Whitbeck upon glacial and nonglacial Wisconsin and of von Engel on the effects of

glaciation upon agriculture⁵¹ The latter, indeed, is not regional except as it naturally deals largely with principles as illustrated in our own country

Will Mr Mackinder, or some one else, take up Great Britain, omitting the purely descriptive, as he could not in Britain and British seas properly do and discuss more fully questions of geographic influence as regards agricultural distribution the localization of industries, the distribution of population in general, and the effect of various factors such as insularity, climate and world position in the development of British character British political unity, and British social conditions

Or in the United States there are racial compositions, new physical environments, offering new social and economic conditions to population groups as seen in comparison with conditions in the parent lands of Europe Finally there are innumerable beckoning fields of a small and local sort, out of whose diligent study general principles will rise and become established

Our goal is broad generalization But the formulation of general laws is difficult and the results insecure until we have a body of concrete and detailed observations Quoting Brunhes,

We must then make up our minds to put aside generalities and vague analogies between nature and man We must make it our business to search for facts of interaction⁵²

From Boas also,

It goes without saying that haphazard application of unproven though possible theories will not serve as proof of the effectiveness of selection or environment in modifying types⁵³

Detailed investigation of single problems, in small and seemingly unimportant

⁵¹ O D von Engel, "Effects of Continental Glaciation on Agriculture," *Bull Am Geog Soc*, XLVI, 241-64, 336-55

⁵² J Brunhes, *Scott Geog Mag*, 29, 311

⁵³ F Boas, "The Mind of Primitive Man," 51

fields, must for a long time prepare the way for the formulation of richer and more fundamental conclusions and general principles than we have yet been able to achieve. We should not wait for some one to state or demonstrate these laws. This is yet, even for a genius impossible. We must contribute in partial, microscopic, sometimes unconscious ways to the emergence of such laws.

Professor Adams speaking of the available and most useful tasks of the historian, has a word which is equally good for us,

To furnish materials, to do preliminary work, is to make a better contribution to the final science than to yield to the allurements of speculation to endeavor to discover in the present state of our knowledge the forces that control society, or to formulate the laws of their action⁴⁴

Not only is this a model principle but it emphasizes the value of our goal, for the real philosophy of history will not be written until geographic factors have had broader and deeper recognition. Here I do not speak as a geographic enthusiast, nor in denial of the supremacy of the human spirit.

Such then is the mode of advance of our science—the old story of interest, hypothesis, test, correction, publication, criticism, revision, progress by error, by half truth, by zigzag, spiral and apparent retrograde, by aero flight by patient tunneling, some at the salients of progress, and some in the ranks of humble endeavor, the goal in front of all.

ALFRED PERRY BRIGHAM

COLGATE UNIVERSITY

LEWIS LINDSEY DYCHE

LEWIS LINDSEY DYCHE, professor of systematic zoology and curator of the collections of mammals, birds and fishes, at the University of Kansas died in Topeka, Kansas, Wednesday, January 20, 1915. Professor Dyche

was intimately associated with the life of the university for nearly thirty eight years, having seen nearly every class graduated from the institution. His first connection with it was as a student in the preparatory department. He entered the middle class of the preparatory department in September, 1877, at the age of twenty years being registered from Auburn, Kansas. James Marvin was then chancellor of the university. There were 12 members of the faculty and a total attendance of students of 361 of whom 110 were of college grade. Mr. Dyche finished the senior preparatory work at the end of the next year and in September 1879 became a freshman in the collegiate department enrolling as a student in the classical course. In the year 1880, however, on entering his sophomore year, he changed his work to that of natural history. He became a junior in the collegiate department in the regular course of events in September, 1881, still enrolled in his newly chosen field of natural history.

In 1882 Mr. Dyche was made instructor in natural history but retaining his place in the junior class. He continued his connection with the instructional side of the university until his death. Mr. Dyche was graduated from the university in June, 1884, receiving two degrees that of Bachelor of Arts and that of Bachelor of Sciences, he having combined both the classical and scientific work then offered in the university. He continued his study in natural history at the university of Kansas by entering the postgraduate course in September 1884 receiving his Master of Arts degree in 1886 and his Master of Science degree in 1888. His teaching title was during these years "assistant," being equivalent to the title of assistant professor at the present time.

In September, 1888, he was advanced from the rank of assistant in natural history to that of full professor of anatomy and physiology, taxidermist and curator of mammals, birds and fishes. In 1890 zoology was added to his list of teaching subjects. We must remember, however, that in the nineties the number of both students and teachers was small and

⁴⁴ Geo. B. Adams, *Am. Hist. Rev.*, 14, 236

the field of work had not been so carefully differentiated as at present. In September 1892 physiology and anatomy were dropped from his title and he limited himself to the field which he occupied with little change until the end of his career. His title became professor of zoology, taxidermist and curator of mammals and birds. Francis H. Snow was then chancellor of the university.

It stood thus until 1899 when anatomy for a year was again put in his charge and his title of curator was that of curator of zoological collections. In the very next year we find anatomy cared for in a separate department and Professor Dyche returning to his work under the title of professor of systematic zoology and taxidermist. In 1903 the title of taxidermist was dropped as being unnecessary and Professor Dyche was given the title which he retained until his death, namely that of professor of systematic zoology and curator of mammals, birds and fishes. In 1901 the legislature of the state largely through the efforts of Professor Dyche appropriated \$75,000 for the erection of a natural history museum for the housing of the natural history collections. The building was finished in 1902, a considerable part of it being given over to the extensive and important collection of North American mammals and birds.

On December 1, 1900, Professor Dyche was given partial leave of absence in order that he might act as fish and game warden for the state of Kansas. This action was taken by the board of regents of the university at the request of the then governor, W. R. Stubbs. This request was acceded to for the reason that of all men in the state of Kansas Professor Dyche was the most competent in every way to carry on a large project of this character on a scientific basis. It was acceded to also with the belief which has been fully substantiated that the fish hatchery under his supervision could be put upon an economic and scientific foundation.

Since December 1909 Professor Dyche has given most of his time to the fish and game wardenship although still connected with the

university as professor of systematic zoology and curator of mammals, birds and fishes. For some years prior to 1900 Professor Dyche had done little or no undergraduate class work, confining himself to work as curator, investigator and writer and to such occasional graduate work as was desired by students expecting to enter the museum field.

During his long career as a teacher in connection with other university men he took part in or conducted many scientific expeditions, twenty-three in all. It is said for the collection of museum material. These expeditions covered practically all of North America. Some of the most important were to Greenland and the Arctic regions. Of the Peary expedition and the rest it is not for me to speak. They were filled with strenuous endeavor and many thrilling experiences. Indeed few men even of bygone border times could equal his experiences in this respect. He was a noted hunter and won his place as an explorer, his talents as naturalist, woodsman, hunter and explorer being of a high order. The result of all of this was no doubt to shorten his days but he helped build up large scientific collections of great value into which he had put his life and he saw them become an integral part of the university which he loved. He was one of the charter members of the chapter of Sigma Xi at the University of Kansas. He lectured much and in this field was exceedingly graphic and interesting. He wrote much, his last writings being in the shape of bulletins in regard to fish culture in the large. These bulletins are much sought after and show the results of a life time of close observation and study. As a taxidermist he had few equals, his knowledge of the pose and habits of animals and the habitat in which they live being unusually accurate. His fidelity to nature, his great skill and his keen observation are well attested by the brilliant display of North American mammals which he was largely instrumental in preparing at the University of Kansas.

Professor Dyche had in larger degree than most men the creative instinct, the instinct

of originality. He had immense persistence and enthusiasm, well attested by his accomplishments against great odds. A mere study of his life is in itself thrilling. He leaves an honored name of which his family may well be proud. He was an extremely likeable man, a loyal son of his university who brought much honor to his alma mater.

FRANK STRONG

UNIVERSITY OF KANSAS

THE BONAPARTE FUND OF THE PARIS ACADEMY OF SCIENCES

THE committee appointed to deal with the allocation of the Bonaparte Fund for the year 1914 has, we learn from *Nature*, made the following proposals, which have been unanimously adopted by the academy.

1 2,000 francs to Pierre Broteau, to enable him to pursue his researches on the use of palladium in analysis and in organic chemistry.

2 2,000 francs to M. Chatton, to give him the means of continuing his researches on the parasitic Peridiniums.

3 3,000 francs to Fr. Croze to enable him to continue his work on the Zeeman phenomenon in band and line spectra, the amount to be applied to the purchase of a large concave grating and a 16 cm. objective.

4 6,000 francs to Dr. Heimsalech, for the purchase of a resonance transformer and a battery of condensers for use in his spectroscopic researches.

5 2,000 francs to P. Lale, director of the Vatican Observatory, to assist in the publication of the photographic map of the sky.

6 2,000 francs to M. Pellegrin, to facilitate the pursuit of his researches and the continuation of his publications concerning African fishes.

7 2,000 francs to Dr. Trouset, to aid him in his studies relating to the theory of the minor planets.

8 2,000 francs to M. Vigouroux, to assist him in continuing his researches on silicon and its different varieties. These researches, in which it is necessary to make use of hydrofluoric acid, necessitate the use of expensive receivers.

9 3,000 francs to M. Alluaud, for continuing the publication, undertaken with Dr. R. Jeannel, of the scientific results of three expeditions in eastern and central Africa.

10 9,000 francs to be divided equally between

MM. Pitard, de Gironecourt and Leconte, all members of the scientific expedition to Morocco organized by the Société de Géographie.

11 2,000 francs to Professor Vasseur, to assist him in his geological excavations in a fossil bearing stratum at Lot et Garonne.

12 3,500 francs to Dr. Mauguin for the continuation of his researches on liquid crystals and the remarkable orientation phenomena presented by these singular bodies when placed in a magnetic field. The grant will be applied to the construction of a powerful electromagnet.

13 2,000 francs to Dr. Anthony to meet the cost of his researches on the determinism of the morphological characters and the action of primary factors on the course of evolution.

14 4,000 francs to Professor Andoyer a first instalment towards the cost of the calculation of a new table of fifteen figure logarithms.

15 4,000 francs to M. Bénard to enable him to continue his researches in experimental hydrodynamics on a large scale.

16 2,000 francs to Dr. Chauvenet to enable him to continue his researches on zirconium and its complex combinations.

17 2,000 francs to Professor François Franck, for the chronographic study of the development of the embryo, with special examination of the rhythmic function of the heart.

18 2,000 francs to Professor Sauvageau for the pursuit of his studies on the marine algae.

SCIENTIFIC NOTES AND NEWS

THE gold medal of the Royal Astronomical Society has been conferred on Professor A. Fowler for his work in astrophysics.

THE Berlin Anthropological Society has awarded its Rudolf Virchow Medal to Dr. Karl Poldt, emeritus professor of anatomy in Vienna.

PROFESSOR FRITZ HABER and Professor R. Willstätter both of the Kaiser Wilhelm Institute for Chemistry, have been elected members of the Berlin Academy of Sciences.

DR. HANS MEYER known for his explorations in Africa has been elected honorary professor of colonial geography in the University of Leipzig.

DR. PIERRE WEISS, professor of physics in the Zurich Technical School, has been awarded

the Lasferre prize (\$1,600) by the French Institute

DR JOSEF ENGLISH, emeritus professor of surgery in the University of Vienna, has celebrated his eightieth birthday

DR ALFRED KLEINER, professor of physics at Zurich, has on account of the state of his health retired from his chair and has been made honorary professor

MR T F BURTON has succeeded Mr Watson Smith as editor of the Journal of the Society of Chemical Industry, which is issued fortnightly in London by the society

PROFESSOR G C BOURNE, Linacre professor of comparative anatomy at Oxford, has been given leave of absence to engaged in military service

WE learn from *Nature* that the second Indian Science Congress, organized by the Asiatic Society of Bengal, was held at the Presidency College, Madras, on January 14-16, under the presidency of Surgeon General W B Bannerman. The sections of the congress, and their chairmen, were as follows: Agriculture and applied science, Dr H H Mann; physics, Mr C V Raman; chemistry, Professor P C Ray; zoology, Dr N Annandale; botany, Dr O A Barber; ethnology, Mr H V Nanjundayya; geology, Dr W F Smeeth.

PROFESSOR R W THATCHER, chief of the division of agricultural chemistry of the University of Minnesota, has been elected president of the Minnesota Section of the American Chemical Society. The section will hereafter hold regular meetings on the third Friday evening of each month at various laboratories in the Twin Cities.

DR A F GILMAN, head of the chemistry department of Ripon College, has returned for the second semester's work after a leave of absence for a half year spent in study and travel.

PROFESSOR JOHN DEWEY delivered the eighth series of McNair lectures at the University of North Carolina on February 5, 6 and 7. His subject was "Philosophy and Politics." The lectures dealt with (1) The Inner and Outer

Worlds, (2) The State and Moral Life, (3) The German Philosophy of History.

DR C WARDELL STILES, of the U S Public Health Service, gave the ninth Weir Mitchell lecture of the College of Physicians, Philadelphia, on February 16. His topic was "An Experiment from the Standpoint of Applied Zoology in Medical Inspection of Schoolchildren as a Basis for an Intensive Public Health Campaign."

DR LILIAN WELSH, professor of physiology and hygiene at Goucher College, Baltimore, spoke on February 12 at Mt Holyoke College on "American Women in Science." The lecture was given under the auspices of the Nettie Maria Stevens memorial lectureship fund, established by the Naples Table Association, for promoting laboratory research for women. The lecture was also given during the week at Wellesley College and Brown University.

PROFESSOR DOUGLAS W JOHNSON, of Columbia University, lectured before the Engineers Club of Trenton, N J, on February 11, on

"The Topography of Western Europe and its Influence on the Campaign against France." On January 15 he delivered the same lecture before the Geographical Society of Philadelphia.

PROFESSOR ARTHUR H BLANCHARD, of Columbia University, on February 9 delivered an illustrated address on the subject "Economic Phases of Highway Engineering" before the Middletown Scientific Association at its meeting at Wesleyan University. On February 11 he delivered an address on "The Highway Engineer in Public Life" at the annual meeting of the Engineers Society of Northwestern Pennsylvania.

THE Illinois State Museum of Natural History announces a course of four popular illustrated lectures on natural history on Friday evenings as follows:

February 19—"Volcanic Emanations," by A L Day, PhD, director Geophysical Laboratory, Washington, D C.

February 26—"The Wonderful Heavens," by F B Moulton, PhD, professor of astronomy, University of Chicago, Chicago.

March 5—"The Trophies of the Fossil Hunter," by A. R. Crook, Ph.D., curator Illinois State Museum, Springfield.

March 12—"Alaska Salmon" by H. B. Ward, Ph.D., professor of zoology, University of Illinois, Urbana.

THE University of Oxford has received \$2,200, as we learn from *Nature* from friends of the late Professor Gotch, with the view of perpetuating the memory of the late Wayne flete professor and of encouraging the study of physiology within the university. The income of the fund will be applied, first, to the establishment of a Gotch memorial prize to be awarded annually after examination, to a student in the physiological laboratory, and secondly to the creation and maintenance of a Gotch memorial library in the same laboratory. A portrait of Professor Gotch has been hung on the walls of the department.

SAMUEL WALKER SHATTUCK, for forty-four years professor and comptroller of the University of Illinois, died at his home in Champaign on February 13. Professor Shattuck was born in 1841 at Groton, Mass. Since 1868 he has served the University of Illinois. For thirty-seven years he was head of the department of mathematics and from 1873 to 1912 he looked after the business affairs of the university. In 1912 Professor Shattuck was retired on the Carnegie Foundation.

MR. F. W. RUDLER, curator of the Museum of Practical Geology, London, died on January 23.

DR. KARL LUDWIG MOLL, formerly professor of mechanical engineering in the Riga School of Technology, has died at the age of eighty-three years.

DR. NICHOLAS OUMOFF, professor of physics at Moscow, has died at the age of sixty-eight years.

THERE have been killed in the war M. Robert Douville, paleontologist in the Paris School of Mines, Dr. Anton Lackner, docent for geometry in the Vienna Technological Institute, Dr. Rudolf Rau, formerly professor of physics at Jena, and Dr. Felix Hahn, geologist of the University of Munich.

THE Berlin correspondent of the *Journal* of the American Medical Association writes that according to the latest official list, 132 medical men have so far been killed in the war, 22 wounded, 45 have died and 166 are missing or prisoners. Among the medical victims of the war are three distinguished scientific men, Professor Jochmann, the medical head of the infectious department of the municipal Rudolph Virchow Hospital, succumbed to typhus fever which he acquired in the examination and treatment of Russian prisoners of whom 900 are ill with typhus. Professor Sprengel, the superintendent of the surgical department of the Ducal Hospital in Brunswick, died from sepsis at the age of sixty-two having infected himself at an operation on a wounded soldier. The Freiburg dermatologist Professor Jakobi, died in the field as a result of disease.

THE U. S. Civil Service Commission announces an examination for assistant in agricultural geography for men only to fill a vacancy in this position in the Office of Farm Management, Bureau of Plant Industry, Department of Agriculture, Washington, D. C., at a salary ranging from \$1,800 to \$2,000 a year. The duties of this position will be to assist in investigations being carried on in the above office concerning the development of agricultural enterprises under the influence of geographic conditions such as topography, climate, soil, location, etc.

THE Robert D. Brigham Hospital for incurables benefits to the extent of \$50,000 by the will of Mrs. Ellen A. R. Goldthwait of Boston. This sum is to constitute a fund to be known as the Joel and Ellen Goldthwait Research Fund and the income is to be used for work to increase the knowledge of chronic diseases.

It is stated in *Nature* that a meeting of the General Organizing Committee for the International Botanical Congress, which has been arranged to be held in London next May, took place at the Linnean Society's rooms on January 21. A report was given of the work of preparation which had already been carried out by the executive committee, and the mem-

bers were asked to consider the present position. The two following resolutions were carried: (1) That the congress be not held in 1915, (2) that the present executive committee continue to act so long as necessary. The committee was strongly of opinion that a meeting of the congress in London should not be abandoned and the suggestion was made that it might take place at the next quinquennium in 1920. But it was agreed that nothing definite could be settled at the present time and the following resolution was passed: 'That the executive committee be authorized to convoke a meeting of the general committee at some future date to consider the date of the congress.' It was also decided that in the meantime the general committee be called together once a year.

THE year 1914 was an eventful one in the industry of mining radium, uranium and vanadium ores and had by far the largest year's production yet made. Figures collected by Frank L. Hess of the United States Geological Survey indicate that the output amounted to about 4,300 short tons of dry ore carrying 87 tons of uranium oxide and 22.4 grams of metallic radium. The ore was valued at about \$445,000. The ore produced in 1913 contained 41 tons of uranium oxide and 10.5 grams of radium and that produced in 1912 contained 28 tons of uranium oxide and 6.7 grams of radium. About nine tenths of the contained radium is thought to be recoverable under unproved processes. Although carnotite, a mineral of these rare metals, contains three times as much uranium oxide as vanadium oxide, the Colorado and Utah ores of these metals generally contain other vanadium minerals in such quantity that vanadium oxide is present in excess of the uranium oxide. However, little is paid for the vanadium as its separation from uranium is troublesome and only a few thousand dollars was received in 1914 by brokers or producers for the vanadium in the ores sold. Sandstone impregnated with roscoelite, a vanadium-bearing mica, is mined at Vanadium, San Miguel County, Colo., on the eastern edge of the carnotite field, by the Primus Chemical Co.

The total quantity of vanadium in the carnotite and other ores mined during the year was apparently about 432 tons. About the beginning of 1914, owing to the very high prices charged for radium salts, their scarcity, their evident usefulness in treating diseases, the practical impossibility of the poor receiving treatment by radium because of its scarcity and high cost, and to the fact that much of the radium-bearing ore was being shipped out of the country, Secretary of the Interior Lane caused to be introduced in Congress bills reserving radium-bearing lands from entry as mining claims and providing for government purchase. The bills are still pending. During the year the National Radium Institute conducted under the supervision of the Bureau of Mines mining operations at Long Park near Paradox Valley in Montrose County, Colo., and a plant at Denver for the production of radium and investigation of processes. The work has been so encouraging that Director Holmes has announced the probable production of radium at one third its present cost. Messrs. Lind and Whittmore of the Bureau of Mines state that their investigations show that carnotite carries proportionally to its content of uranium as much radium as pitchblende or other uranium minerals—that is, the radium has reached its maximum ratio to the uranium from which it is derived and is thus in equilibrium. From published results of experiments made on casual specimens of carnotite it had been popularly supposed that carnotite was less rich than pitchblende in radium.

AN unusual feature of the work of the United States Coast and Geodetic Survey, Department of Commerce, during the past summer was the successful use of a one and one-half ton automobile truck in transporting an astronomical party and outfit through a portion of the southwest which is generally dreaded by the transcontinental tourist. The party was in charge of Mr. O. V. Hodgson and was in the field from May to October. The trip is the more remarkable when the fact is taken into consideration that the requirements of the work prevented a close adherence to the routes usually followed. Observations were

frequently made on mountain peaks, so the journey was from mountain to mountain, rather than along main traveled roads from city to city. The general route followed by Mr. Hodgson and his party was from Denver, Colorado, to Pecos, Texas, then southwest almost to El Paso where a detour was made over poor trails through southern New Mexico into Arizona. The central and southern portions of the latter state were rather well covered, the itinerary including Solomonsville, Douglas, Benson, Tucson, Globe, Phoenix, Yuma and Parker. The auto truck was then driven across California to San Diego and the San Jacinto mountains, thence via Los Angeles, Mojave and Sacramento to Carson City, Nevada. Astronomical observations were carried along the California-Nevada boundary to Needles, California, where the season ended. During the season the truck, carrying a capacity load, was run more than 5,000 miles under road conditions varying from the deep mud encountered in New Mexico and Texas, and the heavy sands of the Colorado River and Nevada desert regions, to the splendid roads of southern and central California. The cost sheets of the season show that the work was done at a saving of at least 35 per cent from the cost had teams been used. The cost per mile for oil and gas varied from 27 cents to 66 cents in different sections of the country, and averaged 39 cents for the entire season. A remarkable feature of the performance of the truck and a tribute to the good work of the driver was the fact that, from the time of leaving Colorado Springs to the end of the season, about six months, during which the truck was run over 5,000 miles, only two hours were lost on the road on account of engine troubles.

We learn from the *Geographical Journal* that Messrs Geo. Philip and Son, Ltd., have prepared a relief model map of Central Europe, constructed to illustrate the topography of the main theaters of the present war. The model, which costs £8, 6s, measures 62 by 35 inches, and is on a horizontal scale of 18 miles to the inch, and a vertical one of 5,000 feet to the inch, so that the heights are exaggerated

nineteen times. Political boundaries are shown, and also towns in red, but neither roads nor railways. The model is said to show well the continuity of the Central Plain from Russia westwards to the margin of the North Sea and the Channel, and thus makes clear at once the exposed frontier of Germany, and the military reason for the violation of Belgian neutrality. Most of the places which have become famous in the western war area are marked, and it is possible to follow very clearly the battle lines of the Marne and of the Aisne, the fighting in the Argonne region, the conflicts round Ypres and the Yser, and so on. Among minor features which are well shown, are the position of the gap of Toul, due to the fact that a stream which once ran into the Meuse has been captured by the Moselle, and the deserted valley forms an open groove between the two rivers, a groove through which passes the railway from Paris to Toul and Nancy. The position of Reims, also, placed as it is on a natural line of communication between Champagne, Burgundy, the middle Rhine valley and the Low Countries, is clearly seen, and it helps to explain the constant bombardment of that ill-fated city, whose splendid cathedral illustrates its early importance as a crossing point of routes.

We learn from the *Journal of the American Medical Association* that the secretary of state of Missouri has issued articles of incorporation to "The Missouri Foundation for Health Conservation," the purposes of which are "the conservation of health and the prevention of disease to the end that human efficiency may be increased and human suffering prevented." Its purposes are to be secured by any means "that demands of time or of science may require." The first activity undertaken will be a medical laboratory to be established at St. Joseph, with its tributary population of \$1,000,000. It is intended that this institution shall be a clearing house where all doctors living in the country tributary to St. Joseph may send specimens from patients for analysis and get prompt returns. The work will be financed by fees, donations, subscriptions and bequests, its aims being

scientific, social and benevolent and not commercial. In addition to the medical laboratory, other activities for health conservation will be inaugurated. The secretary of the foundation is Dr Daniel Morton, St Joseph, and the members of the board of control are prominent citizens of St Joseph and the state.

FROM the annual statement of the British board of trade *Nature* prints figures for 1913 of imports of scientific instruments and apparatus as follows:

Scientific Instruments and Apparatus (other than Electrical) Complete

Total imports	£ 710 341
Of which from Germany	362 891
Belgium	23,939
France	108,040
Switzerland	19 872
U S A	182 293

Parts thereof (including Kinematograph Films, Photographic Plates and Films, and Sensitized Photographic Paper)

Total imports	£ 2 373 426
Of which from Germany	310 229
Belgium	126 725
France	522 682
Switzerland	28 762
Italy	121,842
U S A	1,256 311

It thus appears that the imports from the United States exceed those from France and Germany combined. It may be expected that hereafter the imports of scientific apparatus (of which, however, photographic supplies are a considerable part) from the United States will exceed those from all other countries combined.

UNIVERSITY AND EDUCATIONAL NEWS

THE Thomas W Evans Museum and Dental Institute, School of Dentistry, the University of Pennsylvania, will be dedicated on February 22 and 23. On the afternoon of February 22 the presentation and formal opening of the building will take place and addresses will be made as follows:

Dr Charles Gordon, of Paris, France

Dr Wilhelm Dieck, of Berlin, Germany

Mr John Howard Mummey, M R C S, L D S, of London, England.

Dr William Simon, of the Baltimore College of Dental Surgery

Dr Edward C Kirk, dean of the Thomas W Evans Museum and Dental Institute School of Dentistry, University of Pennsylvania

THE new building of the Mellon Institute of Industrial Research of the University of Pittsburgh will be dedicated on the morning of February 26. The principal address will be made by Dr Rossiter W Raymond. In the evening Professor John J Abel, of Johns Hopkins University will deliver the first Mellon Lecture under the auspices of the Society for Biological Research of the University of Pittsburgh. The subject of the lecture will be "Experimental and Chemical Studies of the Blood and Their Bearing on Medicine."

DR KARL T COMPTON, instructor in physics at Reed College, Portland, Oregon, will go to Princeton University next fall as assistant professor of physics. Dr Compton received the degree of Ph D at Princeton in 1912.

Two new members have been recently added to the faculty of the New York State College of Forestry. Mr G A Gutches, formerly in the U S National Forest Service, later district forest inspector of Saskatchewan, Canada, becomes director of the New York State Ranger School at Wanakena, N Y. Mr H H Tryon, formerly forest engineer, becomes instructor in forest utilization. This makes eight new appointments to the faculty of the New York State College of Forestry within the past year. The appointment of Dr O C Adams as assistant professor of forest zoology was noted in *SCIENCE* of June, 1914. The other recent appointments are as follows: Dr J Fred Baker formerly professor of forestry in Michigan Agricultural College, as professor of experimental forestry, Dr L H Pennington, formerly associate professor of botany in Syracuse University, as professor of forest pathology, Dr H P Brown, formerly instructor at Cornell, as assistant professor in forest botany, Mr Shirley W Allen, formerly deputy forest supervisor of the Lassen National Forest, California, as assistant professor of

forest extension, and Mr L. D. Cox, formerly landscape architect to the Park Commission of Los Angeles, as assistant professor of landscape engineering.

SIR HENRY MIFRS, formerly professor of mineralogy at Oxford, has resigned the principalship of the University of London to become vice-chancellor of Manchester University.

MR L. G. OWEN has been appointed professor of mathematics at the Government College, Rangoon.

DR. RUDOLF HOBLER has been made professor of physiology at Kiel in succession to Professor A. Bethe, who has accepted a call to Frankfurt.

DISCUSSION AND CORRESPONDENCE

A TYPICAL CASE

PROFESSOR — graduated at — University and taking a postgraduate course received the degree of Ph.D. He then went abroad, studied at the — University, and returned to America full of enthusiasm for original research. He had published an important memoir for a thesis, which was well received; his instructors encouraged him and his fellow students appreciated and were interested in his work.

He now received an offer of a professorship in a small country college, married, and began his new life expecting to continue his investigations. He soon found that his entire time was occupied in teaching and that he was obliged to eke out his small salary by writing and lecturing. He could not bear to abandon his great object, the advancement of human knowledge, and found that he could, by extra efforts, devote a portion of his evenings to research amounting to a fourth of his entire working capacity. He went to the president of the college, asking for an appropriation for an assistant, who could do the routine work of copying, computing, etc., as well and as rapidly as he could himself. In stead of a quarter of his time, he would thus have one and a quarter, or five times as much, and could make rapid progress at small ex-

pense. The president told him that the object of the institution was teaching, not research, and that it was impossible to grant his request. A fellowship was, however, vacant, and might answer his purpose. This, however, would be of no use to him, as the fellow would not want to do routine work, but to undertake a research of his own, and would expect to be taught how to do it. His associates were teachers, not investigators, and took no interest in his plans. After repeated trials and discouragements, he abandoned his efforts and settled down as a teacher only, with no ambitions beyond enabling his classes to pass their examinations.

While good teachers are as much needed as investigators, the work of the latter may be greatly impeded if their main energy is devoted to instruction. The finding of such men and enabling them to carry on the great work for which they are fitted, by providing them with apparatus, assistants, or means for publication, is one of the principal objects of the Committee of One Hundred on Scientific Research.

EDWARD C. PICKERING

January 27, 1915

A SPHENOIDAL SINUS IN THE DINOSAURS

THE work which has been done recently on the accessory nasal sinuses in man and the mammals by H. W. Loeb, J. P. Schaeffer, Onodi, Ernst, Witt, Ritter, A. W. Meyer, as well as the earlier work of Zuckerkandl, may receive some interesting additions from paleontology. While in no sense intending to affirm any genetic relations between the dinosaurs and mammals, it is yet an interesting fact that a large sinus occurs in the sphenoidal region of dinosaurs and labyrinthodonts. It has previously been largely confused with the pituitary fossa near which it lies, but recent work tends to show a distinction between this fossa for the lodgment of the hypophysis and the *recessus basisphenoidalis* as it is called by Osborn¹, who has figured this cavity very clearly in *Tyrannosaurus rex*, the huge carnivorous dinosaur from the Cretaceous. The

¹ Osborn, H. F., 1912, *Mem. Amer. Mus. Nat. Hist.*, N. S., Vol. 1, Pt. 1, Pls. III and IV.

cavity in this dinosaur is quite extensive and corresponds in position to the human sphenoidal sinus and resembles this structure in some of its complications such as are occasionally found in man. The structure seems to occupy portions of both the basisphenoid and the basioccipital and to extend a considerable distance toward the occipital condyle. There are five possibly six saccular divisions of the sphenoidal sinus (*recessus basisphenoidalis*). These divisions recall the saccular divisions of the sphenoidal and frontal sinuses of man and from their smooth walls one would expect to find a membranous lining as in man. So far as I am aware this cavity has no connection with the nasal cavity although such a connection may be demonstrated from additional or from a restudy of present material. The recess lies below and between the points of exit of the third and twelfth cranial nerves the mass of the brain being immediately above it. Several authors have observed a similar depression in the sphenoidal region of the Labyrinthodont skull and in other primitive vertebrates notably the early reptiles. It is a well known fact that the hypophysis and particularly the posterior portion of this structure is in the early land vertebrates quite large and it has been the natural assumption that the large recess near where the hypophysis occurs should lodge the glandular organ but it is entirely probable that the recess is the sphenoidal sinus. There is no necessity of adopting Osborn's term *recessus basisphenoidalis* since there is no doubt that the structure corresponds well with the *sinus sphenoidalis* of man. It is to be hoped that someone will take up the question of the general homologies of these cavities in different groups of vertebrates so that we may have a firm basis on which to work. The value of fossil animals in furnishing facts of anatomical importance has never been fully realized and it is to be hoped that an attempt will be made to fill this gap.

ROY L. MOODIE

DEPARTMENT OF ANATOMY
THE UNIVERSITY OF ILLINOIS,
CHICAGO, ILLINOIS

SCIENTIFIC BOOKS

Human Physiology By PROFESSOR LUIGI LUCIANI. In four volumes. Volume II. Translated from the Italian by FRANCIS A. WELBY. London 1913.

The realm of physiology has become so extensive that the preparation of an encyclopedic treatise on the subject by a single author is a notable intellectual feat. The admirable manner in which Luciani has accomplished this feat in his *Fisiologia dell Uomo* is testified to by translations which have been made into both Spanish and German. Not only does the book include a review of recent and generally accepted observations and interpretations but also in many subjects an account of the historical development of our knowledge from ancient to modern times. The reader is thus given a perspective which is rarely obtained except by particular historical research.

A very considerable part of the value of Luciani's great handbook arises from his generous citation of original sources both old and recent. This feature gives the exposition a permanent utility for the careful student who desires to become acquainted with reports by the discoverers themselves. Such a student should not depend wholly on English and German references to literature; he would do well to examine also French and Italian summaries for it must be admitted there are not infrequently possibilities of tracing work thus which has not been represented where we have been most accustomed to look. Luciani's bibliographies present a rich mine of references to Italian as well as to other original papers.

The present volume (number II of the four volumes of an English translation) is a good example of the whole. It is concerned with the internal secretions, the digestive secretions, the processes of digestion both mechanical and chemical absorption and excretion. Many of the illustrations are taken from the original investigations and a number of them are colored. The chief criticism that can be made against the work is that during the time required for its writing and being translated physiology has been going

forward so rapidly that important researches of the past four or five years are not found included in it. This defect however, as intimated above, may be regarded as compensated for by the comprehensive and historical sweep which characterizes Luciani's survey of the subject. W B CANNON

The Wonder of Life By J ARTHUR THOMSON New York, Henry Holt and Company 1914

Once more we are indebted to Professor Thomson for a semipopular work on biology, this time with contents of a very miscellaneous character better to reflect the varied aspects of living nature. We have, in fact, a biological (mainly zoological) scrap book, full of interesting matters gleaned from more or less recent literature carefully selected and digested for our benefit. All this is loosely thrown together under several general headings, "The Drama of Life" "The Haunts of Life" "The Insurgence of Life" "The Ways of Life," "The Web of Life" "The Cycle of Life" and "The Wonder of Life" with more than 300 separate minor topics. Each chapter is headed by a selection from the aphorisms of Goethe as translated by Huxley. The book is admirably adapted for "supplementary reading" in a course on biology or zoology, or it might itself be made the basis of a seminar course. Its great value lies in its wide scope and breadth of view, with every emphasis on vital phenomena rather than on morphological details or classification. It is addressed, however, to an educated public, and even in places presupposes more zoological knowledge than most of us can boast. For example, on page 105 we are pulled up short by the startling announcement that "no one expects to find a Crustacean like *Byotrephes longimanus* in a pond." It is probably true that very few have ever approached a pond with any such expectation! Doubtless it is good for us, however, to bump now and again into things we do not understand, merely to diminish that conceit which too readily develops after reading discussions so lucid as those of Professor Thomson.

The specialist will here and there find things not quite up to date, or stated without sufficient reference to diverse points of view, but the general impression gained is that the work is admirably done and that in all probability no other naturalist could have done it better, if so well. The illustrations including many colored plates are pleasing and instructive, but not up to the standard of the text. Some are really bad as Fig 81, a colored plate of leaf-insects (*Phyllium*). The coloring of the foliage, to correspond with the insects is unnatural and without any adequate basis, while the insects are drawn from mounted specimens with the legs spread in the conventional way, without any reference to the plant on which they are supposed to be resting! The most ridiculous object is the young one shown as resting on a nearly upright branch, with its legs waving wildly in the air. The whole thing is certainly as it stands, a piece of "nature faking." Fig 39, representing young spiders shows some of them with the head and thorax separate like an insect.

There is a passage on page 595, beginning the discussion of the Transmissibility of Acquired Characters which indicates that such transmission is perfectly easy in unicellular animals, which simply divide into two. Jennings has well shown the fallacy of this naive conception, and it seems surprising that Professor Thomson should offer it not merely as an idea, but as a well known fact.

UNIVERSITY OF COLORADO

SPECIAL ARTICLES

MICRODISSOCIATION STUDIES ON THE GERM CELL¹

THIS paper records a continuation of the observations published recently² in SCIENCE on the male germ cells of the grasshopper, *Disosteira Carolina*, and of the cockroach, *Periplaneta Americana*. The cells were iso-

¹ Slightly modified from a paper read before the American Society of Zoologists, Philadelphia, December 29, 1914.

² Robert Chambers, Jr., "Some Physical Properties of the Cell Nucleus," SCIENCE, N S, XL, p 824, 1914.

lated and studied by means of microdissection and vital staining in a hanging drop of the insect body fluid in Barber's moist chamber.

The cytoplasm exhibits an extreme variability in its consistency. On tearing it may go into solution, setting free the nucleus and the cytoplasmic granules. Often the cytoplasm goes into solution with a rapidity suggestive of an explosion. A slight tearing of the surface is followed by a moment of apparent inactivity. Then comes a slight convulsive movement and the torn surface opens up, a swelling appearing especially at this place. Within a few seconds nothing remains but the nucleus and the mitochondria in the form of granules or a network. The nucleus in its turn swells and goes into solution. The mitochondria persist for a much longer time. Individuals are also met with whose cells retain their shape, the torn region being gradually obliterated by a closing in of the surrounding cytoplasm.

It is significant that all the cells of a given individual are constantly uniform in their behavior.

In an attempt to ascertain the cause for this variability in the consistency of the protoplasm a series of experiments has been planned one of which is the investigation of the germ cells of food and water starved individuals. Cockroaches starved for three weeks in a dry heated room were found uniformly to possess germ cells remarkable for their toughness and resistance to mechanical injury.

'Physiological' salt solutions in various dilutions were all found to produce a swelling effect on the cell. The first evidence of this in isolated cells is the assumption of a spherical shape. The addition of a trace of egg albumin counteracts the swelling to a slight extent. As swelling proceeds the viscosity of the protoplasm at first increases, agglutination phenomena becoming very marked. Later the viscosity is lost, possibly due to the increased imbibition of water.

When observed in body fluid, the cells tend to keep their irregular shapes. Spermatoocytes exhibit slow amoeboid movements. Isolated cells, however, soon become spherical.

They also become spherical and swell on injury as when they are punctured with a needle.

The mitochondria in the primary spermatocyte of *Drosophila* form a voluminous granular network surrounding the nucleus plainly visible in the fresh unstained cell. The delicate tracery of the mitochondrial structures in this and in subsequent stages is shown beautifully with Janus green, beside which similar structures seen in fixed material appear crude and in many respects erroneous. If the Janus green stain be heavy, its coagulative effect is apparent in the increase and clumping together of the granules. If the cell be torn, the cytoplasm goes into solution and the stain very soon fades out the granules swell and coalesce forming irregular lumpy masses which persist for a long time.

During metaphase the mitochondrial network is pulled out into a spindle shaped structure investing the viscous kinoplasmic material. Tearing of the cytoplasm causes a loss in the bipolar arrangement of the cell structures, the mitochondrial strands wrinkle and the whole spindle becomes distorted. The chromosomes scatter. Within a few minutes the relatively dense kinoplasmic mass goes into solution leaving the mitochondrial network with the chromosomes irregularly dispersed inside. In one such case two spermatozoa corkscrewed their way between the meshes of the mitochondrial spindle. Whenever their tails touched the viscous material of the meshes violent lashings were necessary to set themselves free. One struck its head against a mesh and was held prisoner for several minutes until the viscosity of the material was decreased during the dissolution process. The other spermatozoon hit a chromosome which stuck to its tail and the spermatozoon twirled away dragging off the chromosome.

During anaphase and telophase the granules and strands of the mitochondrial network are lengthened into delicate filamentous threads lying between the two groups of chromosomes. These are the interzonal filaments or the spindle rest described in fixed material. As constriction between the daughter cells progresses, the tension of the fila-

ments diminishes. Their tips vacuolize and appear lumpy giving evidence again of a network arrangement of granules. As the constriction deepens the cluster assumes the form of an hour glass. The Janus green stain now disappears at the middle as if the mitochondrial material were drawn away or had gone into solution. In late telophase the substance of one daughter cell may be torn away from the other cell leaving the mitochondrial filaments projecting in naked strands which soon wrinkle and curl and finally coalesce into a lumpy mass.

Cells in late anaphase and telophase may be caused to assume a spherical shape by mechanical agitation or tearing with the needle. The mitochondrial spindle is then very much distorted, the filaments become wrinkled and tangled. At the end of the cell division each daughter cell contains a cluster of mitochondrial filaments which have already begun to be transformed into a granular network mass which gradually spreads around the nucleus. The mitochondria are not stable structures. Granules at one moment may draw out into threads or coalesce with their neighbors or go into solution freshly formed granules replacing them.

In the spermatid the mitochondria mass at one side of the nucleus to form the *Nebenkern*. The mitochondrial granules at first loosely distributed soon collect into a compact body which stains a solid blue with Janus green. On dissecting the *Nebenkern* out of the cell it disintegrates into granules which persist as such for some time.

The development of the axial filament was closely followed in the cockroach. It originates in connection with an apparent sloughing off of material from the surface of the *Nebenkern*. The coiled filament thus formed is bordered on two sides with a longitudinal row of granules collected at very regular intervals in small uniform clumps. The filament itself does not stain with Janus green the bordering granules however become in tensely blue. One may watch the filament gradually uncoil and loosen from the *Nebenkern*. One end is inserted in a conical knob

(the blepharoblast) on the surface of the cell nucleus. As it uncoils it forms a loop curving along the periphery of the cell. The uncoiling is accompanied by an oscillatory movement which begins at the knob and passes in a wave along the filament. This movement gains in strength until the whole body of the cell is thrown into ever recurring waves. The movement is instantly arrested when the cytoplasm is torn by the needle. The cytoplasm then goes into solution and the filament either straightens out or deepens its curve possibly according to the character of the wave at the moment the spermatid is torn. The filament remains attached to the nucleus and may be dragged about with a needle. It is elastic and rigid and keeps its shape perfectly for the short time before it goes into solution. During the process of its elongation the spermatid is very susceptible to touch. A slight prick with the needle will cause it to assume a spherical shape. This is accompanied by a distortion of the double row of granules alongside the axial filament so that one may observe the wave pass along one row slightly ahead of that along the other.

When examined in Ringer's fluid or when the spermatid is disturbed by the needle the clumps tend to round off in the form of vesicles. This is especially noticeable in the case of the two largest clumps close to the nucleus. Such an appearance is commonly met with in fixed material. As the filament straightens the cell is drawn out into an attenuated body. The granules along the filament coalesce to form two narrow uniformly homogeneous bands which extend alongside the spherical nucleus to the anterior tip of the spermatid. The nucleus condenses into an optically homogeneous and highly refractive body which gradually lengthens into the rod shape of the mature spermatozoon. A large double clump of granules which lies immediately behind the nucleus condenses and forms the neck piece. The throwing off of clumps of cytoplasm was never observed except in preparations in salt solutions or in old body fluid preparations where such cytolytic action was apparent in all the cells present.

The perforatorium of the ripe spermatozoon tapers off in the form of a corkscrew. In Ringer's fluid it swells into a bleb like process and as such is figured by Duesberg and Morse. The tail has two movements a whip-like lash and a twirl its base being used as a pivot. These two movements whirl the spermatozoon forward in a corkscrew fashion. It may be noted that the lashing movement of the spermatozoon tail is directly comparable to the waving of the axial filament within the spermatid.

In conclusion I wish to emphasize the following points drawn from this and from my previous paper.

1 As far as nuclear structures are concerned the study of fresh material corroborates in many interesting details the observations made in fixed material. Both methods are necessary for a proper understanding of the structures. Our present fixing methods however are useless for the study of cytoplasmic and mitochondrial structures and should be replaced by the study of fresh material.

2 Physiological 'salt solutions are more or less injurious to the cells studied which are normally bathed by organic fluids & liquid colloids.

3 Puncture of a cell by a needle causes irreparable injury. When the injury is slight it at first hastens the normal reversible changes in the physical states of the colloids in the cell but soon transforms them to an abnormal condition from which the cell does not recover.

4 Injury to the cell is always followed by swelling accompanied by an increased inhibition of water.

5 A tension exists in the cell during division which is immediately lost when any part of the cell is torn.

6 Amoeboid activities are prevalent among the germ cells. In this way extensive movements occur within the cysts of the testis follicle. When set free in a liquid medium, the amoeboid processes are very soon retracted and the cells assume a spherical shape.

The movement in waves of the axial filament of the spermatid starts at the conical knob on the nucleus and accompanies the uncoiling of the filament from the surface of the Nebenkern.

7 The staining of the mitochondria by Janus is probably not due to a chemical combination. In time the stain fades out of the cell. If the stained structure be brought into immediate contact with a liquid it is washed out almost immediately.

8 Janus green if used in sufficient concentration will stain the nuclear structures. The dye is reduced to the red safranin even in the presence of abundant air. This has been observed in all stages of the germ cells and also in motile spermatozoa. Such cells however soon die. Dead cells take up the blue stain readily the nuclear structures showing beautifully.

9 Janus green being a basic dye coagulates albuminous substances. In living cells this coagulating effect is very noticeable. The stain therefore can not be used as the sole means for identifying mitochondria.

10 The mitochondria in the Orthopteran germ cell are in accord with those studied by the Lewises* in the tissue cells of the chick. They can not be classed as persistent structures. They pass from a granular stage into strands they may coalesce into homogeneous masses they disappear and reappear and must be merely changes in physical states of the colloids which compose the cytoplasm.

UNIVERSITY OF CINCINNATI

SOME NEW CASES OF APOGAMY IN FERNS PRELIMINARY NOTE

SEVERAL cultures of *Aspidium trissumense*, *Pellaea adiantoides* and *Lastrea chrysoloba* were made beginning June 25, 1914. The spores were sown on sphagnum which was first placed in small stender dishes saturated with a one tenth per cent. Knops solution, and then thoroughly sterilized in an oven.

* M. R. and W. H. Lewis. "Mitochondria in Tissue Culture." SCIENCE N. S. XXXIX, p. 330. 1914.

So far as I have been able to observe, nothing unusual occurs in the early stages of development of the prothallia of any of the three species. The prothallia of *Aspidium tsussimensense* and of *Lastrea chrysoloba* grow to a large size and are typically heart shaped. The prothallia of *Pellaea adiantoides* are much smaller and in some respects resemble those of *Pellaea atropurpurea*, in which species I described apogamy in 1910.¹ Anthridia are produced in large numbers on many of the prothallia of each of the three species here under consideration. The antherozoids are actively motile and appear to be normal in every respect. Archegonia have been observed on some of the prothallia of *Lastrea chrysoloba*.

On the well developed cushion of the prothallium of *Aspidium tsussimensense*, usually at some distance back of the apical notch, a number of papillate projections appear. These projections frequently occur in groups. Some times each consists of a single cell, but more frequently of a single row of cells. In this portion of the prothallium, usually after the projections have been formed, a compact mass of cells appears which develops into an embryo. At an early stage in the formation of this apogamous embryo, tracheids are produced. The developing embryo never produces a foot. The primary leaf as a rule is formed in advance of the primary root. The stem appears later than the leaf and the root. Even while the embryo is very young, numerous scales appear on the petiole of its primary leaf. These resemble the scales so characteristic of the mature sporophyte.

The prothallia of *Pellaea adiantoides* also produce embryos apogamously. The development of the embryos appears to be similar to that described in my previous paper for that of *Pellaea atropurpurea*. In a number of cases in my cultures the embryo has already formed the primary leaf and the primary root.

When the embryo of *Lastrea chrysoloba* is about to form a small light region appears between the apical notch and the cushion. In this region the embryo is developed. In all

of my cultures the apogamously produced embryo has just begun to project above the surface of the prothallium. Embryos developed from a fertilized egg have not been found. When prothallia bearing archegonia are placed in a drop of water on a slide and examined microscopically, the archegonia can be observed to open, but antherozoids do not appear to be attracted to them.

While the prothallia of these species of ferns were being grown, numerous cultures of other species maintained under the same conditions of nutrition, light, temperature and moisture, contained prothallia bearing anthridia and archegonia, and in some cases embryos were produced upon these prothallia as a result of fertilization. THE AMERICAN SOCIETY FOR PHARMACOLOGY AND EXPERIMENTAL THERAPEUTICS

THE sixth annual meeting of the Pharmacological Society was held in St. Louis at Washington University Medical School on December 27-30, 1914. There were five scientific sessions, three of them being joint meetings with the other members of the Federation of American Societies for Experimental Biology, the Physiological Society, the Biochemical Society and the Society for Experimental Pathology.

The following officers were elected in the Pharmacological Society for the year 1915:

President Torald Sollmann

Secretary John Auer

Treasurer Wm. delb MacNider

Additional members of the council Worth Hale and D. E. Jackson

Membership Committee S. J. Meltzer (term expires 1917)

Election of New Members The following candidates were approved by the membership committee, passed by the council and elected by the society: Dr. F. C. Becht, University of Chicago; Dr. W. H. Brown, Rockefeller Institute; Dr. F. L. Gates, Rockefeller Institute.

The attendance was excellent, but the eastern section of the country was not as well represented as could be desired.

The scientific sessions were opened on Monday, December 28, at 9 A. M. by a joint meeting of the

¹ Bot. Gaz., 42, 400-401, 1910

four societies, Dr Graham Luak presiding. The following papers were read and discussed:

"Experimental Hyperthyroidism," by W B Cannon, C A Binger (by invitation) and R Fitz (by invitation)

"Further Observations on the Etiology of Goiter in Fish" (read by title), by David Marine

"Studies on Experimental Cretinism," by H R Basinger (by invitation) and A L Tatum

"A Research into the Function of the Thyroid" (read by title), by G W Crile, F W Hitchings (by invitation) and J B Austin (by invitation)

"The Effect of Repeated Injections of Pituitrin on Milk Secretion" (read by title), by S Simpson and R L Hill (by invitation)

"The Action of Pituitrin on the Mammary Gland," by W L Ganes (by invitation)

"On the Mechanism of Pituitrous Diuresis" (read by title), F P Knowlton and A C Silverman (by invitation)

"The Several Factors Involved in the Standardization of Pituitary Extracts," by George B Roth

The first scientific meeting of the Pharmacological Society took place in the afternoon at 2 P M, Dr Sollmann presiding. The following papers were read and discussed:

"The Fatal Dose of Various Substances on Intravenous Injection in the Guinea pig," by S Amberg and H F Helmholz

"Experimental and Clinical Research into Alkalosis, Acidity and Anesthesia" (read by title), by G W Crile

"Effects of Chelidonium on Surviving Organs," by P J Hanzlik

"The Effect of Temperature on the Response of Frogs to Oushain," by T Sollmann, W L Mendenhall (by invitation) and J L Stingle (by invitation)

"Artificial Cerebral Circulation after Circulatory Isolation of the Mammalian Brain," by E D Brown

"The Uterine Action of Quinidin, Cinchonin and Cinchonidin," by Worth Hale

"Some Vasomotor Reactions in the Liver," by C D Edmunds

"Distribution of Solutions in Cardiotomized Frogs with Destroyed or Inactive Lymph Hearts," by T S Githens and S J Meltzer

"The Influence of Intraintestinal Administration of Magnesium Sulphate upon the Production of Hyaline Casts in Dogs," by F L Gates (by invitation) and S J Meltzer

The second scientific meeting was held on Tuesday morning at 9 o'clock, Dr Sollmann in the chair. The following papers were presented and discussed:

"A Study of the Relative Importance of the Vascular Mechanism of the Kidney and of the Epithelial Element of the Kidney in Determining the Efficiency of Various Diuretics" (read by title), by W deB MacNider

"Cross-tolerance of Drugs," by H B Myers (by invitation)

"Vascular Reactions in Poisoning from Diphtheria Toxin," by H B Myers (by invitation) and G B Wallace

"The Action of Digitalis in Experimental Auricular Fibrillation," by A D Hirschfelder

"The Effects of Drugs upon the Circulation in the Pia Mater and the Retinal Vessels," by A D Hirschfelder

"The Action of Camphor on the Circulation," by Clyde Brooks and J D Heard (by invitation)

"The Effect of CO₂ upon the Convulsant Action of Acid Fuchsin in Frogs" by Don R Joseph

"The Mechanism of the Toxic Action of the Heavy Metals on the Isolated Heart," by Carl Voegtlin

"An Analysis of the Action of Digitalin on the Cardiac Inhibitory Center and on the Cardiac Muscles," by C W Greene, L R Boutwell (by invitation) and J O Peeler (by invitation)

"A Comparative Study of the Influence of the Solvent upon the Toxicity of Thymol," by W H Schultz

"The Reaction of Hookworm Larvae to Certain Chemicals," by W H Schultz

"A Further Observation on the T-wave when Digitalis is Given," by A E Cohn

The next meeting in the afternoon was a joint scientific session of the societies forming the Federation and the following papers were read and discussed, Dr Sollmann presiding:

"The Influence of Sodium Carbonate on the Glycosuria, Hyperglycemia and the Respiratory Metabolism of Depancreatized Dogs" (read by title), by J R Murlin and B Kramer (by invitation)

"The Influence of Depancreatization upon the State of Glycemia after Intravenous Injections of Dextrose in Dogs," by I S Kleiner and S J Meltzer

"The Possibility that some of the Hepatic Glycogen May Become Converted into Other Substances than Dextrose," by J J R. Macleod.

"Narcotics in Phlorhizin Diabetes," by R T Woodyatt

"Adrenal Deficiency" by R S Hoskins

"Hypoglycemia," by H McGuigan

"Some Effects of Adrenalin when Injected into the Respiratory Tract," by J Auer and F L Gates (by invitation)

"The Relation of the Adrenals to the Brain" (read by title), by G W Crile, F W Hitchings (by invitation) and J B Austin (by invitation)

"Further Observations of the Origin of Hydrochloric Acid in the Stomach" (read by title), by A B Macallum and J B Collip (by invitation)

"The Effect of Various Fluids and Cereals on Gastric Secretion" (read by title), by C C Fowler (by invitation), M E Rehfus (by invitation) and P B Hawk

"The Distribution of Gastrin in the Body," by R W Keeton (by invitation) and F C Koch

"The Relation of the Digestion Contractions to the Hunger Contractions of the Stomach (Dog, Man)," by F F Rogers and L L Hardt (by invitation)

The third joint session was held on Wednesday morning December 30, Dr Lusk presiding. The following papers and demonstrations were presented

"Recuperation Nitrogen Metabolism of a Man when Ingesting Successively a Non protein and a Normal Diet after a Seven day Fast," by F D Zeman (by invitation), J Kohn (by invitation) and P E Howe

"Some Studies in Autolysis," by H C Bradley

"The Diastase of the Blood," by H McGuigan and C L v Hess (by invitation)

"The Rate of Oxidation of Enzymes and their Corresponding Proenzymes," by W E Burge

"The Harmful Effect of an Exclusive Vegetable Diet" by C Voegtlin

"The Effect of Long continued Feeding of Saponin from the Bark of *Guaiacum officinale*" (read by title), by C L Alsberg and C S Smith (by invitation)

"Fat Infiltration of the Liver and Kidney Induced by Diet," by E L Opie and L B Alford (by invitation)

"On the Nature of the Hepatic Fatty Infiltration in Late Pregnancy and Early Lactation," by V H Mottram (by invitation)

"The Synthesis of Hippuric Acid in Experimental Tartrate Nephritis in Rabbit," by F B Kingsbury (by invitation) and E T Bell (by invitation)

Demonstrations

Blood Pressure Method, by C Brooks and A B Luckhardt

Demonstration of a Point to point Method for Analyzing Induction Shocks by means of the String Galvanometer, by J Erlanger and W E Garrey

A Device for Projecting a Small Spot of Light Suitable for Exploring Photo sensitive Areas, by B M Potter (by invitation)

Demonstration of the Effect of Sodium Iodoxybenzoate on Inflammation caused by Mustard Oil, by S Amberg and D McClure (by invitation)

An Arrangement of the Porter Clock to Give Three Time Intervals at the Same Time, by Worth Hale

A Portable Respiratory Machine Furnishing Continuous, Intermittent and Remittent Streams of Air, by F L Gates (by invitation)

The Determination of Blood Sugar, by P A Shaffer

On Wednesday afternoon the local committee arranged a series of enjoyable visits to the St Louis hospitals and laboratories and also to the beautifully located impressive buildings of Washington University

Dinners and Smokers—This part of the program was inaugurated by a dinner given by the local committee on Sunday evening, December 27, to the officers and councils of the constituent societies of the federation and of the Anatomists

The customary and universally satisfactory in formal subscription dinners and smokers were held on the evenings of December 28, 29 and 30, the first two at the Hotel Jefferson and the last one at the Hotel Warwick. Perhaps the most enjoyable of these was the first: on December 28, when a number of excellent speeches were delivered, the speakers being the guests of the evening, Mr R S Brookings, Dr Graham Lusk, Dr J George Adams and Dr G Carl Huber

At the last executive session of the Pharmacological Society a motion was put and passed unanimously to thank the authorities of Washington University for their hospitality and the local committee for its broad and efficient efforts to render the stay of their guests in St Louis as pleasant and profitable as possible

The next meeting of the federation will be held in 1915 in Boston at the Harvard Medical School

THE American Association for the Advancement of Science represents the recognized and organized sciences. One by one new groups have been added to it, as those groups have won public recognition and have demonstrated that they are interested broadly in the enlargement of human knowledge. Half the letters of the alphabet are required to designate these groups represented in organized sections, indicating the breadth and vitality of our scientific inquiry. The last of these sections is agriculture—not the occupation agriculture, but the assembly of scientific research that deals with the problems of the occupation and of the living resulting from the occupation. We begin the work of this section to-day. It means much, I think, for this work that it has now been recognized as worthy to occupy a place on the programs with the older and the better standardized groups. I hope that we shall be worthy of the fellowship; and I trust that the Association itself will gain something by what we and our successors may bring to it in the future.

There is no field of scientific research that belongs exclusively to agriculture and not to other groups. The peculiarity of the research in this field lies in its association for the purpose of improving a great industry and of making a particular contribution thereby to the national life. The

! Address of the Vice-president and Chairman of Section L. American Association for the Advancement of Science, Philadelphia, December, 1915.

MSB. Intended for publication and books, etc., intended for review should be sent to Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

problems may be physical, chemical, biological, meteorological, mechanical, economic, social and otherwise; and therefore they are in themselves historically worthy the recognition of men and women engaged in public and scientific work. Nor are they contaminated by contact with the earth, seeing that they come out of the earth; nor again by contact with men who work, seeing that men are useful and worthy when they work.

And yet, by common consent and in the process of evolution, there is a field that is known as agricultural science. It would be vain for me to define it; probably I should succeed only to confine it. You shall learn what it is as the programs of Section M are placed before you in the succeeding years. This year, aside from the required address of the vice-president, the program considers some of the problems of economics as related specially to agriculture; those subjects are underlying, and the addresses will be interesting and important.

The subject of the symposium of this section suggests the general line of effort that Section M may profitably pursue. The section will not find it to its advantage, I think, to discuss the technical problems of the production of crops and animals. It will rather devote itself to questions that relate agriculture to public welfare and to problems of general interest, dealing with policies and the large social, economic, educational and political results. It is important that the attitude of all the sciences be brought to bear on these questions, and I look for the greatest usefulness for Section M in bringing together the agricultural work with the other work of the association. I hope that as time goes on there may be joint discussions of Section M with other sections or groups represented in the

Convocation Week. Such discussions should result in much mutual advantage.

The agricultural situation is now much in the public mind. It is widely discussed in the press, which shows that it has news value. Much of this value is merely of superficial and temporary interest. Much of it represents a desire to try new remedies for old ills. Many of these remedies will not work. We must be prepared for some loss of public interest in them as time goes on. We are now in a publicity stage of our rural development. It would seem that the news-gathering and some other agencies discover these movements after the work of many constructive spirits has set them going and has laid real foundations; and not these foundations, but only detached items of passing interest, may be known of any large part of the public. I hope that we shall not be disturbed by this circumstance nor let it interfere with good work, however much we may deplore the false expectations that may result.

It has been my privilege for one third of a century to have known rather closely many of the men and women who have been instrumental in bringing the rural problem to its present stage of advancement. They have been public-minded, able, far-seeing men and women, and they have rendered an unmeasurable service. The rural movement has been brought to its present state without any demand for special privilege, without bolstering by factitious legislation, and to a remarkable degree without self-seeking. It is based in a real regard for the welfare of all the people, rather than for rural people exclusively.

Great public-service institutions have been founded in the rural movement. The United States Department of Agriculture has grown to be one of the notable governmental establishments of the world, extend-

ing itself to a multitude of interests and operating with remarkable effectiveness. The chain of colleges of agriculture and experiment stations, generously cooperative between nation and state, is unlike any other development anywhere, meaning more, I think, for the future welfare and peace of the people than any one of us yet foresees. There is the finest fraternalism, and yet without clannishness, between these great agencies, setting a good example in public service. And to these agencies we are to add the state departments of agriculture, the work of private endowments, although yet in its infancy, the growing and very desirable contact with the rural field of many institutions of learning. All these agencies comprise a distinctly modern phase of public activity.

Now, the problem is to relate all this work to the development of a democracy. I am not thinking so much of the development of a form of government as of a real democratic expression on the part of the people. Agriculture is our bottom industry. As we organize its affairs, so to a great degree shall we secure the results in society in general.

I desire to discuss certain questions that bear somewhat on this underlying problem. I shall approach these questions mostly from the point of view of our present public-service institutions for agriculture, leaving the other or non-public phases of the problem for consideration one year hence. I do not presume to make specifications for the institutions; but the questions may be discussed and perhaps we can do something to protect the institutions from demands that should not be made of them. Perhaps you will make some mental applications of the discussion to other public work than that which is specially agricultural.

It is auspicious, and perhaps it is fortu-

nate, that this new section comes into being at a time when a vast new organized movement in the interest of agriculture is taking hold of this country. This movement is connected very intimately with government, and therefore with policies affecting all the people; and it is possible, even in a democracy, that such a trend, or even such a formalizing, may arise in the beginning as can not be greatly modified, or much changed if change should be necessary, in any number of years. You know that I refer to the Agricultural Extension Act which was signed by President Wilson on the eighth of last May. No such national plan on such a scale has ever been attempted; and it almost staggers one when one even partly comprehends the tremendous consequences that in all likelihood will come of it. The significance of it is not yet grasped by the great body of the people.

We are at the parting of the ways. For years without number—for years that run into the centuries when men have slaughtered each other on many fields thinking that they were on the fields of honor, when many awful despotisms have ground men into the dust, the despotisms thinking themselves divine—for all these years there have been men on the land trying to see the light, trying to make mankind hear, hoping but never realizing. They have been the pawns on the great battlefields, men taken out of the peasantries to be hurled against other men they did not know and for no rewards except further enslavement. They may even have been developed to a high degree of manual or technical skill that they might the better support governments to make conquests. They have been on the bottom, upholding the whole superstructure and pressed into the earth by the weight of it. When the

final history is written, the lot of the man on the land will be the saddest chapter.

But in the nineteenth century, the man at the bottom began really to be recognized politically. This recognition is of two kinds, the use that a government can make in its own interest of a highly efficient husbandry, and the desire to give the husbandman full opportunity and full justice. I hope that in these times the latter motive always prevails. It is the only course of safety.

We have developed the institutions on public funds to train the farmer and to give him voice. These institutions are of vast importance in the founding of a people. The folk are to be developed in themselves rather than by class legislation, or by favor of government, or by any attitude of benevolence from without. And now, the great extension law, for which so many men and women have worked so long, is a fact, and means are to be provided whereby the farmer may find help at his own door. A new agency in the world has now received the sanction of the people, and we are just beginning to organize it.

It is a noble expression of confidence in the persons who have prepared the people for this departure, that the legislation should have been so generous and so complete.

The days of our propaganda are passed. No longer are we agricultural crusaders, seeking to get a hearing with the powers that control, making the work felt in the nation, energizing the farming people to express themselves. I fear that this changed relation is not understood by some persons; and hereupon we come to a crucial and perhaps to a dangerous situation. Some of us have not expected the recognition to come so soon or so completely, and it may be difficult for us to understand what has happened or to readjust our activities.

There are three phases of the situation that seem to call for special consideration at this turn in affairs, one of which has no novelty, and the second and third of which appear not to have received sufficient attention.

I. THE NECESSITY OF FUNDAMENTAL KNOWLEDGE

Although there has necessarily been something of the effort at conversion, the country-life movement is not a propaganda. It is the expression of a rapidly crystallizing desire to make rural life all that it is capable of becoming, and to understand and to utilize in the best way all the natural products of the earth.

All this requires knowledge; and knowledge of this kind demands careful inquiry. There must be a certain relation or equation between the research effort and the teaching effort. The enlargement of one ought to be conditioned on the enlargement of the other; and certainly we ought to know before we teach. I hope that the new extension work will demand a great stimulation of research. No subject makes great headway, no people makes great progress, unless it rests on investigation and discovery and feels the stimulation of exploration in fresh fields.

Particularly do we need the balance and the check in extension teaching in agriculture, where the field is so diverse, the people so numerous and so scattered, the teachers so variously trained, and the traditional errors so many. Extension work is not propaganda; it is teaching where the people are rather than where the matriculated students are; and while it may not go so deep, it must be as true and as well standardized to ascertained fact as is the other kind of teaching. The vitality of the extension teaching, as of any other teaching in natural science, will depend on the body of exact knowledge that lies behind it.

This being true, then we must see that appropriations for extension teaching in the years to come are not out of proportion to appropriations for research. I hope that we shall soon find a wide-spread expression amongst the people for a more complete endowment of fundamental investigation in subjects related to our agricultural industries.

I will digress to say that not everything is research, in agriculture or elsewhere, that happens to bear the name. Undoubtedly research, as such, has been over-glorified. There is no sanctity in research that does not inhere also in any other good and honest effort requiring equal ability. The teacher is as worthy of honor as the investigator.

Neither is research a refuge. Certain persons who bear something of a disdain for the affairs of the world are likely to be set at more or less interesting problems under the denomination of "original investigation" and "research," and "pieces of work." Here they may find shelter and protection, and a certain deference that is very conducive to peace of mind. They are supposed "to publish," whereupon their standing is established among their fellows. It may not be necessary to raise the question as to the significance of the publication or whether it reaches any result.

We are so insistent on technical accuracy that we are likely to eliminate the imagination; and without imagination no man can accomplish real research. Result is that undoubtedly we have worthy young persons in the institutions of many kinds who are practically accomplishing little beyond receiving support.

So I am thinking of research that follows a program looking toward a solution. Each of the items of such work is in itself a contribution. Not one is meaningless, and not

one is made *in vacuo*. Such investigations constitute the very beginning and basis of our accomplishments. The very rapid and really significant progress accomplished in the agricultural field within recent years has been possible because of the basis of research, which has been such a conspicuous part of it. The contributions to knowledge in this department have been astounding in variety, remarkable in their applications to human welfare, and many of them worthy to rank with research of highest excellence in other fields. We have a notable momentum toward original inquiry of a high order in the agricultural subjects, and we should be zealous to see that it is not halted, overlooked or eclipsed. We must consider that research does not have within itself the elements of publicity, and that it must be guarded by the good opinion and the activity of such persons as frequent conventions like this.

It is not necessary to the broad results we seek that this research shall all be directly or immediately applicable to the arts of life. It does not matter if much of it remains practically unknown to the public. The effect of the accumulation of it, if it is good, will be beyond all price, establishing a foundation, providing a reservoir from which we may draw at will, giving us a sense of conquest and of power, developing a literature, and training many men whose judgment will be of the greatest value in the control of our rural affairs. Research in agriculture should look toward a solution, but not necessarily toward a definite application, although the purpose to apply does not make it any the less research or any the less worthy of respect.

Knowledge applies itself in the end. The best and the final application of it is in a new approach to the subject and a better philosophy of action. This is well illustrated in the great work of Darwin, which

we have now learned to apply in a thousand ways, because it has entered into our philosophies. So the accumulation of knowledge touching agriculture will give those who come after us a new grasp on the rural condition, a readjustment of ideas, and confidence in our ability to handle the situation. Good research, maintained continuously and without haste by the ablest men, will make its own application.

II. THE QUESTION OF PUBLICITY

Extension work in many kinds of subjects has seemed to some persons to be of the essence of publicity. This is a damaging error. We have already agreed, I hope, that it is not propaganda; nor is it publicity, or promulgation, or advertising, or exploitation. It is properly not work to be governed merely by expediency. It is educational work performed elsewhere; and as such it should have its own orderly program.

As newspaper popularity is dangerous to a person who engages in serious and productive work, so in future will a popularizing press-service publicity, under whatever name it may be called, raise against the colleges of agriculture and the experiment stations, and the extension teaching—or other similar enterprises—a presumption that it will be difficult to live down. Remember that the situation is changed. Consider also that the American is oversupplied with what is called news, and is likely to over-estimate the value of press publicity. The agricultural education work has again met the approval of the people as expressed in a piece of great legislation. It should no longer be necessary to make public sentiment.

It is said that only a certain rather small percentage of the farming people read the bulletins of the institutions, and that, therefore, there must be some means of publicity,

some making over of the literature, some new agency invoked, some peptonizing of the work, that shall interest every person. The fact as to percentages may be correctly stated, but the inference is very dangerous. The colleges and stations are not engaged in the dissemination of news; they are not in the press-bureau business. They have ample means of reaching the people through their students, their staff, their publications and their visitors. They should control their own avenues of dissemination, of course giving information and advice freely whenever requested. The reaching of all the people must come about very gradually and without haste. If one fourth of the farming people are informed, there need be no fear, and the remainder will be reached by regular and natural means as soon as they are ready to profit by the work.

It is doubtful whether any great movement or benefit is understood by more than one fourth of the people; and the knowledge of it passes very much from person to person in a hundred informal ways that are not known of the newspapers. The rise of public sentiment for a better agriculture does not depend on the numbers of persons who read the experiments at the institutions.

It is much to be desired that the bulletins shall be readable. It is presumed that all publications should be readable, seeing that they are published to be read. Good English, clear and attractive composition, lucid subdivision, the elimination of unessential parts, should make a bulletin readable by any person who has an interest in the subject; and it is not necessary that it be attractive in the newspaper sense. Such publications should be circulated widely, so far as persons seem to want them, and with the purpose ultimately to reach the entire constituency; and if some

fall to the waste-basket, it must be remembered that even the best seeds may fall on stony ground. I hope that the demand among the people for a greatly popularized bulletin literature—if such demand exists—may soon cease; at all events, we need not cater to it. The essential values and also the best scientific mode of presentation should be preserved. It must be remembered that the mode of presentation has teaching value in itself; the subject-matter may have only information-value.

Other agencies than literature, particularly than news-agency literature, must be found to carry the work to the people and to apply it there. The best results will come in the localities when the people begin to organize to receive the help. The people need more than pieces of information: they need stimulation and guidance. We look on the farm-bureau movement to accomplish very much in this way, if the motive power in it is kept with the people.

The natural and rational unfolding of the work as it issues from the institution, by means of its own agencies under its own control, will in time cover the field effectively. It is a great gain when any public institution or establishment, while still serving the people feelingly in a spirit of true democracy, passes the restless fever of publicity before the restlessness becomes chronic, and lays out a plan calculated to reach the results and then lets the process work itself out.

1:14

III. THE ORGANIZATION OF THE NEW WORK

The great Extension Act brings what is essentially a new policy into American educational procedure. Only in the mechanic arts and agriculture, as they are founded on the Land-Grant Act of 1862, do we have a national system of education; but even in this case the federal super-

vision in the states was at first none or nominal. With the passage of subsequent acts the federal control has become more pronounced.

Undoubtedly we have profited very much as a people by the many political, educational, legal and other experiments of the different states. We now have forty-eight of these great experiment stations—the forty-eight stars on the flag—each one attempting to work out a government that shall best meet the needs of its people. We should have gained much in regularity of procedure, and perhaps in economy of funds and in what is called efficiency, if our educational system had at first been nationalized; but we should have missed much more than we now have gained. This nationalized extension work proceeding in detail in every community in the Union will raise essentially a new principle, for us, in educational policy.

It is the common assumption that if congress appropriates money, congress (or the federal government) should control all the expenditure of it. I think this is a doubtful, if, in fact, not a dangerous doctrine. The money belongs to the people, and there should be no reason why congress may not appropriate some of it back to the people. It may be expended in the people's interest quite as well by states as by the federal government. Of course it should be honestly expended and for the purposes for which it is appropriated, but these are matters of detail that ought not to be difficult to arrange. Specially do we need some centralized power for the control of delinquencies, an office that the United States Department of Agriculture has sometimes been called upon to exert with much benefit; but this is a very different matter from controlling or making the programs in the beginning. It is very important in our great experiment in

democracy that we do not lose sight of the first principle in democracy, which is to let the control of policies and affairs rest directly back on the people.

Some enterprises should be much centralized, whether in a democracy or elsewhere; an example is the postal service: this is on the business side of government. Some enterprises should be decentralized; an example is a good part of the agricultural service: this is on the educational side of government.

Whether there is any danger in our new nationalized extension work, which we are all so glad to have and from which we expect so much, I suppose not one of us knows. But for myself, I have apprehension of the tendency to make some of the agricultural work into "projects" at Washington. If we are not careful, we shall not only too much centralize the work, but we shall tie it up in perplexing red-tape, official obstacles, and bookkeeping. The merit of the projects themselves and the intentions of the officers concerned in them are not involved in what I say; I speak only of the tendency of all government to formality and to crystallization, to machine work and to arm-chair regulations; and even at the risk of a somewhat lower so-called "efficiency" I should prefer for such work as investigating and teaching in agriculture, a dispersion of the initiative and responsibility, letting the coordination and standardizing arise very much from conference and very little from arbitrary regulation.

In the course of our experience in democracy, we have developed many checks against too great centralization. I hope that we may develop the checks effectively in this new welfare work in agriculture, a desire that I am aware is also strong with many of those who are concerned in the planning of it.

Twice I have spoken as if not convinced that the present insistence on "efficiency" in government is altogether sound. That is exactly the impression I desire to convey. As the term is now commonly applied, it is not a measure of good government.

Certain phrases and certain sets of ideas gain dominance at certain times. Just now the idea of administrative efficiency is uppermost. It seems necessarily to be the controlling factor in the progress of any business or any people. Certainly, a people should be efficient; but an efficient government may not mean an efficient people—it may mean quite the contrary or even the reverse. The primary purpose of government in these days, and particularly in this country, is to educate and to develop all the people and to lead them to express themselves freely and to the full, and to partake politically. And this is what governments may not do, and this is where they may fail even when their efficiency in administration is exact. A monarchic form may be executive more efficient than a democratic form; a despotic form may be more efficient than either. The justification of a democratic form of government lies in the fact that it is a means of education.

The final test of government is not executive efficiency. Every movement and every circumstance that takes starting-power and incentive away from the people, even though it makes for exacter administration, is to be challenged. It is specially to be deplored if this loss of starting-power affects the persons who deal first-hand with the surface of the planet and with the products that come directly out of it.

If it is important that the administration of agricultural work be not overmuch centralized at Washington, it is

equally true that it should not be too much centralized in the states. I hear that persons who object strongly to federal concentration may nevertheless decline to give the counties and the communities in their own states the benefit of any useful starting-power and autonomy. In fact, I am inclined to think that here at present lies one of our greatest dangers.

A strong centralization within the state may be the most hurtful kind of concentration, for it may more vitally affect the people at home. Here the question, remember, is not the most efficient formal administration, but the best results for the people. The farm-bureau work, for example, can never produce the background results of which it is capable if it is a strongly intrenched movement pushed out from one center, as from the college of agriculture or other institution. The college may be the guiding force, but it should not remove responsibility from the people of the localities, or offer them a kind of co-operation that is only the privilege of partaking in the college enterprises. I fear that some of our so-called cooperation in public work of many kinds is little more than to allow the cooperator to approve what the official administration has done.

There is no occasion for misunderstanding here. It is exactly because I want the college of agriculture to hold and to extend its leadership that I warn you against its assuming any dictatorship. I think the situation at this moment demands special caution. The college comes into new consciousness of power. Great forces are put in its hands. There is at present more promise of great results for the people on the land than in any other movement or situation within my recollection. It is just the moment to give the people in the neighborhoods all the freedom and all the responsibility they ought to have for their

own best development. The future will care very little for the mechanism of administration, but it will care very much for the results in the training of the folk.

There is a vast political significance to all this. Sooner or later the people rebel against intrenched or bureaucratic groups. Many of you know how they resist even strongly centralized departments of public instruction, and how the effectiveness of such departments may be jeopardized and much lessened by the very perfectness of their organization; and if they were to engage in a custom of extraneous forms of news-giving in the public press, the resentment would be the greater. In our rural work, we are in danger of developing a piece of machinery founded on our fundamental industry; and if this ever comes about, we shall find the people organizing to resist it.

Of course, we want governments to be efficient with funds and in the control of affairs, but we must not overlook the larger issues. In all this new rural effort, we should maintain the spirit of team-work and of co-action, and not make the mistake of depending too much on the routine of centralized control.

In this country we are much criticized for the cost of government and for the supposed control of affairs by monopoly. The cost is undoubtedly too great, but it is the price we pay for the satisfaction of using democratic forms. As to the other disability, let us consider that society lies between two dangers—the danger of monopoly and the danger of bureaucracy. On the one side is the control of the necessities of life by commercial organization. On the other side, is the control of the necessities of life, and even of life itself, by intrenched groups that ostensibly represent the people and which it may be impossible to dislodge. Here are the

Scylla and the Charybdis between which human society must pick its devious way.

Both are evil. Of the two, monopoly may be the lesser: it may be more easily brought under control; it tends to be more progressive; it extends less far; it may be the less hateful. They are only two expressions of one thing, one possibly worse than the other. Probably there are peoples who pride themselves on more or less complete escape from monopoly who are nevertheless suffering from the most deadening bureaucracy—the insistence on mere governmental accuracy and efficiency.

Agriculture is in the foundation of the political, economic and social structure. If we can not develop starting-power in the background people, we can not maintain it elsewhere. The greatness of all this rural work is to lie in the results and not in the methods that absorb so much of our energy. If agriculture can not be democratic, then there is no democracy.

L. H. BAILEY

MICROBIAL ASSOCIATIONS¹

SOCIOLOGY, as it is generally conceived, conveys a knowledge of the human as a social and ethical creature and maintains for him an harmonious relation to his social environment, as well as considers human society in its ensemble. As an individual, man's composite is different from what it is as a social factor. His attitude toward self is not his attitude toward society at large. Perhaps primitive man was concerned with self only, but with the development of society this limitation was not possible. Man, as he at present exists, has multiplied his individual and social functions. He has developed highly ethical relationships. Under existing conditions, too, he would be wholly helpless without his social ties.

¹ Address of the president, Society of American Bacteriologists.

To the biologist, this situation with man, aside from his ethical nature, may be regarded in large measure as material, biological, and may be pertinently designated as special functional development. To the human sociologist, however, the avenue of approach is through the human as a transcendent being in possession of other characteristics than material, and in no sense an animal, but a creature divested of brutish instincts. The spiritual is given command over material functioning. Biological materialism apparently yields to the enshrouding and directing forces of humanism or human ethics. Notwithstanding, the biologist feels and beholds as such a sociology of plants and animals that is very similar, and, furthermore, he sees written in their histories and associations most of the directive agencies operative in human society, only with less ethical exaltation.

This larger sociology, for such it is if we study human sociology biologically as well as through its superficial subjective manifestations, has much interest which is of useful significance. It would not be so difficult to establish parallelisms and expressions of man as an animal in every field of biology, if that were our object. This would, moreover, be a comparative study which can not occupy our attention, for it would lead us far from our purposes. The microbial world, our own province of study, offers itself for specific consideration and is of peculiar and paramount interest to a microbiologist. The possible extensive field of biological sociology just hinted at is used rather to open our minds for the possibilities contained therein.

The microbe, by itself or in pure culture, is only one phase of its existence. In company with other species quite another phase is presented, and this is determined by the associated species and by the many conditions under which these associations may be

found. Variations and multiplications in functions instituted by these associations, with the resulting products, must influence in the course of time the actual nature of the organism. Its morphology, culture and physiology must assume new aspects, for this accords, by analogy, with recognized laws of environment. If the highly developed molecular, protoplasmic complex is sensitized, some fractional group or radical thereof must yield its claim to some other of superior affinity, which in turn will manifest its presence in all probability either morphologically, culturally or functionally.

Therefore, to suggest merely the richness of a human sociology, a sociology of plants and of animals, and a sociology of micro-organisms in a parallelism, fits the mind for the reception of the general principles involved and their projections into the larger field. It prepares the listener to read in fullness between the lines unwritten developments and unwritten biological laws expressed and observed in all living forms.

Humanists rightly call the social treatment sociology, but were we to mention plant and animal sociology and microbial sociology, too much may be injected for human euphony and it may be misleading. For our purposes, microbial associations are sufficiently inclusive and represent many conditions of living together. This is done advisedly, notwithstanding the common usage of the term "symbiosis," which, according to Minchin, should be applied in a restricted sense to mutual advantages on the part of each symbiont involved. Difficulties are therefore avoided by circumvention.

In Frank's treatment² of the biological relationships his attitude is clearly revealed

by his approach and classification. His parasite depends upon another for nutrition, but the other relationships as the ivy and tree, and the mite and its hosts, as well as De Bary's³ fungus and alga in mycetozoa, indicate only some of the more apparent biological associations. They record observations without knowledge and demonstration, without research and logical deductions. They are of the order which rank among pioneer scientific effort. Like superficial surveys, they were simply seen and recorded and have been the means of making it possible for a historical, consecutive development. Frank admitted a classification, but, laboring as he did in ignorance of the many facts which have come to light since his time, his classification seems impertinent. Others even later than this, as De Bary, Hansen, Wortmann and Berlese, would have included insects in the carrying of pollen from flower to flower, or yeasts in the starting of fermentation changes, as types of distinctive association.

Probably the first tangible knowledge of *microbial associations* may be traced to Pasteur. It may be that this "Parent of Microbiology" was not fully conscious of the significance of associations, although his work with anaerobic organisms, acetic organisms and brewing organisms must have conveyed an impression which made his mind receptive to other possibilities. There was an inference apparent in nearly all the early work—that some single species was wholly responsible for every recognized process of fermentation or disease. The emphasis thus given to pure cultures has doubtless been the means of minimizing the force and importance of mixed cultures; for has it not been a common experience of workers to witness persistent efforts in securing results by means of pure cultures

² A. B. Frank, *Bett. u. Biol. d. Pflanz.*, Bd. 2, S. 123, 129.

³ De Bary, "Comp. Morph. and Biol. of Mycetozoa and Bacteria."

from processes which were wholly complex and dependent upon an association of organisms? These intimate interrelations of microorganisms have in a degree been overlooked or neglected because of their complexity.

Garré⁴ suggested that one organism may prepare the food for another by changing the medium upon which it may be growing. It is true that this had been demonstrated some years before, by Pasteur and others, but had scarcely been approached in this manner. Marshall Ward⁵ added to the knowledge of the world by his studies on ginger beer. The results secured penetrated the heart of the matter and made the suspicions and facts regarding associations replete with a new meaning and value. The Japanese "sake," or rice wine, furnished an example of sequence which too extended the horizon of the nature of fermentations. The milk preparations, koumiss, kephir and many others, did not yield readily to pure culture treatment if gauged by the native products, and accordingly forced the notion of mixed cultures.

Such findings in fermentations coupled with ideas which had been advanced by botanists, as Frank, gave to bacteriological association deeper significance than had been anticipated by the earlier workers. Knowledge had progressed from loose associational relationships through the morphological to the functional aspect of association, as hinted by Garré. Now if functional, as nutrition, is to be interpreted in terms of physics and chemistry, then the basis of attack is at once affirmed. Pfeffer⁶ intimated some such foundation when he advanced two classes, "Conjunctive Symbiosis," in which the functioning of one is

essential to the functioning of the other—parasitism; and "Disjunctive Symbiosis," in which there is more or less independence; nevertheless, this companionship may be favorable or antagonistic. Out of these, there have apparently emerged with some definiteness "symbiosis," "metabiosis" and "antibiosis," terms familiar to every microbiologist, but not open to exact interpretation.

Pfeffer's classification provided an excellent beginning for associational studies. Whether the term "symbiosis" is satisfactory in his classification depends largely upon individual understanding. It has seemed to me that "association" would be better fitted for the place occupied by "symbiosis," and the "symbiosis" be reserved for a subclass in which a very intimate interdependable relationship exists. Apart from this, I shall follow the division of Pfeffer in our discussion.

In an effort to conform to these general classes of Pfeffer's, it is expedient to subdivide for detailed consideration, since the idea of conjunctive association branches into divers paths and disjunctive association may include many loose relationships.

Auto-relationships or those self-associations, as a class of conjunctive associations which arise from growth and multiplication, are peculiarly suggestive, for they are commonly observed in the laboratory. Organisms will flourish and grow within limitations only upon an ordinary medium, and in the natural changes as fermentations and diseases occurring outside of the laboratory, away from artificial influences, the same phenomena are observable. Buchner⁷ and Carnot⁸ have claimed that the cholera bacillus and tubercle bacillus find more favorable growth in cultures containing

their products. On the other hand, Duclaux⁹ believes that an organism becomes less vigorous when its growth is continued upon media in which some of its products exist. Thibaut,¹⁰ LeSage¹¹ and Nikitinsky,¹² have studied auto-association. Their results however do not lead to the same conclusions, although they are explicable and constant. There is to be found from Thibaut a suggestion that the existence of fermentation products favors growth of yeasts. *Penicillium* grown on its own culture does not reach fructification, says LeSage. Then, too, Nikitinsky found favoring conditions when molds are cultivated upon media containing their own products. He noticed as well that antagonistic influences are manifested if the media contain certain carbonaceous substances, even stating that in the presence of carbonaceous foods, probably lactic acid, butyric acid and alcohol are at times responsible for stimulation or retardation. Wildier¹³ has introduced the "Bios Fraga." Contrary to the views of Pasteur, he claims that minute quantities of yeast will not grow in the medium of yeast ash, ammonium salts and some sugar. He contends that the element introduced by the addition of greater amounts of yeast for inoculable material is required. He also says that it is a substance very soluble in water, dialyzable, difficult to alter or precipitate, and is found no longer after incineration. It is a substance which exists in small quantities and is indispensable. To this is attached a sort of mysticism which would lead one to

recognize some hidden guard within the impregnable fortress of life.

In infectious diseases, there are indications of self-curbing or restrictive development. There appear to be some influences acting in the cases of many pathogens. For instance, the organisms which give rise to influenza, whooping cough and measles and others run their courses; they have their rise and reach their maximum stage of development, and then decline in their activity. Others, as tuberculosis and glanders, appear to be accelerated by their extended development in the body. Again, there is the type which may be designated in general by organisms which are transmitted through carriers or are commensals. Whether an organism reacts upon itself through its growth in media which are fermentable, or in the body of an animal where disease is produced, or where the body acts only as a carrier, is it not possible to discern a common functional principle responsible?

Conjunctive association seems also to designate another subclass which, for the time being, may be called "serial association." One species seems to follow upon the heels of another in point of time, and is dependent upon the other for its life and activity. Sometimes these species appear to grow together simultaneously, but in nearly every case the life and activity of the one depends in sequence upon the life and activity of the other. One seems to be the leader and the other the dependent. There are instances, perhaps, where the relationship between the two suggest an interdependence. In this case, both may be leaders and both dependents. I do not know of a case that has been worked out in detail confirming this peculiar relationship, although observation may suggest it. It may be assumed that in such a case products which are favorable to each are

simultaneously created. Where one follows the other, relying upon association products, many illustrations are available.

Ammonification in the soil usually asserts that protein material has undergone change, yielding a series of products by the action of specific classes of organisms. It is known that sometimes in this series more than one class of organisms is involved. After ammonia is produced, the common oxidation processes resulting in nitrites and nitrates are effected by two distinct classes. Accordingly, in the disintegration of a protein molecule by microorganisms, there are probably several classes involved in the process, each in consecutive order. All of them are dependent one upon the other in the various steps of the degradation of the molecule. Then again, if we were to consider the reduction of nitrates to nitrites to nitrogen or ammonium, there are two or three other classes, each waiting its turn in the serial change.

The different stages in the ordinary decomposition of milk speak of this same dependence. At first the several types in milk appear to foster the development of the lactic organisms; following in the wake of the lactic organisms are those which neutralize and then those which cause proteolytic changes; and if we were to trace out the reduction of the complex substances to the various simple mineral constituents that may be found in the final product, there would doubtless be other classes, similar to those found in the mineralizing actions of the soil.

In fermentations, too, are well-known examples: the change of apple must to apple wine, from apple wine to vinegar by yeast and acetic bacteria; the production of ginger beer with a specific yeast and specific bacterium; the making of "Sake" from rice by means of a mold and a yeast; as well as other well-known fermentations in

nature, all of which confirm how frequently the life of one organism is dependent upon the life of another. Among the pathogens and those organisms associated with the animal body are many striking instances. The many complications illustrate the possibilities of interdependence—sepsis following scarlet fever and typhoid fever, diphtheria and pest; pneumonia following influenza and tuberculosis; gangrene streptococci with certain anaerobic putrefying organisms; pyogenic bacteria and tetanus organisms. We can not be as certain perhaps and as distinctly satisfied as in the fermentations, the nature of which is so well known, that one product follows another and definitely in the order mentioned, but that there is a decided influence manifest can not be gainsaid. When growing together under circumstances of association, the disease is usually aggravated, or one organism appears to pave the way for another. It is a kind of serial relationship which parallels very closely, to say the least, those which we find in fermentations.

This serial dependence is not lost even where host and parasite are concerned. The tick and the cow are indispensable to the piroplasma in the corpuscle; the fly and the antelope to the trypanosoma in sleeping sickness; the mosquito and man to the plasmodium in malaria; the bacterial forms and man to the ameba in his intestines; the rabbit and some outside habitat to the coccidium. The microorganisms involved in these cases are apparently dependent upon the metazoa concerned for their growth and cyclic development, very much as the nitric organisms are dependent upon the products produced by the serial changes in the breaking down of the protein molecules. In these cases in which animals furnish the material for the life of microorganisms, difficulties are found in the determination of the required condi-

tions and immunity factors of the animal, because of the limitations in knowledge. Is it not fair to suppose, however, that this required material may be just as definite, and may occupy in many cases the same relationship to the organism as in the case of fermentation?

Going a little higher in the scale of life for a single illustration, Keeble¹⁴ contributes an interesting study of association in *Convolvula roscoffensis*.

In its earlier youth *Convolvula roscoffensis* feeds after the manner of animals in general, on other plants and animals. This is the first stage. In the course thereof green cells appear in the body, increase, multiply, photo-synthesize and distribute food material to the animal tissues. For a while, *Convolvula roscoffensis* receives food from two sources—from ingested plants and animals and from its green cells. This second phase is succeeded by a third in which *Convolvula roscoffensis*, having ceased to ingest solid food, is nourished in the same manner as the colorless non-chlorophyllous tissues of a green plant are nourished, by the products of the photosynthetic activity of its green cells. The last stage of all which ends this strange eventful history: The animal digests its green cells, and having done so dies. In the first phase the mode of nutrition is animal-wise; in the second, part animal, part plant-wise; in the third, altogether plant-wise or holophytic, and in the fourth auto-trophic, that is by living on itself.

Interesting cases of animals and plants higher in the scale than microorganisms can be easily multiplied.

The strenuous efforts of the laboratory worker to find a medium for pure culture studies seem to be provided in nature for many organisms. What appears laborious and complex to us in our artificial attempts is simple and direct as a natural process. Oftentimes associated products suggest the missing compound for pure culture operations, as has been experienced so often, but this frequently fails quantitatively or

qualitatively through some neglected or undiscovered by-product.

In Pfeffer's diazunctive symbiosis many possibilities exist, but whether they may be regarded as a true biological association, or by analysis may be included in his conjunctive symbiosis, remains an open question.

Keeble's plant animals can be regarded as independent in a sense, but, on the other hand, they are very dependent. So too, the poled lima bean needs support which may in no manner be considered a part of its metabolism. For its best development the ivy needs a tree or stone wall; still, they are not biologically related. Because a streptococcus may accompany diphtheria infections and produce complications, or the tetanus organism is found in pyogenic processes, it does not follow that diphtheria is dependent upon streptococci or that the pyogenic organisms are dependent upon tetanus organisms, to appear in the pure individual life. That these processes may be modified or that these organisms of diphtheria and tetanus are perhaps fostered by association, will not be contradicted; yet they may live as independent forms. The pertinency of this class, therefore, must find its answer in physiological dependency or social independence with favoring or antagonistic elements.

If associations of microorganisms dependent or otherwise are subjected to analysis, there may be traced through them all some functional factor or principle as temperature, oxygen supply, food supply or condition of food (whether acid or alkaline, whether dry or moist, whether composed of one class of elements or another), or the production of metabolic products. For instance, the oxygen requirements may be illustrated by the growth of *Clostridium butyricum* in the presence of aerobic organisms; moisture by the elimination of many

¹⁴ Keeble, F., "Plant-Animals—A Study of Symbiosis," Cambridge Press.

bacteria in a mixed culture composed of brine, and the persistence of cocci and torule; food by the feeding of ameba bacterially or acetic organisms with alcohol; reaction by the development of the lactic organisms in milk and the eradication of its associates; temperature by a combination in the growth of tubercle bacilli with saprophytes which will not grow at moderate temperature. Those fundamental biological requirements favor some forms of life association, while antagonizing others. Taken in conjunction with metabolic products as alcohol, lactic acid, acetic acid, amino-acids, ammonium, toxins and the many others that are possible, these biological factors offer a wide range of association, and at the same time determine the limitations.

Our experiences support these views, for involution forms or distorted morphology is easily traceable to one or more factors mentioned, and in the functioning processes of microorganisms how easy it is to alter the metabolic products and even the form by the addition or omission of an element. These acts have become an unconscious procedure and we do not, as a rule, make the subject one of systematic inquiry.

The association of animal and animal, or animal and plant, or plant and plant, when carried to comparatively loose social relations will in large part support this interpretation of these more intimate associations, illustrated through the channel of microorganisms. Animal life becomes adjusted to certain plants or other animal life, and is dependent upon their existence; plants depend upon animals and other plants; into which social relations enter the factors of food, temperature, and the other life conditions which apply to all living forms. Since this seems a fact so well established, and our work as microbiologists leads into the affairs of so many organisms

which instigate numerous diverse changes—changes in some instances which are instituted by associational growth and which may affect their morphology, culture and physiology—it is pertinent in our researches to consider an organism in its natural microbial associations as significant as in a laboratory pure culture. Such factors should be directive for purposes of identification, study and application, since they suggest those possibilities which may be bound up in the intra- and inter-molecular relationships and reactions that dominate associations and individuals.

CHARLES E. MARSHALL

MASSACHUSETTS AGRICULTURAL COLLEGE,
AMHERST, MASS.

DR. A. F. A. KING ON MOSQUITOES AND
MALARIA¹

MUCH as I might wish to write of Dr. King as a personal friend, as a great teacher, as a big, broad, warm-hearted human, in all of which rôles I knew him well, it has seemed best to your committee that I should confine my consideration to the single episode in the career of this many-sided man which relates to mosquitoes and malaria.

Dr. King was a deep thinker. He was not satisfied with even the generally accepted and apparently well founded views of men of science and of his own profession without a careful consideration and an ingenious twisting and testing of argument. This quality of mind he showed in a marked degree during the years 1881 and 1882 when he was filled with the thoughts of malaria and its probable origin and transmission. He never told me how or when the idea came to him that mosquitoes were transmitters of this disease. His search of the literature probably followed a fairly well worked out argument originating in his own mind. Surely he considered the idea as original when he came, probably late in 1881, to the laboratory of the late

¹ Read at the memorial meeting for Dr. A. F. A. King of the Medical Society of the District of Columbia, Washington, January 20, 1915.

Dr. C. V. Riley, my former chief and predecessor in office, and talked over the idea with Riley and myself. Shame to the short-sightedness of the two of us, that we rather scouted the idea, while giving him the information on mosquito biology which he afterwards incorporated in paragraph No. 1 of his published brief.

His argument was fully elaborated and his full paper was prepared early in 1882 and was read before the Philosophical Society of Washington, February 10 of that year, under the title "The Prevention of Malarial Disease Illustrating *inter alia* the Conservative Function of Ague." This meeting of the Philosophical Society was attended by forty-two members and visitors, and Dr. King's paper was discussed by Dr. J. S. Billings, Professor Doodittle, Dr. Toner and Dr. Antisell. No record was made of what was said in discussion except the following:

Mr. Billings remarked that since ague did not invariably result from insect bites, the most that could be claimed was that they accomplished an accidental inoculation with malarial poison.²

This statement is rather ambiguous and does not indicate what Dr. Billings really thought of Dr. King's paper.

The paper in its full form was never published, but in *The Popular Science Monthly* for September, 1883, Vol. XXIII, pages 644-658, appears an article entitled "Insects and Disease—Mosquitoes and Malaria," which in a footnote is said to have been an abstract of the Philosophical Society paper. It is upon this published abstract that the scientific world's knowledge of King's views is based. Since the discussion in Riley's office, he had made a careful study of the literature and had found references to several early suggestions as to the possible carriage of disease by insects or as to the cause of disease by insect bites. His arguments are displayed in connection with nineteen propositions or series of facts with regard to the so-called malarial

poison. These facts were derived from different sources, but most of them were quoted from a paper read by Dr. John T. Metcalf, United States Sanitary Commission, 1862. Not all of these nineteen paragraphs are of equal force; and it has become the custom of writers in referring to King's paper to reduce them practically to the following:

1. The malarial season corresponds to the season of mosquito abundance.

2. Malarial country is suitable for mosquito breeding.

3. Similar conditions afford protection against malaria and against mosquitoes.

4. Exposure to night air means exposure to mosquitoes.

5. Influence of occupation. Soldiers, tramps and fishermen are particularly susceptible to malaria and are especially exposed to mosquitoes at night.

6. Turning up the soil or making excavations in previously healthy districts is often followed by malaria, but this turning up of the soil gives opportunities for water to accumulate and thus for mosquitoes to breed.

7. Coincidence of malaria and mosquito abundance—increase of both in late summer and early autumn.

But this summary gives but a faint idea of the value of *The Popular Science Monthly* paper. The reasoning throughout is close and convincing, and additional important points are brought out. For example,

"Malaria has an affinity for dense foliage, which has the power of accumulating it when lying in the course of winds blowing from malarious localities," and mosquitoes accumulate in and are obstructed by forests and trees.

Again,

"In proportion as countries previously malarious are cleared up and thickly settled, periodical fevers disappear."

Here he points out that in such cases the land is cultivated and its swamps and pools are drained so that mosquito-breeding places are abolished. He further states that as the forests and underbrush disappear before the implements of the agriculturist colonies of

² *Bulletin of the Philosophical Society of Washington*, Vol. VI. (containing the minutes of the society for the year 1883, etc.), published 1884, page 10.

mosquitoes wafted by winds are not obstructed and are accumulated by foliage. Again, the fact that malaria usually keeps near the surface of the earth and is said to "hug the ground" or "love the ground" corresponds once more to the habits of mosquitoes.

It will be unnecessary to take up any of the further points, except to quote two significant paragraphs as follows:

In opposition to the mosquitul origin of malarial disease it is known that numerous mosquito wounds may be inflicted without the occurrence of malarial disease; but this is by no means incompatible with the theory. We do not yet know whether the poison be mosquitul saliva or whether the fever-producing element be a bacillus with which the puncturing proboscis of the insect may be loaded at the time of inflicting its wounds. The scratch of a lancet will not produce vaccinia unless the instrument be charged with vaccine matter; the puncture-needles of Pasteur would be harmless and impotent, did he not load them with infecting bacteria; so with dog-bites and hydrophobia, etc.

Again:

Nay, it may even turn out that, under certain circumstances, mosquito-bites shall even be protective against malarial disease, for as Pasteur and others are able to produce, artificially, "attenuated culture-fluids," the inoculation of which, while producing slight symptoms, protects from more serious phases of disease, so may there exist in nature naturally "attenuated" fever-poison fluids, the inoculation of which, by mosquitul puncture, may produce trivial symptoms, and thus protect from more decided attacks of veritable fever.

In the first of these paragraphs Dr. King fully meets the objection which curiously enough is raised to-day in the Bitter Root Valley in Montana by the inhabitants who claim to disbelieve the so-called theory of the tick-transmission of the Rocky Mountain spotted fever. "Why," they say, "We have been bitten by ticks many times and have never had the fever." As King pointed out in these early days, they have not been bitten by an infected tick.

In the second paragraph he almost anticipates Koch's conclusions as to the immunity

of native children in German East Africa, even though he does not point out their danger as reservoirs.

It may be well to quote still another paragraph which is of especial significance:

In so far, therefore, as regards the geographical relation between mosquitoes and malarial disease, it may be said: (1) The two often coexist; (2) there is no decided proof that localities alleged to be exempt from ague are also exempt from mosquitoes; (3) there is no locality noted for malarial disease where mosquitoes do not exist.

Very naturally, in conclusion, the far-sighted author mentions the question of prophylaxis on the basis of his theory. He points out protection to the individual during the evening and night by gauze curtains, window-screens or clothing impenetrable to their probosces, or an anointment of the body with some liniment; protection to the domicile by screens or fences, or light traps, or the use of smoke such as pyrethrum, or of a volatile oil; municipal protection by the destruction or draining of swamps and pools, etc.

It will thus be seen that malarial prophylaxis has made practically only one step since the days of King, except in so far as measures are concerned which depend upon the now known biological peculiarities of malarial species. His system included everything which was done in Italy for many years after Ross's discovery and which resulted in the lowering of the percentage of malaria on the Roman Campagna from 74 to 14, and his only omission from the present system is that of quinization of the people at large as practised by Koch in East Africa and by the late Dr. Celli and his colleagues in Italy to-day.

It is strange that so suggestive a paper as this and, in fact, one so theoretically conclusive, should have been received with so little interest and have been so soon forgotten. That Dr. King was a strong man is shown by the fact that he was not in the least discouraged by his interview with so renowned an entomologist as Riley, or by the lukewarm interest with which his original paper was received by the Philosophical Society of Wash-

ington, but went on and prepared it in its final form for publication in *The Popular Science Monthly*.

There was little published comment, and it was not until 1899, sixteen years later, that Dr. Geo. H. F. Nuttall, now of Cambridge University, England, in his classical paper "On the Role of Insects, Arachnids and Myriapods as Carriers in the Spread of Bacterial and Parasitic Diseases of Man and Animals—A Critical and Historical Study," published as one of the Johns Hopkins Hospital Reports, Vol. VIII., Nos. 1 and 2, that the full force of King's argument began to be appreciated. Nuttall here incorporated practically all of King's arguments and added many data gathered from other writers as well as his own, and, as he has since publicly stated and as he has personally remarked to me, it is remarkable that the 1883 paper was not soon followed by critical investigation. As has been shown so many times since, however, and strikingly in the case of Sambon's insistent claims for the carriage of pellagra by *Simulium*, a theory in no way comparing to King's for the soundness of its basis, conclusions based on epidemiological findings or upon coincidences are always dangerous. Where the range of a suspected host coincides with the range of a disease, it is possible or even probable that the suspected host may have some relation to the disease, but of course transmission experiments are necessary for absolutely definite conclusions.

And so it happened that, apparently without knowledge of King's paper, but based upon his own work in the transmission of filariasis by *Culex* and upon the then recognized transmission of the causative organism of Texas fever of cattle (sometimes called bovine malaria) by a tick as demonstrated by Smith and Kilbourne, Manson suggested to Ross the necessity for accurate laboratory work on malaria with mosquitoes as possible hosts. How triumphantly Ross carried out this magnificent piece of research is known to all the world, but it is a pity that it had not been done years earlier. Of course the laboratory technique in 1883 was not what it was in 1897,

and of course, although Laveran had already discovered the *Plasmodium malariae*, practically nothing was known of its life-cycle in 1883, but is it not possible, indeed is it not probable, that, had our fellow member, Doctor King, possessed the laboratory facilities and the technique at the time when he was so full of his great idea, he would have solved the problem, would have confirmed his anticipations, would ultimately have received the Nobel prize, and would have gone down to history as one of the greatest benefactors of the human race?

L. O. HOWARD

U. S. DEPARTMENT OF AGRICULTURE

THE COMMITTEE OF ONE HUNDRED ON
SCIENTIFIC RESEARCH OF THE AMERICAN
ASSOCIATION FOR THE
ADVANCEMENT OF
SCIENCE

The committee held its second meeting in Houston Hall, the University of Pennsylvania, Philadelphia, on the afternoon of December 28, 1914. Mr. Pickering was in the chair, and the other members present were:

Messrs. E. W. Brown, Franz Boas, J. McK. Cattell, A. D. Cole, Edwin G. Conklin, Chas. R. Cross, Chas. B. Davenport, H. L. Fairchild, Karl E. Guthe, Ross G. Harrison, L. O. Howard, George E. Hulett, Chas. S. Howe, W. J. Humphreys, W. W. Keen, Frank R. Lillie, D. T. MacDougal, C. F. Marvin, C. L. Mees, George T. Moore, T. H. Morgan, Herbert V. Neal, Edward L. Nichols, E. B. Ross, Wm. T. Sedgwick, Frank Schlesinger, Edgar F. Smith, Henry B. Ward and Arthur G. Webster.

After a statement by the secretary and introductory remarks by the chairman, the committee listened to reports from the subcommittees on research funds, on research in educational institutions, on the selection and training of men for research, on the promotion of appreciation of research and on plans for the subcommittee on research in industrial laboratories. Each of the reports was fully discussed, most of the members of the committee in attendance participating.

On the recommendation of the executive

committee or on motion, action was taken as follows:

1. Mr. Charles R. Cross was made chairman of the subcommittee on research funds, to fill the vacancy caused by the death of Charles Sedgwick Minot. Mr. W. B. Cannon has been appointed to fill the vacancy on the committee of one hundred.

2. The subcommittee on research in industrial laboratories was constituted to consist of Messrs. Raymond C. Bacon, C. L. Mees, M. C. Whitaker and W. R. Whitney.

3. A subcommittee on research under the national government was authorized with Mr. S. W. Stratton as chairman.

4. A subcommittee on research on the Pacific Coast was authorized with Mr. J. C. Merriam as chairman.

5. The executive committee was authorized to establish other subcommittees. Among those suggested and discussed were committees on research institutions, on research in museums, research under municipalities, research in the south, research by agencies promoting the public health and the publication of research.

6. The committee adjourned to meet with the American Association for the Advancement of Science at Columbus, Ohio, on the afternoon of Monday, December 27, 1915.

There are appended the opening remarks of the chairman of the executive committee and reports from the four subcommittees.

J. McK. CATTELL,
Secretary

SCIENTIFIC RESEARCH: INTRODUCTORY REMARKS BY THE CHAIRMAN

Several persons have asked the question "What can be accomplished by the Committee of One Hundred on Scientific Research?" To answer this question, we must first ask, what is the present condition of the United States as regards scientific work of the highest grade, and what means are at present available? Six years ago from a study of the men recognized as eminent by the great scientific societies of the world, it appeared that the number selected from the United States was six, the same as from Saxony. The ratio of the populations is about twenty to one. Of the Americans thus selected no one devoted much, if any, of his time to teaching, and three were born outside of the United States.

The government of the United States expends an

enormous sum each year in scientific research. In the departments of science best known to me, a portion only of this amount is spent wisely. Certain of the states and cities also appropriate large sums, a part of which may be regarded as devoted to research.

At the last meeting of this committee the results attained by the research laboratories of the great industrial corporations was brought out in a striking manner. It was shown that they were not restricted to commercial results, and that friendly relations existed between them. A single successful research might here easily repay the entire expenditure.

The universities of the country devote vast sums to the diffusion of knowledge, but their contributions to its extension are comparatively limited. They expend large sums entrusted to them with the condition that it shall be used for original research, and valuable results are also obtained by their officers in their own time. The proportion of the entire funds which is devoted to research is, however, exceedingly small. There are few universities which could appropriate money for research, apart from teaching, for instance, to supply an officer with an instrument, an assistant, or money for publication. The general public do not realize this; they think that since the universities teach science, they add to it, as well as diffuse it. Research receives but little aid from the numerous unrestricted gifts to universities. If a tenth of the money used for teaching were employed in research, Americans would soon take their proper places among the great men of science of the world.

Certain institutions like those established by Rockefeller and Carnegie have devoted large sums of money to research along particular lines, but having no especial relations with other investigators.

None of the methods so far described help the man of genius in his home or in his laboratory, none of them "seek the particular man, and aid him." The research funds are the only means for supplying these needs. Unfortunately, their total income is small, but some of them have a very remarkable history. For instance, the Elizabeth Thompson Fund has an annual income of about a thousand dollars, but largely through the eminent skill of our late fellow member, Charles S. Minot, during quarter of a century it has aided 169 researches, with only five failures. A large part of these could not have been completed without this aid. The grants have been distributed throughout

the world and have aided nearly every department of human knowledge. Similar results in a narrower field have been reached by the Rumford Fund. By such funds as these, administered by local committees, it is probable that greater advances in pure science can be obtained for a given outlay than in any other way. An attempt has been made to furnish a concrete example.

Astronomy has been more favored than any other science in receiving large gifts for its support, and it is through these that America occupies its present honorable place in astrophysics. As a consequence, observatories are carefully organized and great results can be obtained from a moderate expenditure. Recently I wrote to twelve leading astronomers, asking each how he would expend a moderate sum.¹ The unexpected reply was that, in almost every case, the greatest need was for an assistant. In many cases, a small sum would thus double the output of an observatory.

It is obvious that each of the problems here considered suggests a field of work for this committee, at first through subcommittees accumulating facts and then if possible improving the conditions. We shall this afternoon see that a good beginning has already been made.

REPORT OF THE SUBCOMMITTEE ON RESEARCH FUNDS

The fact that the members of the subcommittee on research funds reside in places remote from one another has made it impracticable since its appointment in April, 1914, to hold formal meetings, but several meetings of an informal character for consultation and debate have taken place among those who could be assembled. At only one of these, however, have they had the benefit of the counsel and advice of Dr. Minot, the chairman, since his illness followed by death occurred before any work could begin in the autumn.

It seemed to the subcommittee that a most obvious manner in which at the beginning, it could aid the work for which the Committee of One Hundred was instituted would be to enter, if possible, into communication with those having the charge of the various funds in this country which are available for purposes of scientific research, so that there might be a wider knowledge than at present exists as to the range of application of the several funds and of the researches in progress with aid from any one or more of them. With this knowledge, in case of the receipt of meritorious applications for aid by the trustees of any

particular fund which they were unable to grant or which might seem to come especially within the scope of some other research fund, the trustees thus applied to could refer such applications to those in charge of such other fund should they think it advisable. With this end in view, the following letter was sent to the chairmen of the trustees or committees in charge of a number of representative research funds.

Dear Sir: At a meeting of the "Committee of One Hundred on Scientific Research" of the American Association for the Advancement of Science held at Washington, April 20, 1914, several subcommittees on Research Funds, was constituted as follows: Charles S. Minot, chairman, Simon Flexner, E. C. Pickering, R. S. Woodward, Charles R. Cross, secretary. The recent illness and death of Dr. Minot have deprived the subcommittee of his inestimable services.

It is felt that this subcommittee may perhaps aid in the furtherance of research if it can bring about relations of correspondence among those in charge of the various research funds existing in this country, whereby scientific workers who need aid in the prosecution of their researches may be directed to the sources from which such help is most likely to be obtained. This has been done informally in a number of instances in the past, and the experience thus gained has suggested the belief that some definite plan of cooperation would be useful.

For this it would be desirable that the subcommittee on research funds should have a record of the several existing funds, the amount of each, the approximate annual income from each, the objects to which they are devoted, the conditions under which they are available, and the grants already made for researches still in progress. Frequently such information is already to be found in published form. With this at hand, the committee could refer suitable applicants to the officers in charge of such particular funds as in its judgment might appropriately consider the matter.

The committee, of course, would neither expect nor desire that any portion of the authority or responsibility of the trustees of any research fund should be delegated to it. Its function would only be to act as a sort of clearing house, as it were, which could to some extent classify and distribute applications for aid to the most available sources. Such a procedure would in no way obligate the managers of any funds to grant aid to any person unless they should believe that they themselves would have been ready to do so upon their own initiative.

It seems to be the case that many younger scientific men who are engaged in the prosecution of meritorious researches are not aware of the existence of certain of the research funds, and still less of the purposes to which they may be applied. Such a committee as that appointed by the American Association for the Advancement of Science, which would soon become generally known, might, it would seem, be of value to all such.

Will you kindly inform the undersigned whether

¹ See SCIENCE, Vol. XLII, p. 32.

such suggestions as have been made in this letter meet with your approval, and whether you would be willing to join in such collaboration as has been outlined. And furthermore, if you are favorably disposed toward such action as that outlined in this letter, this committee would be glad to know whether you have at present any applications for grants for research which you care to send to it for consideration.

An early reply will be appreciated in order that as complete a report of progress as is possible may be made to the American Association at its forthcoming meeting in Philadelphia.

I am

Yours respectfully,

CHARLES R. CROSS,
*Secretary of the Subcommittee
on Research Funds*

The replies received express approbation of the plan set forth in the letter and indicate a willingness to undertake such an intercommunication of information as the letter suggests.

CHARLES R. CROSS,
Secretary

SUBCOMMITTEE ON THE SELECTION AND TRAINING OF STUDENTS FOR RESEARCH

In presenting a report from the subcommittee on the selection and training of students for research Professor E. W. Brown regretted that owing to his absence until November very little had been done. He gave, however, a brief account of some of the ideas which the subcommittee had in mind. One of the chief questions raised has been whether the chief effort should not be made towards improving the facilities for the able men in their undergraduate work. In two or three of the American universities special courses have been established for such men and it is proposed to find out how much development has taken place in this direction and what success has been achieved so far. The subcommittee also proposes to find out the methods used in other countries to advance the interests of the able students. Various methods have been planned to achieve this object: amongst them separate instruction, extra work, less teaching in the classroom and more work expected outside, the recognition of scholarship in various ways and more specialization in one or two particular subjects have been suggested. In the discussion which followed some valuable suggestions were made. It was pointed out that in some subjects far too much assistance was given to the students, and consequently their faculties are not properly developed. It was proposed that some effort should be made in the direction of inducing graduate students to go to some particular

university because of the excellence of the department in that university rather than on account of the money rewards which it might offer. The committee hopes to undertake investigation of these questions and to offer a report with suggestions in due time.

SUBCOMMITTEE ON RESEARCH IN EDUCATIONAL INSTITUTIONS

The chairman of the committee, Mr. Edward L. Nichols, made a report of progress. The committee had had two meetings, and through its secretary, Mr. J. McK. Cattell, had addressed letters individually written and signed to the executive heads of all institutions of higher education in the United States, some 600 in number. The letter made enquiry concerning the attitude of the institutions in the following respects: (1) In making appointments and promotions, what weight is given to scientific research and productive scholarship? (2) Is research a part of the work expected from instructors and professors, and, if so, how much of their time can be devoted to it? Replies had been received from most of the institutions and some of them were read to the committee. In general they emphasized the weight given to scientific research and productive scholarship in making appointments and promotions and stated that research work was regarded as part of the function of the institution and its instructors, but there was great variation in different institutions. The committee plans to prepare and publish an analysis of these letters. It hopes later to make enquiries in regard to the actual opportunities for research work in different institutions.

PROVISIONAL REPORT OF THE SUBCOMMITTEE ON THE PROMOTION OF APPRECIATION OF RESEARCH

Your committee believes that the main ideas which it desires to present are already familiar to those conversant with the situation. But the committee nevertheless believes that these ideas are so important as to need further reiteration and emphasis.

In the first place a marked distinction may be made between research concerning the fundamental laws, principles and phenomena of any given subject, on the one hand, and research aiming to apply these laws more efficiently to practical purposes on the other hand. Happily, research in applied science is being developed, each year in larger measure, on this side of the Atlantic. None the less, there is danger of our overlooking the first type of

investigation, which is really more important than the other, because principles can not be applied before they are understood.

Research in pure science, with which the committee is mainly concerned, may in turn be divided into two categories: first, the discovery of original ideas and new phenomena; and, secondly, the systematic elaboration of ideas already suggested. Investigation of the latter type demands, to be sure, a high quality of intellect and thoroughly competent training, or it may become worse than useless; but, given these things, its success is mainly dependent on efficient organization and adequate financial support. On the other hand, research of the former type (namely, that leading to the discovery of new ideas) demands not only intellect and training, but also initiative or genius; it can come only from an individual, and from an individual possessing intuition and insight far beyond those of the average man. Because of the extraordinary importance of new ideas, especial emphasis must, therefore, be laid upon finding and supporting brilliant individuals.

It is not within the province of your committee to discuss the question as to whether these would best be fostered by universities or by research institutions. Each may be of invaluable service in its own way, and it is highly probable that some men would work better in one atmosphere and others in the other. We believe, therefore, that it would be a mistake for either universities or unacademic establishments to obtain a monopoly of research.

The main point with which we are concerned is the question of finding the underrated, unusual man and seeing that he is appreciated and given opportunity in the place best fitted to develop his powers. It is probable that at present the university is the best hunting-ground for this purpose, because the investigators in our important research institutions are already well fostered. In our great American institutions of learning, much valuable research is even now being accomplished both by teachers and by students. Among these men there are certainly many who are especially worthy of additional opportunities—for, in most cases, additional opportunities are needed by the men who are to perform original work of a high order. The demands made upon the American teacher are often not too great for those whose main business it is to teach, but, both in hours of class work and of administrative routine, they are very often altogether excessive for him who ought to give his main energy to research.

We feel, therefore, that in order to encourage the original minds in America, there should be more research professorships and research assistantships of high grade, which would raise their holders above the worry and inefficiency caused by financial need. Your committee recognizes that in most, if not all, American institutions of learning the salaries of professors are too low to support adequately those who have families, and believes that the salaries should be large enough to enable the original man of high rank leading the normal life to give his whole time to research and not to be forced into pot-boiling distractions. We all know of specific cases of men of unusual ability who have reluctantly abandoned research in pure science because of legitimate financial necessity.

Moreover, the research professor should not only be given time and adequate salary, but should likewise be provided with such skilled, private assistants as he may need to bring his work to its full fruition, and should be allowed to choose from among the graduate students applying for guidance those whose ability promises to offer real service to science.

The finding of the really promising man (who must possess not only originality, but also sound judgment and intellectual honesty) is not easy, because it often involves the gift of prophecy on the part of the searcher. Nevertheless, it seems to us that all those in each of our larger institutions of learning who are really interested in research of the highest kind, either individually or grouped together as a voluntary committee, should keep their eyes open for persons possessing in high degree the happy combination of qualities desired, and should urge upon presidents and governing boards the importance of supporting these persons so as to make it possible for them to yield their best fruit in discovery. To some extent, of course, this is already done, but concerted action and greater emphasis are desirable.

We suggest also that those understanding the importance of investigation should emphasize this importance on every reasonable occasion, and endeavor to increase the appreciation of the people of America, even the cultivated section of which is often ignorant of the nature and value of scientific research. This can probably be accomplished most successfully by pointing out how much has resulted for the good of humanity from specific researches in the past, bearing in mind the profound statement of Francis Bacon: "There is much ground for hoping that there are still laid up in the womb of nature many secrets of excellent use, hav-

ing no affinity or parallelism with any thing that is now known, but lying entirely out of the beat of the imagination, which have not yet been found out. They too, no doubt, will some time or other, in the course and revolution of many ages, come to light of themselves, just as the others did; only by the method of which we are now treating they can be speedily and suddenly and simultaneously presented and anticipated."

These suggestions constitute the recommendation of this preliminary report.

E. H. MOORE

SCIENTIFIC NOTES AND NEWS

THE award of the Bruce Gold Medal of the Astronomical Society of the Pacific, for 1915, has been made to Dr. W. W. Campbell, director of the Lick Observatory, "for distinguished services to astronomy." Candidates for this medal are nominated annually by the directors of the Berlin, Greenwich, Paris, Harvard, Lick and Yerkes Observatories, and from these the medalist is elected by the directors of the society.

DR. JOHN C. BRANNER has submitted his resignation as president of Stanford University to take effect on July 31.

PROFESSOR G. O. SARS, professor of zoology in the University of Christiania, has been elected an honorary member in the Challenger Society.

AT the annual exercises of the American Museum of Safety, held in New York on February 10, the following medals were awarded: The *Scientific American* medal for the most efficient safety device invented within a certain number of years and exhibited at the museum, to the Shurloc Elevator Safety Company, Inc., New York; the Travelers' Insurance Company's medal for protecting the lives and limbs of workmen, to the Commonwealth Edison Company of Chicago; the Louis Livingston Seaman medal for progress and achievement in the promotion of hygiene and the mitigation of occupational disease, to Surgeon-General William C. Gorgas, U. S. A.;

the E. H. Harriman memorial medal to the American steam railroad which during the year has been the most successful in protecting the lives and health of its employees and of the public, to the New York Central Railroad; the Anthony N. Brady memorial medal to that American electric railway company which for the year of the award shall have done most to conserve the safety and health of the public and of its employees, to the Boston Elevated Railway Company.

THE National Committee on Mental Hygiene met in New York City on February 17 when officers were elected as follows: *President*, Dr. Lewellys F. Barker; *vice-presidents*, Dr. Charles W. Eliot and Dr. William H. Welch; *treasurer*, Otto T. Bannard; *medical director*, Dr. Thomas W. Salmon; *secretary*, Clifford W. Beers; *executive committee*: Dr. August Hoch, chairman; Dr. George Blumer, Miss Julia C. Lathrop, Dr. William Mabon, Dr. William L. Russell and Dr. Lewellys F. Barker. Gifts of \$44,500 by Mrs. Elizabeth Milbank Anderson and \$40,000 by Mrs. William K. Vanderbilt for the general work were announced, and the Rockefeller Foundation has agreed to contribute for a series of years the money necessary to retain the services of Dr. Thomas W. Salmon, who has been medical director of the national committee for three years.

DR. CHARLES D. WALCOTT, secretary of the Smithsonian Institution, has received a letter to the effect that the Stazione Zoologica at Naples is in a somewhat serious condition financially, owing to the withdrawal of German support. The Smithsonian Institution maintains a table at the station, which is all it can do under existing conditions. The writer of the letter suggests that if our universities would take up some of the vacated tables, it would not only assist the station, but would eventually result in closer cooperation between our scientific men and those of Europe.

AT the meeting of the Royal Geographical Society on January 11 the president made the following statement: "Before we come to the

business of the evening, I have a piece of news to tell you which I am sure you will be glad to hear. A very distinguished honor has been bestowed on our old friend and secretary, Dr. J. Scott Keltie. The American Geographical Society has conferred on him the Cullum gold medal, a medal which is given not annually but only on special occasions. I believe it has been given to only seven or eight people since it was founded, and amongst the holders have been Captain Scott, Dr. Nansen, Admiral Peary, and others of equal eminence. You will also be glad to hear that the council has made an arrangement by which, when Mr. Arthur Robert Hinks succeeds in March next to the posts of secretary and editor, Dr. Keltie will remain with us for another two years as joint editor of the *Journal*, and will thus be able to give his successor the help of his long experience when taking over these offices."

The Spingarn medal of the National Association for the Advancement of Colored People, which is to be awarded annually to the man or woman of African descent and American citizenship who shall have made the highest achievement during the preceding year in any field of elevated or honorable human endeavor, was given to Dr. E. E. Just, of the Harvard University Medical School, for his work in physiology and in improving the standard of negro medical schools. The medal was presented by Governor Whitman at a meeting held in New York City on February 12.

M. ROBERT JONCKHEERE, of the University of Lille, is now at the Royal Observatory, Greenwich.

P. S. BARNHART, late assistant professor of zoology at the University of Southern California, and a member of the U. S. Fish Commission forces at Venice, California, has recently joined the staff of the Scripps Institution for Biological Research of the University of California, where he will arrange an aquarium for the exhibition of live animals and continue the development of the institution's museum of Pacific Ocean animals.

MR. B. F. GROUT, consulting engineer of Pittsburgh, who at one time was a professor in the school of mines of the University of Minnesota, has recently been engaged by the Minneapolis General Electric Company, in connection with the tests of the efficiencies of its turbines in the Coon Rapids Plant.

MR. ARTHUR G. WEIGEL, a graduate assistant in chemistry at the Massachusetts Agricultural College, has accepted a position as chemist in the Experiment Station at Stillwater, Oklahoma.

DR. HENRY S. PRITCHETT, president of the Carnegie Foundation, delivered the dedicatory address at the dedication on February 20 of the new Municipal Hospital of the city of Cincinnati.

BEFORE the Geographic Society of Chicago on February 26, a lecture will be given by Dr. Homer L. Shantz, plant physiologist, U. S. Department of Agriculture, on "The Natural Vegetation and Agriculture of the Great Plains and the Great Basin."

DR. CHARLES H. T. TOWNSEND, of Washington, D. C., delivered the principal address at the Tenth Annual Banquet of the Tompkins County Medical Society, held at Ithaca, N. Y., on February 16, his subject being "Veruga and its Transmission."

SIR W. WATSON CHEYNE delivered the Hunterian oration at the Royal College of Surgeons on February 15, his subject being "The Treatment of Wounds in War."

IN an address before the Surgical Society of Paris on February 6, Dr. Truffier is reported by the *Medical and Surgical Journal* to have said that of the 14,000 surgeons in the French army, 6,500 are now at the front. Up to the close of December 93 surgeons had been killed, 200 wounded, 440 were missing.

WE learn from *Nature* that the monument on the grave of the late Dr. Alfred Russel Wallace in the cemetery at Broadstone, Dorset, is a fine specimen of fossil tree from Portland, seven feet in height and weighing some two tons. The specimen stands on a foundation of Purbeck stone, and an inscription on

it indicates merely Dr. Wallace's name and dates of birth and death.

As we have already noted a monument has been erected at Finse, among the mountains of southern Norway, in memory of Captain Scott and his companions. We learn from the *Geographical Journal* that at the unveiling of the monument on December 28 by Dr. Skatnum, vice-president of the Norwegian Geographical Society, made feeling reference to the noble characters and heroic deaths of the explorers. "Could anything," he asked, "be conceived more elevating from its grand ideality, than the conduct of Scott and his followers during their final death-march? It represented the very highest display of moral strength, the greatest possible exhibition of physical and mental fortitude and endurance." A second monument, subscribed for by Norwegian friends and admirers, and by British residents in Norway, will be erected at Fefor in Gudbrandsdalen, the place chosen by Scott for the trial of his motor sledges and other polar outfit. A memorial to Lieutenant Bowers, placed in Bombay Cathedral by his fellow-officers of the Royal Indian Marine, has also been lately unveiled, the ceremony being performed by Lord Willingdon, governor of Bombay. It is in the form of a simple tablet of marble, with an inscription quoting Captain Scott's tribute to Bowers as "cheerful, hopeful and indomitable to the end."

DR. JAMES J. SCANNELL, director of the bacteriological laboratory of the Boston Board of Health, died on February 19.

DR. ADAM MASSINGER, of the Heidelberg Observatory, has been killed in the war.

DR. O. K. SPRENGEL, surgeon-in-chief of the public hospital at Braunschweig and president of the German Surgical Association, has died from septic infection, professionally acquired, aged sixty-two years.

DR. WILLIAM J. MAYO and Dr. Charles H. Mayo, of Rochester, Minn., the distinguished surgeons, have decided to establish a \$1,000,000 foundation for medical research and to place the foundation, under certain restrictions, in the hands of the University of Minnesota

board of regents. It is planned that interest from the fund be used in research work at Rochester, open to graduate university medical students and leading to an additional degree granted by the university.

MIDDLEBURY COLLEGE has received for its botanical collection from Miss Annie Lorenz, of Hartford, Conn., a nearly complete set of the Hepatics of Vermont.

WE learn from the *British Medical Journal* that the statutory annual general meeting of the British Medical Association will be held this year, and also a meeting of the representative body, but at its meeting on January 27 the council decided that it would not be desirable, owing to the conditions brought about by the war, to hold the usual full annual meeting, with its scientific sections and social arrangements. A very large number of members of the association are directly occupied in work with the army in the field, or with the new armies that are being prepared, or in treating the wounded, while others not so engaged find the calls upon their time and energy, due to the withdrawal of so many medical men from ordinary practice, altogether unusual. Moreover, the annual meeting was to have been held this year in Cambridge, but the special circumstances of a university town deprived of many of its teachers and students by the war, and heavily committed to assist the Belgian universities, whose work has been suspended in their own country, make it impossible for Cambridge to maintain its invitation for this year.

THE *Journal of the American Medical Association* states that medical students from the University of Toronto will largely compose the staff of the Clearing Hospital which will accompany the Second Canadian Contingent to France. Between forty and fifty fifth-year medical students will be taken following a request for volunteers. They will be given credit for their year on enlisting. The organization of the unit is in charge of Dr. George S. Rennie, Hamilton, Ont. When it arrives in France it will be in charge of Dr. Wallace A. Scott, Toronto, who went with the first contingent. Accompanying it will be Dr. George

S. Strathy and Dr. L. Bruce Robertson, Toronto, and Drs. Foster and James E. Davey, Hamilton. Dr. H. B. Yates, Montreal, is to be second in command to Dean Herbert S. Birkett of the medical faculty of McGill University and of the McGill University General Hospital, which is to go to France. The other officers who are to be appointed to the various ranks are: Drs. John M. Elder, John McCrae, J. George Adami, W. Henry P. Hill, Edward W. Archibald, A. Howard Pirie, L. J. Rhea, William G. Turner, C. P. Howard, Herbert M. Little, William B. Howell, Colin K. Russel, John W. Hutchinson, John C. Meakins, William W. Francis, J. A. MacMillan, R. H. M. Malone, Laurie H. McKim, and Mr. David Law, all of Montreal.

THAT Baltimore is gambling with the health of the people and the commerce of the port against the probability of an epidemic of the bubonic plague and that preventive measures ought to be taken to prevent a development of the plague here was stated by Dr. William C. Rucker, Washington, D. C., of the U. S. Public Health Service, in an address before the Public Health Conference, recently held in Baltimore, which is quoted in the *Journal* of the American Medical Association. He made it plain that every municipality that failed to take preventive measures is likely to find itself in the position of New Orleans, where the government, state and city authorities were spending hundreds of thousands of dollars to wipe out the bubonic plague, which might have been prevented, had there been a rodent survey of the city. The federal government has been willing to cooperate with the city authorities of Baltimore in making a rodent survey, but the city has refused to appropriate any money for such a purpose, although Health Commissioner Gorter has asked for such an appropriation.

New exhibits in the department of vertebrate paleontology of the American Museum of Natural History have recently been opened to the public. The first of these is a skeleton of *Scelidotherium*, which is a part of the Cope Pampean collection secured through the

generosity of the late Morris K. Jesup, former president of the museum. This animal belongs to the sloth family and is interesting anatomically in its approach to the anteaters. Two nearly perfect skulls of horned dinosaurs have been added to the reptile collection. These are a part of the collection made by the museum expedition to the Red Deer River, Alberta, in 1913. The skeleton of the giant carnivorous dinosaur, *Tyrannosaurus*, is being mounted in the Pleistocene hall, and the new duck-billed dinosaur, *Corythosaurus*, in the dinosaur hall.

UNIVERSITY AND EDUCATIONAL NEWS

GIFTS of \$25,000 to Yale University were announced at a meeting of the Yale Corporation held on February 15. Mrs. Charles W. Goodyear and Anson Conger Goodyear, of Buffalo, N. Y., have given \$15,000 for the establishment of the Charles W. Goodyear fund in the Forestry School. The income of \$10,000 from John B. Thomas, of New York, is to be used for providing for lectures by men of distinction on "The Real Purpose of the College Course," and kindred topics. These lectures are planned primarily for the academic freshmen.

THE new science building at Goshen College which is in process of construction will be dedicated on May 27. The principal address will be delivered by Dr. Eugene Davenport, dean of the college of agriculture and director of experimental station of the University of Illinois. This event will also mark the formal opening of the new departments of agriculture and domestic science at Goshen College.

THE University of Oregon has just completed a new psychological laboratory for both practice and research work. It consists of a suite of nine rooms, in addition to the lecture room, all of which are equipped with power circuits, gas, compressed air and an intercommunicating system of wires and speaking tubes.

AT Yale University, Lorande Loss Woodruff, Ph.D. (Columbia), assistant professor in the Sheffield Scientific School, has been elected professor of biology in Yale College.

In the University of London, Dr. Edward Barclay-Smith, of Cambridge, succeeds Professor Waterston in the chair of anatomy at King's College, and Dr. E. P. Cathcart, of Glasgow, succeeds Professor Leonard Hill in the chair of physiology at London Hospital Medical College.

DISCUSSION AND CORRESPONDENCE

EFFECT OF CYANIDE OF POTASSIUM ON TREES

TO THE EDITOR OF SCIENCE: My attention has been attracted to an article in your columns by Professor H. A. Surface relative to the use of cyanide of potassium for eliminating insect attacks on trees. While I have not investigated the claim of the firm at Allentown, Pennsylvania, referred to in his article, and know nothing about their process, however, from my own results with cyanide of potassium, especially on elms and black locusts, I am convinced it is a valuable remedy.

The article above referred to gives the general impression that cyanide of potassium is the cause of tree death as well as various staining effects found in the bark, cambium, etc. My opinion is that the staining comes from the reaction between the tannic acid found in all trees and the iron found in this so-called "tree food" in the form of iron sulphate. It is well known that when solutions of tannic acid are brought into contact with iron or any iron salt, dark colored compounds resembling ink are formed. These are very permanent dyes and no doubt account for the dark color observed.

The cyanide of potassium as I have used it for years in eliminating borers from various trees has never caused any staining, nor have I ever known of its killing or in any way injuring a tree. I have been using it and prescribing it for the use of others for about twelve years in connection with my forestry work, and we have saved the lives of thousands of trees by means of it.

Large groves of thrifty elms and black locusts in Kansas and other parts of the west have been completely rescued from the attacks of boring and girdling insects by means of

cyanide of potassium, and this article is the first intimation I have ever had to the effect that it is deleterious to tree growth. I am strongly inclined to feel that the blame is not properly placed and that a highly useful chemical for insect eradication is being condemned because of damages produced by other substances.

C. H. SHATTUCK

GOSSYPOL—A TOXIC SUBSTANCE IN COTTONSEED.

A PRELIMINARY NOTE

We have separated from cottonseed kernels a substance which appears to be identical with the substance which Marchlewski¹ separated from crude cottonseed oil and called gossypol.

We have administered in various ways, to rabbits, gossypol as prepared by us and have found it toxic in every case.

We have found as did Marchlewski that gossypol is quickly oxidized in an alcoholic solution of sodium hydroxide.

In a previous paper from this station² it was stated that "alcoholic alkaline treatment, very greatly diminishes if it does not entirely remove the toxic properties of the (cottonseed) meal," and it was suggested that the beneficial effect "may be due to hydrolysis or to the formation of a sodium salt or to some other change not yet determined definitely."

We now offer as an explanation that gossypol is a toxic substance and that its oxidation by an alcoholic alkali renders it nontoxic and thus diminishes if it does not entirely remove the toxic properties of cottonseed meal.

SCIENTIFIC BOOKS

Bausteine zu einer Biologischen Weltanschauung. Von JAKOB, BARON VON URSCHÜLL. München, F. Bruckmann A.-G. 1915.

¹ *J. für Prakt. Chem.* (1899), 60, p. 80.

² Withers and Ray, *SCIENCE* (1912), 34, p. 81.

Von Uexküll sketches and advocates a vitalistic "Weltanschauung" in eighteen popularized essays, collected for convenience into four larger groups, the whole, sponsored by Felix Gross, and dedicated to Stewart Houston Chamberlain. "Die Neuen Probleme" is introductory; "Der Neue Standpunkt" includes discussions of the invisible in nature, the "Merkwelt," and the problem of the animal mind; "Das Neue Weltbild" reproduces the tropical aquarium in a series of splendid word-pictures, and contains two essays devoted to the nature of life and five to the construction of a biological "Weltbild"; and finally, under the heading "Spezielle Fragen" we find ideas on morphogenesis, Mendelism, the origin of space, and a discussion of Pawlow's work in which for the first time in the reviewer's experience trypsin is met with playing the rôle of the "Hauptsprengstoff für die schwer verdaulichen Fette" (p. 298).

Inasmuch as the arguments on which von Uexküll bases his vitalistic teachings have been discussed in an earlier review¹ and the present work contains nothing new in this respect, we may pass these over without further ado. There are three matters, however, which seem to deserve fuller mention; the first has to do with the general purposes of the book, the second, with the temperamental backgrounds of vitalism, whereas thirdly, we must consider a method proposed for application in the field of animal behavior.

To begin with, then, von Uexküll does not aim his guns primarily at the body of trained unbelievers, but, profiting by the experience of the Darwinian period of open debate, attempts to recapture for vitalism the public opinion taken in the earlier period by mechanistic assault. Such victories are theoretically quite beside the mark, but no one can look into the history of things without forming the impression that public opinion played an important part in the advance of mechanistic doctrine.

For the execution of this turning movement von Uexküll appears well equipped.

He is afire with enthusiasm, gifted with a pretty wit, and is master of a literary technic the like of which has not been seen in biological circles since the days of the great Darwinian apologists. Furthermore, temperamental qualifications of another sort do special service in the hands of our reformer, and this brings us to our second point.

As some men under the strains of life are driven to church, so others, impressed with the difficulties of biology, take to vitalism. The impelling embarrassments are partly objective and well known to all; others, however, are individual, and of these von Uexküll carries a heavy load. One who asserts, "Die Amöben bleiben zeitlebens ein strukturloses Protoplasmahäufchen" (p. 210) and who claims, "In ganz frühen Stadien . . . besitzt der Keim keine Struktur" (p. 270), must be constituted blind to some of the best things in modern research.

In addition to these and numerous other specific subjective results, our author also sees in the lay mind many dire effects of current teachings. The world instructed by mechanical philosophers has lost the joy of life—"der Sternenhimmel ist den meisten Menschen zu einer greulichen verworrenen Rechenmaschine geworden, die ihnen einfach ekelhaft ist" (p. 259); men spend their days in senseless enumeration; believe that all the invisibles in nature are gases; accept a chemical morality but not its mirrored image; and, by the gradual working inward of their algebraized symbolism, are ailing and dying at the heart.

How much of this tragedy is true to life and how much a romantic adventure, is in the light of recent events not so easy to determine. It is hard, however, to consider all this a necessary consequence of mechanism, since Berkeley implied long ago that thoroughgoing mechanism and idealism may dwell at peace in the same mind. We are disposed to regard such lignifications of the heart and intellect, supposing them for the moment to have some objective reality, not as the inevitable results of a mechanism free from exaggeration, pretension and carelessness, but rather as the products of temperamental reactions to

¹ "Umwelt und Innenwelt der Tiere," *SCIENCE*, N. S., Vol. XXXI, pp. 303-305.

mechanism such as it unfortunately often is. All of which is suggestive not only to those who wonder why Germany, of all places, should prove a relatively favorable soil for modern metaphysics, but to those also who ask whether the vitalistic-mechanistic debate can be closed.

Quite apart from these matters, von Uexküll's treatment of the environment, and of the relations of the organism thereto, has distinctly practical interest for the experimentalist. For Driesch the environment does not exist. Neither index of the two volumes on the "Science and Philosophy of the Organism" contains the word, nor is any discussion of the abode of life to be met with anywhere in the seven hundred pages of dreary text. Von Uexküll, on the contrary, is all aglow for the environment and its significance in the interpretation of life. Nor have these differences been without importance for the two authors under comparison; Driesch's reorganization of things biological has driven him out of the very field which should have proved more interesting than ever before; von Uexküll is continuing concrete observations and experiment and is pointing the way to further investigation with commendable fervor.

According to our writer, the environment of a living thing acquires special biological significance for us only when we discover and analyze those elements that actually act upon and with the organism in the normal give and take of daily existence. Such elements constitute the "Wirkungswelt." Further analysis differentiates out of the "Wirkungswelt" a "Merkwelt" which in the case of human beings, and perhaps wherever else it occurs, is specific for each individual.

These terms are practically self-explanatory. Air, for instance, is distinctly in our "Wirkungswelt," but may enter the "Merkwelt" under special circumstances. Now von Uexküll takes the position that students of behavior should limit themselves to a discovery by experiment of markworlds, and leave psychological considerations alone; brains and the objects of the external world can be experimented with, but of psychoses we can

know one set only. The much exploited wonder-horses of Germany, the trained apes that open bolted doors, ring bells and order dinner, are monstrosities that have been forced to respond to the human order and not to normal constituents of either the horse- or monkey-world. Whether they have come to make these responses by trial and error, imitation or a system of rewards and punishments, is interesting only as a contribution to the art of unnatural history.

How the psychological difficulty is to be outflanked by this maneuver is not clear. The scallop's eye forms a retinal image like our own, yet the scallop "sees" only movements. To the specific forms, colors, sizes and the thousand other traits by which we distinguish one moving object from another this animal is blind. For the scallop a starfish, for us without taste or smell, has a pronounced odor indistinguishable from other chemical effects. Three marks in the following definite order (*time-scheme* as opposed to *space-scheme*) constitute a starfish in the scallop's "Merkwelt": movement, a general chemical mark, and a tactile stimulus. Given these in their orderly connection and the starfish is—"wargenommen"—that is, *perceived, observed, felt, taken care of, attended to, or availed of*, by the scallop. Clearly, until von Uexküll furnishes us with a system of notation by which the results of his experiments can be described without using words that suggest to every one the very thing upon which he has turned his back, discoveries concerning the markworld of the scallop are not likely to free us from the difficulties of an unanswerable question.

This does not mean that the method is inapplicable to cases in which the psychological question is respectable. On the contrary, James, in his essay "On a Certain Blindness in Human Beings," placed emphasis on the same spot fifteen years ago. In comparative psychology, and especially in experimental studies on human behavior, on the practice of education, and on the art of right living, numerous applications suggest themselves. If students adequately trained in the methods of science will seriously take up the experimental

analysis of normal markworlds, we may expect significant results in a field which needs them perhaps more than any other among the biological substations.

SPECIAL ARTICLES

THE IDENTITY OF HELIOTROPISM IN ANIMALS AND PLANTS. SECOND NOTE¹

PAUL BERT had shown in 1869 that if the small fresh-water crustacean *Daphnia* is exposed to a solar spectrum it goes towards the source of light in all parts of the visible spectrum, but most rapidly in the yellow or green.

*Il fut facile de remarquer qu'elles accouraient beaucoup plus rapidement au jaune ou au vert qu'à toute autre couleur.*²

The fact of the predominance of the heliotropic efficiency of the yellowish-green in these and some other animals led the ophthalmologist Hess to two assumptions, first that they are totally color-blind (since the yellowish-green part of the spectrum is the brightest for the eye of the totally color-blind human) and second, that the sensation of brightness is the cause of the heliotropic reaction of animals. It is obvious that these conclusions go beyond the facts, since we have no proof for the assumption that the heliotropic effects of light in lower animals are accompanied or deter-

mined by any sensations of brightness and since totally color-blind humans do not show any positive heliotropism. In consequence of his two arbitrary assumptions, Hess is forced to the further conclusion that the heliotropic reactions in animals and plants can not be identical, since he does not seem ready to discuss the light and color sensations of plants, and he tries to support this conclusion by the statement that heliotropic plants and animals are sensitive to different parts of the spectrum, all animals to the yellowish-green, all plants to the blue. We have already pointed out in our previous note³ that this latter statement is not correct, since we were able to show that for the positively heliotropic animal, *Eudendrium*, the most efficient part of the spectrum lies in a carbon arc spectrum in the blue near the region $\lambda = 474 \mu\mu$, where it also lies, according to Blaauw, for the seedlings of oats.

It seemed of interest to find out whether for different motile unicellular organisms which contain chlorophyll and which are on the border line between plants and animals the most efficient part of the spectrum for the production of heliotropic reaction lies always in the same region. We investigated the reactions of *Chlamydomonas pisiiformis* and of *Euglena viridis* in a carbon arc spectrum. The investigation of the behavior of these organisms in the spectrum showed a marked difference. *Euglena* gather in the blue part of the spectrum, usually in the region between $\lambda = 438$ and $\lambda = 510 \mu\mu$. The densest gathering was generally in the region of $\lambda = 475 \mu\mu$. In the case of *Chlamydomonas* the gathering always went much farther towards the yellow, usually having its limit in the region of about $\lambda = 560$ or $\lambda = 570 \mu\mu$. It was in most cases not easy, however, to ascertain the region of maximal gathering, though in many cases it seemed to be about $\lambda = 520 \mu\mu$. The most remarkable difference between the behavior of the two forms in the spectrum was therefore the fact that *Chlamydomonas* was sensitive to longer waves than *Euglena*.

It soon became obvious that this method of procedure does not permit the decision of the

¹Loeb and Wasteneys, *Proc. Nat. Acad. Sc., I*, p. 44, 1915.

²Paul Bert, *Arch. de Physiol.*, II, p. 547, 1869.

³Loeb and Wasteneys, *Proc. Nat. Acad. Sc., I*, p. 44, 1915.

question of the relative efficiency of the different parts of the spectrum for both forms with sufficient accuracy. We selected, therefore, a different method which allowed us to compare the relative efficiency of two narrow parts of the spectrum. A carbon arc spectrum, 23 cm. wide, was thrown on a black screen *SS* (see

FIG. 1.

Fig. 1) with two slits *a* and *b* in the two different parts of the spectrum which were to be compared in regard to their heliotropic efficiency. The two beams of light passing through the slits are reflected by the two mirrors *M* and *M*₁ into the square glass trough in such a way as to strike the same region *g* of the back wall of the trough. The glass trough is surrounded by black paper except at *R* and *R*₁, where the two beams of light enter from the mirrors. Before the experiment begins, all the organisms are collected in the region *g* by a special arrangement which need not be described here. As soon as the spectrum is turned on, these organisms are simultaneously exposed to two different beams of light which come from the two mirrors *M* and *M*₁. When one type of light, *e. g.*, that from *M*₁, is much more efficient than the other coming from *M*, practically all the organisms are oriented by the light from *M* and move toward

this mirror, collecting in the region *R*. When the relative efficiency of the two types of light is almost equal the organisms move in almost equal numbers to *R* and *R*₁. By using as a standard of comparison the same region of the spectrum and successively altering the position of the other slit in the spectrum we were able to ascertain with accuracy the relative efficiency of the different parts of the spectrum for the two forms of organisms. When the two parts of the spectrum which are to be compared are very close to each other it is necessary to deflect the beams with the aid of deflecting prisms, before they reach the two mirrors. It turned out in these experiments that for *Euglena* the region of maximum efficiency was in the blue between $\lambda=462$ and $\lambda=492 \mu\mu$; while for *Chlamydomonas* it was in the green or greenish-yellow between $\lambda=529$ and $\lambda=539 \mu\mu$. In other words, *Euglena* behaved like the seedlings of oats and like *Eudendrium*, both of which had their maximum of efficiency in the blue (in the carbon arc spectrum); while *Chlamydomonas* behaved like *Daphnia*. We may remark incidentally that earlier experiments by Loeb and Maxwell¹ on *Chlamydomonas* had led these authors to the same conclusion.

From the viewpoint of Hess, which seems to have met the approval of several German physiologists, we should be forced to conclude that the unicellular green organism, *Chlamydomonas*, has sensations of brightness, that it is totally color-blind and that it is not heliotropic; while the unicellular green organism, *Euglena*, has no sensations of brightness, is not color-blind and is heliotropic. The confusion created by this mode of reasoning is increased if we consider that *Chlamydomonas* is usually claimed by the botanist and *Euglena* by the zoologist.

We are inclined to put a different interpretation upon our observations, namely, that heliotropic reactions may be determined by two different types of photosensitive substances or by the same type of photosensitive substance in two modifications. One of these types of substances or modifications has its maximum

¹ Univ. Calif. Publ. Physiology, III., p. 195, 1910.

of sensitiveness in the blue (in the neighborhood of $\lambda=477\mu$), the other in the yellowish-green (in the region of $\lambda=534\mu$). The latter type is found in *Chlamydomonas*, *Daphnia*, the larvae of barnacles and other organisms; the former type exists in *Euglena*, *Eudendrium*, the seedlings of oats and others.

It seems of interest to call attention to the fact that according to the measurements of Trendelenburg the visual purple in the eye of the rabbit is bleached most rapidly by light of the wave-length $\lambda=536\mu$. As Kuehne had already shown, visual purple is not affected by red light, and only feebly by yellow light. The relative efficiency of different parts of the spectrum for the heliotropic reactions of *Chlamydomonas* coincides, therefore, approximately with the relative bleaching power of rays of different wave-lengths for visual purple. This makes it almost appear as if in the one group of organisms, namely, those which behave like *Daphnia* or *Chlamydomonas*, the heliotropic reactions were determined by a substance or by substances which behave in regard to photosensitiveness like visual purple; and which may possibly be identical with visual purple.

This assumption allows us to explain the heliotropic reactions of lower organisms without arbitrarily ascribing to them sensations of brightness the existence of which can in their case not be proved. And, furthermore, when the heliotropic effect of rays of different wave-lengths upon lower organisms is found to run parallel to their effect upon the bleaching of visual purple (as it does in *Daphnia* and *Chlamydomonas*) it seems more rational and promising to conclude that the heliotropism in these cases is caused by a substance or substances which behave photochemically like visual purple than that these lower organisms suffer from total color-blindness. We have already shown in our first note that the theory of heliotropic orientation is independent of the relative efficiency of different wave-lengths.

We may summarize the results of our experiments in the following way:

1. The validity of the Bunsen-Roscoe law for the heliotropic reactions of certain (and possibly all) plants and animals suggests that

these reactions are due to a chemical action of the light.

2. There seem to exist two types of heliotropic substances, one with a maximum of sensitiveness (or absorption) in the yellowish-green (near $\lambda=534\mu$) and the second with a maximum of sensitiveness in the blue (near $\lambda=477\mu$). Visual purple is a representative of the former type.

3. The photosensitive substance of the visual purple type occurs in the protozoan *Chlamydomonas*, which is usually stated to be a plant, in *Daphnia* and many other organisms. The photosensitive substance with the maximal sensitiveness in the blue is found in *Euglena*, in many plants and in certain animals, e. g., *Eudendrium* and probably others.*

4. It would, therefore, be wrong to state that the one type of photosensitive substances is found exclusively in plants and the other exclusively in animals. As a matter of fact they are distributed independently of the systematic boundaries between the two groups of organisms.

5. It is immaterial for the theory of heliotropism to which of the two types the photosensitive substance in any given heliotropic organism belongs.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

SECTION M, AGRICULTURE

THE first meeting of Section M, Agriculture, of the American Association for the Advancement of Science, was held in the Engineering Building of the University of Pennsylvania, Philadelphia, December 30, 1914.

The inauguration of the new section was particularly auspicious, and the large attendance was encouraging as indicating wide interest. Dr. Charles W. Eliot, president of the Association, presided at the opening of the meeting, and in a brief address called attention to the great importance of the agricultural industry, and expressed

* This seems to be indicated by the work of Parker and his pupils.

his gratification at the provision of the section. It is high time, he said, that we began to attend to the building up of American agriculture, and to recognize its basis in science. He expressed his special interest in the teaching of agriculture on account of the opportunity it offered for furthering the teaching of natural sciences in the schools. This, he declared, is the great reform needed in American education. The popular interest now aroused in agricultural teaching offers an entering wedge in this direction, and gives hope for the accomplishment of even greater reforms. Country-life development Dr. Eliot pronounced "one of the greatest humanitarian movements of this age." Our race can not endure urban life and the factory system, he said; the ill effects of it have already been seen. "Hence anything that leads men into the country where they may lead a wholesome existence is contributing to a necessarily humanitarian movement."

These remarks furnished an appropriate introduction to the vice-presidential address of Professor L. H. Bailey, on "The Place of Research and of Publicity in the Forthcoming Country Life Development." The address was essentially a plea for the principles of democracy, approached from the standpoint of the public service institutions for agriculture, and especially the new national work for agricultural extension.

The other feature of the meeting was a symposium devoted to "The Field of Rural Economics." This was participated in by four speakers, who dealt with several phases of the general subject. In opening the subject, Hon. Carl Vrooman, Assistant Secretary of Agriculture, discussed "Rural Economics from the Standpoint of the Farmer." He corrected some of the false impressions as to the advantages of high acre yields, pointing out that the plain business question is not how much the farmer could produce if he had no regard for the cost, but how much he can afford to produce under present American conditions. He showed by statistics that the largest crops do not necessarily mean the largest net income to the farmer, and that in years of relatively small production he often realizes quite as much from his crops as in years of maximum yield.

Secretary Vrooman laid much emphasis on the importance of the problems of distribution and marketing, enforcing his remarks by illustrations from his own experience as a farmer. While admitting the necessity for middlemen and other intermediaries, he protested against any allied in-

terest taking more than a legitimate profit from the farmer. He declared that the average farmer is only making wages; he is not making a profit over his wages and the interest on his investment. Until the problems of agricultural economics are solved there is little encouragement for him in attempting to raise larger crops. "Economic justice to the farmer and producing classes," he said, "must be the basis of the higher civilization which we picture."

In discussing "Credit and Agriculture," Professor G. N. Lauman, of Cornell University, maintained that in this country credit has not been generally available to the farmer except at a considerable premium, and that in order to develop American agriculture and rural life it must be made feasible for a man to be successively a farm laborer, a farm renter and a farm owner. Short-time credit was held to be a distinctly local matter. The community should rally all its capital to develop itself, and should organize to furnish the basis for a closer association between itself and existing banking and credit facilities. The great social and ethical gains from the small credit unions of Europe was explained, especially in helping the small farmer.

In order to bring outside capital into agriculture it is necessary to meet the demands which such capital makes. Credit, it was declared, "has no better basis than farm values made fluid." Rightly developed, bonds based on land mortgages have no superiors in the investment field. These, it was explained, should be of small enough denominations to be accessible to all classes and available on all exchanges. But the prevalent machinery for this is too expensive a burden on agriculture.

Professor Lauman did not advocate leaving the problem to either the government or to private capital for solution, but urged organization. "If agriculture organized to make it possible to demand the lowest rates of interest the market affords, can not live and develop, not even state aid will prevent its ultimate decay."

In a paper on "Marketing and Distribution Problems," Mr. C. J. Brand, of the Department of Agriculture, presented the needs of the farmer in the way of assistance in establishing a market system which will return to him the true value of the various crops he produces, minus reasonable charges for handling, transportation and the legitimate profits of middlemen. He outlined the various lines of study which are being pursued by the Office of Markets and Rural Organization. These are concerned, in part, with a study of conditions

as they actually exist over the country in the handling and marketing of cotton, grain, live stock, meat and meat products, fruits, vegetables, dairy and other products, followed through from the producer to the consumer, with statistical studies of supply and demand. Market grades and standards are also being investigated, with the object of effecting greater uniformity; and transportation and storage, as to methods, the adequacy of facilities, and the relation of warehousing, refrigeration, etc., to prices and to stabilizing supplies.

Market surveys are being made with a view to collecting facts and developing methods for bringing useful information in regard to prices and supplies promptly to producers and consumers. The practise in vogue in marketing and distribution in large cities is the subject of a special inquiry, to make comparisons and arrive at the most advantageous plans. Direct dealing through marketing by parcel post and by express is being studied, not only as to practicability and advantages, but as to systems for bringing producers and consumers into contact and establishing their business relationships. Cooperative buying and selling naturally attracts considerable attention, with inquiry into the methods and success of organizations, and the supplying of assistance in organization, systems of accounting, auditing, etc.

The partial enumeration of these lines of effort illustrated some of the problems in marketing. From a consideration of cotton handling and marketing, Mr. Brand showed that the acute problems are not confined to perishable crops. The cantaloupe trade was cited to show an overdevelopment of the industry, due to ignorance as to the development of competitive areas, which in 1914 resulted in disaster to the producers and to the large distributors. As usual, the slump in prices was not reflected in the retail trade, consumers paying practically as much as in a year of scarcity, while the surplus went to the dump. The conclusion is that "until we have a more complete system of information and a better adjustment of production to market requirements, this problem will continue to be with us."

Cooperation was not regarded as necessarily the panacea for all marketing troubles. Organization was favored, but alone it is not sufficient; it must be accompanied by skillful and intelligent management. To protect shippers from imposition and misrepresentation at large markets and terminals, a licensed inspection system was suggested, and illustrations of the use it could serve were cited.

"The Distinction Between Efficiency in Produc-

tion and Efficiency in Bargaining" was well illustrated by Dr. T. N. Carver, of Harvard University. He explained that every legitimate business is made up of two parts, one of which may be called producing, including any handling of the material which renders it more usable or useful, and the other bargaining, i. e., buying and selling, borrowing and lending. Many of the supposed economies of large-scale business turn out upon examination to be advantages in bargaining rather than economies in production. In most lines of business there is a certain size which gives the maximum efficiency in production, and also in bargaining. These do not necessarily coincide, but as a rule, the size which gives the maximum efficiency in bargaining is larger than that for production.

In agriculture the most efficient producing unit was said to be the one-family farm, provided with the best teams, tools and general equipment. This gives the highest average product, man for man. If the large farmer is able to command some special advantages in securing cheap labor, he may beat the small farmer in competition with him, but this is advantage in bargaining. His profit may be larger, in spite of the lower average productivity of the persons engaged. The foisting upon the rural districts of a large supply of cheap labor is designed to give the large farmer an advantage in purchasing his labor.

Again, it was pointed out that in buying his supplies and in selling his products, especially if they are perishable, the large farmer usually has an advantage. "The small farmer of the present day is the only large class which regularly buys its raw material at retail and sells its finished product at wholesale." This can be overcome by "collective bargaining" or cooperation, which may give the small farmer the same advantages which the large farmer enjoys; and the same is true in borrowing capital. Hence for the small farmer, who appears to be efficient in production, organization into larger units was urged, to overcome inefficiency in buying and selling.

Dean E. Davenport, of the University of Illinois, was elected vice-president and chairman of the section for the ensuing year, Dr. A. C. True, of the Office of Experiment Stations, was chosen member of the General Committee of the Association; Dr. W. A. Taylor, of the Bureau of Plant Industry, member of the council, and President Kenyon L. Butterfield, of Massachusetts, a member of the sectional committee (for five years).

THE VALUE OF ZOOLOGY TO HUMANITY: THE CULTURAL VALUE OF ZOOLOGY

ALL sciences are so interrelated that it is not easy to point out the distinctive contributions of any one science to human welfare, and in particular I have found it impossible to separate zoology from other biological sciences in this regard. Accordingly, in what I shall say it will be understood that I am speaking for all the biological sciences and not for zoology alone.

Again culture is no single definite object, but a general and rather indefinite ideal. There are many kinds of culture—physical, intellectual, moral, esthetic, religious, governmental, etc.—but each and all forms of culture may be regarded from the standpoint of the individual or from that of society; the former we call education, the latter civilization.

I. CONTRIBUTIONS OF BIOLOGY TO EDUCATION

The method of the scientist is to generalize only from particular objects or phenomena, and a naturalist, if asked what the cultural value of biology is, would ask to see some of the specimens. The members of this society are my specimens, my living exhibits of the cultural value of biology. What are your distinctive cultural characteristics? To avoid the personal error it would have been well to have asked each one of you to describe the characteristics of some other member of the society, but making allowance for the personal error, I believe that the biologist shows the following qualities:

1. Immense enthusiasm and intense con-

¹ Four papers in a symposium before the American Society of Naturalists, Philadelphia, December 31, 1914.

MS. Intended for publication and books, etc., intended for review should be sent to Professor J. McKean Cattell, Garrison-Hudson, N. Y.

centration in his work. He desires no vacations except for bug-hunting and collecting. His idea of a good time is to have a day off for work with his microscope. He is a biologist because the tendency within him is too strong to be resisted. He feels that he was born for one work only. In a peculiar sense he has had the baptism of science—he has “renounced the Devil and all his works, the vain pomp and glory of the world,” and has devoted himself with singleness of purpose to one particular subject which seems to him the central theme from which all others radiate.

But this very enthusiasm and concentration has its dangers for it is liable to destroy the sense of perspective and proportion. President Lowell has several times referred to a university course, whether real or mythological he does not say, on the “Antennæ of the Paleozoic Cockroach”—a highly specialized course, it must be admitted, and yet probably no more so than many others to be found in our universities. Our opinions regarding the value of any subject are greatly influenced by our knowledge or ignorance of that subject. There are persons who laugh at all foreigners; they think “they are so funny.” There can be no doubt that specialization on any subject which is out of the ordinary seems funny to those who think only conventional thoughts. A great biologist was once at a public reception where he looked and doubtless felt much out of place. A society woman tried to engage him in small talk, but he replied, “Madam, the Maryland oyster is being exterminated.” The original “Professor Mooner” of the comic papers was probably an old-fashioned naturalist. Intense devotion to work is a fine thing and has cultural value if properly balanced by a true sense of proportion, but the effect is otherwise if this concentration blots out for one the rest of the universe.

The evil effects of over-specialization are shown in many ways among biologists—not only in the lack of ability to understand or appreciate many other lines of work, but also by the very prevalent notion that the biologist who engages in economic work or who devotes himself to public service has somehow lost caste, and also by the contrasting opinion held by some “practical” biologists that “academic biology should be classed with embroidery.” There are many good biologists in economic work, but there are relatively few in public life, and it is a pity that it is so, for on many biological problems of the highest interest to society the biologist could speak with an authority at least as great as that of the sociologists, who are frequently more sure of our results than we are ourselves, an authority greater than that of the propagandists who invent their own biology. On the other hand, there are a few great leaders in biology who have become teachers and interpreters to the plain people, men who like Huxley, Galton, Metchnikoff and Forel have dared to apply the teachings of biology to social problems, and there are more biologists who would do this if they were not restrained by the fear of losing caste among extreme specialists.

But, after all, concentration and narrowness are by no means characteristic of biologists and are probably to be ascribed to the weakness of human nature rather than to the influences of biology.

2. A second quality which is more truly distinctive of the biologist is to be found in his powers of observation and imagination. Other sciences also train both of these faculties, but in a peculiar sense the living world is an eternal challenge and stimulus to the powers of observation and constructive imagination.

No one can have failed to notice the great interest which all persons show in living objects. Men, women and children will

watch without weariness the movements of living things when they could not be induced to study the pictures of them in a book. Even many of the higher animals show great interest in and curiosity about moving objects which would remain unnoticed if perfectly still. Is not the source of this universal interest in living things to be found in the fact that we recognize in them fellow creatures with feelings akin to our own? Is not the great craze for moving pictures due to the fact that the movements make the pictures live?

Instinctively we recognize the kinship of all living things; instinctively we attribute to them the joy and sorrow, the fear and courage, the love and hate which we also experience; instinctively our curiosity is aroused and our observation and imagination are stimulated. And when we are older grown and have learned more about the "mechanism of life" do we not find that our curiosity, admiration and wonder are increased rather than diminished? Does not the great mystery of life appeal to the biologist even more than to others? I am sure that I represent the experience of every biologist when I say that the living world is a powerful and unailing stimulus to the faculties of observation and imagination.

3. Biology occupies a unique place among all the sciences in its cultivation of æsthetic appreciation and broad sympathies. It was for this reason that the late Professor Blackie said that he would have all young persons taught music and natural history. The naturalist is an artist in spirit if not in technique. It is sometimes a question how to classify the great artist-naturalists of the past such as Leonardo, Chamisso, Goethe and Audubon, and even if in these days of greater specialization the technique of art and of science are rarely combined in the same person the

spirit of the two is combined in every naturalist worthy of the name and not infrequently strives to express itself in the figures and plates with which he adorns his scientific papers.

The biologist is thrilled by the beauty, the fitness, the mystery of organisms, and no scientific explanations of this beauty, fitness and mystery can destroy the æsthetic appreciation which they cultivate. In the anatomical study of dead bodies there is less of this æsthetic sense than in the study of living, moving, sentient beings, and yet was it not Johannes Müller who said "The anatomist should have the eye of an angel, the hand of an artist and the stomach of a pig"?

With this æsthetic appreciation of nature there is mixed a broad sympathy with all living things. We can appreciate the feelings of that student who said that before he studied biology he used to try to crush the earthworms on the walks, but now that he had learned something about their marvellous structures and habits he carefully avoided stepping on them. Every ornithologist can appreciate the feeling of St. Francis of Assisi who called the birds his brothers. In this building which is a monument to his ability and energy I can not forget the naturalist Montgomery, who remembered to his dying day "the thrill with which he first heard the song of the blue bird" and who rejoiced that he was a part of immortal nature.

The biologist has his eyes open to the beauties, the joys, the sufferings of living things. What an outrage it is that he is so often pictured as a cruel and bloody monster! His sympathies extend not merely to his humbler brothers, but his human sympathies are broadened and deepened. The real naturalist can not look upon the Germans or Russians or French or English as monsters. He recognizes his kinship not

merely in body, but also in spirit to all of them, and he is able to understand and appreciate and in a measure to sympathize with all men. Hate and distrust are born of ignorance; knowledge brings sympathy. "To know all is to pardon all." Only a broader knowledge of and sympathy with our fellow men can end class and race antagonisms and guarantee a lasting peace. The study of biology, in broadening the sympathies of men and in cultivating esthetic appreciation, occupies a unique place among all the sciences.

These elements of personal culture are not absolutely distinctive of the biologist. Some persons wander into biology whose inherited tendencies are too strong to be overcome by its discipline; some good men in other fields are biologists gone astray; but in general these qualities are characteristic of the biologist.

II. CONTRIBUTIONS OF BIOLOGY TO CIVILIZATION

1. First among all the contributions of science to civilization stands the emancipation of man from various forms of bondage. Science has to a large extent freed civilized man from slavery to environment; it has well-nigh annihilated time and space, it has levied tribute upon practically the whole earth to supply his wants, it has taught him how to utilize the great resources of nature and to a large extent it has given into his hands the control of his destiny on this planet.

In this conquest of nature all sciences have been represented and it is difficult to apportion exactly the credit due to each. This is well illustrated by the various claims which are being made at present as to who built the Panama Canal. It is claimed by Colonel Roosevelt, by the army and navy, by the engineers, by the doctors and sanitarians, and one ought not to forget the workmen from the United States and the

Jamaica negroes, though they are saying little about it. That biologists can put in a strong claim can not be doubted when we reflect upon the former French attempt to build the canal and the ravages of malaria and yellow fever which helped to defeat that enterprise. I suggest as a topic for a general debate at the meetings of the American Association for the Advancement of Science at the Panama-Pacific Exposition next summer this question, "Who built the Panama Canal?" I am sure that biology will be able to show that it is entitled to a large share of the credit.

The contributions of biology to civilization are not generally regarded as equal to those of physics, chemistry or engineering, and yet they are many and great and are constantly increasing in importance. Indeed, the debt of civilization to biology is absolutely incalculable, as may be appreciated when one mentions merely the names of some of the biological sciences, as for example, agriculture, animal breeding, bacteriology, experimental medicine, pathology, parasitology, physiology, sanitation. All of the great advances in these fields in recent years are the results of the study of living things, whether that study was done in a biological laboratory or not, and they are therefore the contributions of biology to culture. Indeed, the very continuance of civilization depends upon biology; there were civilizations of the past which went down under the onslaughts of pestilence and famine, as well as of war, and if our civilization is to advance it must rely upon biology to teach improved methods of warding off disease, of increasing and conserving the food supply and of improving the human breed.

2. But the highest service of science to culture has been in the emancipation of the mind, in freeing men from the bondage of superstition and ignorance, in helping man

to know himself. The message of science to mankind has ever been the message of intellectual enlightenment and liberty, "Ye shall know the truth and the truth shall make you free."

The greatest contribution of biology to intellectual emancipation has been the doctrine of evolution, that great theory which has revolutionized all our thinking regarding man and nature. And evolution is the distinctive contribution of biology to civilization, for it was in the living world and especially in the human realm that the doctrine of evolution came as the great emancipator from superstition and ignorance. The greatest theme of evolution is not the origin of species, nor even the origin of living things, but rather the oneness of all life. This is indeed the greatest principle of biology, namely, that through all the endless diversity of the living world there runs this fundamental similarity and unity. We also are living things and all that concerns other forms of life is of direct interest to us. In the lower organisms we see ourselves in simpler and more primitive form; we see man from the standpoint of the whole living world, as superior beings in another planet might look upon us, and as a result we have ceased to a large extent to regard the universe as existing merely for us. In this intellectual revolution we have ceased to occupy a position of solitary grandeur in a little human universe; we have not grown less, but nature has become so much greater that man's relative position in nature has changed.

Contrast the old view of creation, that the universe was made in six literal days, with the revelations of science as to the immensity and eternity of natural processes. Contrast the old view that all organisms arose suddenly by divine fiat with the view that animals and plants and the world itself are the result of an immensely long

process of evolution. Contrast the old anthropocentric view of nature and of man with the new biocentric view which evolution has revealed; the old notion that man was absolutely distinct from all other creatures with the new conception of the oneness of life. As Darwin so beautifully says,

There is grandeur in this view of life with its several powers having been breathed by the Creator into a few forms or into one, and that whilst this planet has gone cycling on according to the first law of gravity from so simple a beginning endless forms most beautiful and most wonderful have been and are being evolved.

Biology has changed our whole point of view as to nature and man and has thus contributed more than any other science to the intellectual emancipation of mankind.

EDWIN G. CONKLIN

PRINCETON UNIVERSITY

THE VALUE OF SCIENTIFIC GENEALOGY

FROM out of the middle ages when learning was treasured by encloistered scholastics has come the tradition that science is necessarily esoteric; and that pure science has little or nothing to do with human affairs; and thus is to be contrasted sharply with the humanities. During the past half century anthropology, social as well as physical psychology and psychiatry, and medicine have developed into well-recognized sciences proceeding by methods as objective and experimental as physics or chemistry and contributing to our knowledge of the field lying between the sciences of biology and chemistry; and of behavior and morphology. To-day the man of science is quite willing not only to apply to the human species the laws that have been determined by the study of other organisms, but he is recognizing that man himself is as good material to use in getting at scientific principles as any other species; and that in certain subjects man affords the best mate-

rial for scientific investigation, and that the investigation of man gives a peculiar zest to research because the results are so obviously applicable to our human life. No doubt these considerations are responsible for the fact that to-day we are enquiring into the value of scientific genealogy.

Although the copy-book states that man is an animal, it appears that, until recently, zoologists considered that man is an anthropos and they had nothing to do with him. And so long as the work of the biologist was the description of species, or the study of structure this attitude had a certain justification. But a new era has arisen; an era in which for certain studies the old classifications of botany, zoology and anthropology are being disregarded. These studies may be grouped under the head of general biology. This field includes such matters as general cytology (embracing maturation and fertilization), general embryology (including physiology and chemistry of development), genetics, and general physiology (including irritability). And we find that the phenomena of these sciences are the same for *all organisms* and that all may be used to contribute data to these sciences. And now any biologist feels at liberty to use any material, from any "kingdom," for his studies.

Not only in this matter, but in another, a great change has entered the spirit of our dreams. Formerly the zoologist, still cherishing in manhood the childish delight of collecting animals and studying with uninhibited enthusiasm the details of their structure, found it difficult to answer the question that his fellow human beings put to him, "What are your studies good for?" was able to show few points of contact between zoology and human affairs (except the fisheries and some parasites) and so assumed the lofty attitude of esotericism. But now the biologist is dealing with facts

whose bearings are appreciated by any fairly well educated layman. Workers in any one of the fields of general biology are apt to be *importuned* by publishers; and there are men, though few in number, who live in luxury by writing books and giving popular lectures on biological topics! We have hardly to urge the importance of biology to humanity.

In no field of biology is there a greater popular recognition of the importance of biological research than in that of genetics. The reality and the bearing of the new science have gained a general recognition; the realization of the limitations of the methods of amelioration and of training and of hygiene have paved the way for such recognition; and to-day people are coming to look at man as the biologist does, namely, as an animal, comprising hundreds of elementary species, whose potentialities for physical, intellectual and moral development differ tremendously.

If there were anywhere a community that was wholly isolated, whose progenitors were exactly or very closely alike and which was highly inbred, then all the members of that hypothetical community would belong to the same species and it would follow that the facts of genetics would have little importance for such a community, and there would be little need in such a community for a scientific genealogy. But, as a matter of fact, the human race is practising what is, perhaps, the biggest experiment in hybridization that the world has ever seen. And this vast experiment is pregnant with possibilities for good or evil so great that they can not be calculated. Any practical breeder who was carrying on such an enormous system of cross breeding and attempted to keep the details in his head would be recognized as guilty of a colossal folly; and no scientific breeder would, of course, be capable of such

a thing. And yet this precious human kind of ours, whose progress is so fateful to the world, goes its blind way, like any jelly-fish, mates almost at random and then, after two or three generations, has lost all knowledge of the matings that have gone before. Of course, the race has got along, somehow, just as the lower animals get along; although we have been burdened with an intelligence sufficient to lead us to interfere with the operation of pure instinct but not sufficient always to interfere wisely. There are those who urge that the matter of marriage selection should be left to instinct; forgetting that in adult man (with his enormous development of the inhibitions) instinct has been so repressed as to have become a very unsafe guide. There are those who adhere to the obviously false doctrine that men are born equal and therefore it really doesn't matter who marries whom. It is, however, easy to show that it does matter tremendously. Also I think it quite within the range of possibilities that it will become incorporated into the mores that persons who are thinking of marrying should learn something about the genealogical history of the proposed parents of their children. And, again, it is highly probable that, after we have learned the method of inheritance of racial traits and can state the consequences (certain or probable) of particular matings, that such precise knowledge will influence human conduct even as a knowledge of the causes of yellow fever has influenced human conduct and has led to a vast reduction in the morbidity from that disease. When our knowledge of the inheritance of racial characteristics becomes fairly complete and widely diffused it can not be doubted that such knowledge will influence many selections of mates.

The fact that the nature of the mating does influence the progeny is well brought

out by the study of half fraternities, both those in which the father and those in which the mother is the common parent. The economic and other environmental conditions are as similar as possible; the difference in the progeny is therefore the more readily ascribed to the difference in blood. I have collected many of these cases of double matings; and one of them may serve us now as an illustration.

A man whom we may call John Wolley, born 1668, son of a merchant and his wife (sister of the first rector of Yale College), graduated from Harvard College, entered the ministry and finally settled in a church in southeastern Connecticut. He had no brother who survived infancy, but three sisters who married well. This John married twice. His first marriage was to a widow, Martha *née* Silver. About the Silvers of that day I can learn little; they were apparently quiet, steady folk who took no very active part in the affairs of the community. Martha is described in the town minutes as "that eminently pious and very virtuous matron." This couple had 7 children of whom one died at 9 years, leaving 6—4 girls and 2 boys—to grow up. Of the younger son we know only that he was born, married and died, having held the office of deacon. The other brother, at his father's death, removed to a farm five miles back from the village which his father had received as a testimony of regard from the town. In his will the father asked the son to improve the farm (about 500 acres) thus left him. The son lived on the farm, married a woman of no outstanding name, with 23 others founded a church near by, and died at the age of 44 years, leaving 14 children, of whom the eldest was not yet 19. Of these 14 children, 9 were sons and apparently none died in infancy but of all the nine sons there is nothing of importance to note of any except birth, marriage and

death, and except that one son was a lieutenant in the Revolutionary war and died in battle. The eldest of these 9 sons had 2 daughters and 2 sons. All died in early life, except one son who cultivated the farm, built houses with his own hand, married into a good family and had two sons, born 1789 and 1787, who survived early youth and both of whom became quiet, steady farmers, noted for their common sense and contentment.

The Rev. Wolley, born 1668, of Connecticut, married a second time; this time to a daughter of John Morris, of one of the leading families of New York and New Jersey of colonial times—great landholders from which Morrisania, now in the Bronx Borough, New York City, and Morris County, New Jersey, are named, and from this union there were two sons. The elder of them was Benjamin Wolley, graduated Yale College, 1732, and married a daughter of Jonathan Edwards's sister. He held the highest position the town had to offer, represented the town in the state legislature through 25 sessions and was for a time clerk of the house; was state senator for 8 years, and was judge of probate and county judge to his death. During the Revolution he helped organize the army; was one of the committee of safety for the state and was always consulted by Governor Trumbull and General Washington as one of the wisest counselors in one of our most trying days. During a session of the legislature occurred the "Dark Day" of 1780; when it was proposed to adjourn the legislature on account of the impending judgment day, he opposed the motion on the ground that its duty lay in proceeding and asked to have candles brought in. This Benjamin had a brother Thomas who graduated from Yale College, entered the ministry, took part in the "Great Awakening" of Whitfield, showed signs of extraor-

dinary elation, set out on a tour of evangelization, once addressed an audience for 24 hours and then fell into a depressed state. Again elated, he ran into great extravagances, threw suspicion on ministers who did not sympathize with his work, called on the people to commit to the flames jewelry, rings, their best clothing and various books which were listed on his index expurgatorious. He then returned to a more normal state again, renounced his former methods, and lived a quiet life during the 12 years that he survived.

Benjamin Wolley and the niece of Jonathan Edwards had a son, John, graduated from Yale College, 1770, took an influential position in the Revolution; was in congress for 18 years, and held positions on the most important committees. His only brother (Henry), graduated from Yale, 1779, was in the commissary department of the Revolution; was in legislature, court of common pleas, representative in congress, was on the corporation of Yale College and died in his 39th year. Later descendants include leading merchants, manufacturers and inventors.

Note the tremendous contrast between these two sets of half brothers—the quiet farmer and the unknown brother of the first mating; the statesman and unstable but magnetic revivalist of the second. The contrast of the product of these two half fraternities is also striking and serves to show the far-reaching consequences of marriage selection.

Since the nature of the mating is of such profound importance for progeny, a knowledge of genealogical history is of the greatest moment in connection with marriage selection. The presence of highly undesirable positive (dominant) racial traits in the family of either one of a pair of young people who are becoming interested in one another should be known to both.

If they marry and have children in the face of the knowledge that at least half of their children will have the same undesirable trait, perhaps their poignant regrets or the sad example will make it easier for some couples in the next generation to mingle some intelligence with their wooing.

In still another respect a knowledge of racial traits may well be of advantage, and that is in the training of a child. Vegetable seedsmen usually send with their seeds directions as to the specific culture of the particular variety. Now, different children have all the racial distinctness of different kinds of cabbages or melons, and it is unwarranted assumption that they all have the same capacities to be educated and that there is a single course of education that is best for them all. The time is coming, we may trust, when a teacher shall begin a class with something more from the registrar's office than the names of his pupils, when it will be recognized that the teacher can train his pupils the more intelligently and effectively the more he knows about the racial qualities as depicted in the family histories of the individuals he is to train.

So, too, in assisting a young person to decide on a vocation it is now recognized as useful to have an analysis of the traits of the person, as far as they have been developed. But the wise adviser will want to go farther and to study the family history of the young man to see if it may not suggest undeveloped potentialities and thus help in a decision as to the kind of life work he should undertake.

Admitting the value of a knowledge of the presence and distribution of racial traits in a family the question remains: What form should genealogy take in the future to furnish the desired information? Since families are merely collections of related individuals, what is needed is, for as many members of the family as possible, a record

which should comprise not only the usual statements about birth and marriage and also the biographical and social data so commonly found, but, in addition, and above all, physical and mental data including build, proportions, pigmentation, quality of sense organs and other important physical traits, also the mental equipment, tastes for particular occupations, temperament and social reactions. Because of their importance for advice as to the care of the health, the facts of liability to disease, of grave illnesses and of surgical operations should be given and precise cause or causes of death of those who have died. Those individuals who are willing to give more time to their record will find a detailed *analysis of the personality* an absorbing occupation. Guidance in such an analysis may be obtained from the "Outline of a Study of the Self" by Yerkes and LaRue, also from a "Guide to the Analysis of the Personality," by Drs. August Hoch and George S. Amsden, printed in Bulletin No. 7 of the Eugenics Record Office. It takes several hours to make such an analysis and record; but it has to be done only once in a lifetime and perhaps we owe it to posterity to leave behind us such a record. To encourage the making of such records the Eugenics Record Office, at Cold Spring Harbor, distributes free to applicants a schedule which was based in the first instance on Galton's "Record of Family Faculties" and has undergone three revisions. About 20,000 of these schedules have been distributed to individuals, on request. This fact indicates that there is a widespread interest in this country in making a record of family traits.

It is not sufficient, however, that records be made. In order that such records should be of the greatest service to humanity they should be deposited in a central bureau where they are to be kept as confidential

records, but where they will be available in the biological interests of the human race, for both advice in marriage selection and for studying the inheritance of traits. Such a bureau actually exists in the Eugenics Record Office. The obvious necessity of depositing the family history in a central bureau, if it is to be available for eugenical purposes offers for many an insuperable obstacle. They may enjoy recording facts concerning themselves and other members of their family but they could not think of letting them out of their possession. I can sympathize with this feeling. One does not publish the details of one's family history, because, as society is at present constituted, certain of these facts might, if known, interfere with one's standing or advancement in one's social world. This is owing to the presence of scandal-mongers and others of pathological and antisocial instincts who like to hold it up against one that he has certain limitations. The fact that the records are held as confidential ought really to meet this objection. And we may hope that society is nearly ready to take a saner view about one's personal responsibility for one's traits. I am in no way responsible for my racial traits, whether they are due to innate tendencies in development or to peculiar conditions of development, for over neither of these have I, in last analysis, any control. And what a strange spectacle does mankind exhibit, each hiding from others, as far as he can, his personal and family traits, like a lot of little children around a Christmas tree, each hiding from the others the gifts he has received lest it appear that his are not as good as another's. This attitude might be regarded as merely childish and trivial were it not that one's personal and family traits do not belong to oneself, but, in so far as one has, or hopes to have, children and grandchildren, they belong to society.

For each one of us is a mosaic of racial traits that have come from a union of various germplasms in the past and some of which will pass into the germplasms of future generations, and organized society has a right to know the racial qualities of its human breeding stock, for organized society is the only agency to which can be entrusted the guardianship of the quality of the germplasm of the future. The scientific genealogy of the future will afford society that knowledge of the racial qualities of its breeding stock. Thus the value of scientific genealogy to humanity lies above all in this that it will make it possible to utilize a knowledge of the racial characters carried by the individual for the advancement of the race.

CHAS. B. DAVENPORT

COLDSPRING HARBOR, N. Y.,
December 28, 1914

THE EUGENICS MOVEMENT AS A PUBLIC SERVICE

It is coming to be a commonplace statement that we have paid more attention to the production of high-grade breeds of sheep, cattle, swine, and so forth, than we have to that of effective human beings, and this statement gains popular strength as we awaken one by one to the fact that man is, after all, a member of the animal kingdom and subject to its laws. The idea that society should concern itself directly with the improvement of human offspring emanated, as you well know, from Francis Galton, and the movement thus initiated has for some time been known as the eugenics movement. In clearing the ground by way of preparation for actual work, the eugenist has made certain important discoveries. It appears that in many of our civilized populations to-day, the defective classes are increasing more rapidly than any other constituent of the community and that quite aside from the enormous cost that their care entails

upon the public at large, their very growth threatens our civilization with future submergence, if not with annihilation. With this condition confronting us, it behooves us to make every effort to ward off possible calamity, and it has, therefore, become a common duty for us to acquaint ourselves with the nature of the situation, to enquire into such remedies as have been proposed, and to support every measure, both private and public, that gives reasonable promise of staying and correcting an impending evil. In the time allotted to me, it is my intention to bring before you certain aspects of man's nature that seem to me of first importance in establishing a sound basis for passing upon such problems as I have suggested. I shall attempt this from the standpoint of a zoologist, not from that of a eugenicist, for the obvious reason that I am not an expert in the field of eugenics. If I fail in this effort you must lay the blame at the door of the retiring vice-president of Section F, who in his kindly way has trapped me in a moment of unweariness for this occasion.

Although we are awakening to the fact that man after all is only one of the millions of animal species on the surface of the globe, we are also well assured that he is a species of very unusual character. The particular traits in which he differs from most other species are to be found in his social habits. As a community builder, a founder of civilizations, he is far in advance of any other animal. One of the results of his social activities in many communities has been the development of institutions for the preservation and care of his less fortunate fellows. Thus asylums, retreats, hospitals, and so forth, have been established by private munificence or public grants. More or less under the protection of these institutions has grown up a body of semidependents and defectives whose

increase it is that excites the apprehension of the eugenists. That in the past such individuals have always formed a part of our race can not be doubted, but that they ever showed a tendency to increase comparable with what seems to be occurring at present is highly improbable. The occasion of this increase is not, in my opinion, merely the exigencies of modern civilization; it is at least in part due to the immense spread of humanitarian activities which have characterized the last century of our civilization.

That this increase of an undesirable stock should afford an argument against such humane activities is far from my meaning. To my way of thinking this threatening feature is indicative of a minor defect in the workings of modern humanitarianism, and its correction when discovered and applied will, I believe, put that movement on a stronger footing than ever before.

Biologically considered, the situation is described by a simple formula. Most of us have given up the idea that natural selection is a factor of prime importance in organic evolution. Its operations are not detailed enough to yield with any completeness the finished product as we know it in nature, an organic species. But most of us are also thoroughly convinced that selection is a real factor in the development of animals. Its function seems to be that of the elimination of the obviously unfit. As we look about in nature we meet on every side evidences of the ruthless destruction of the strikingly ill-adapted. Among the savage races, as among the lower animals, the defective individual meets an early end. It is only the humanitarianism of our higher civilization that reaches out and protects in a measure such members of our race. Stated biologically then it may be said that we as social beings have devised means whereby the slight effectiveness of natural

selection as seen among most organisms has been measurably checked for certain groups in the human species. Thus a class of individuals with undesirable traits so far as the community as a whole is concerned are beginning to make an alarming showing.

If the increase of defectives is due in large part to a certain restriction of natural selection, is the solution of this problem the reinstatement of that process by a removal of humane protection whereby the defective members of our communities would suffer an early personal removal? Not at all! In my opinion any step in the direction of a curtailment of social help to the defective individual is a step backward. No community can afford such a move. We are at present well enough equipped in our social provisions to extend to such persons a reasonable measure of protection and training whereby they can arrive at the fullness of their slight powers. And such a treatment of them is in my opinion the only right social course. But if society protects them against the attacks of unkind Nature, it is entirely within the rights of society to see that their numbers shall not increase. Such growth may well be the very undoing of society itself.

The increase of such individuals is an organic rather than a social matter; in some cases the defective is the unquestionable product of a disease-laden environment, but in most instances he is the offspring of a defective stock and his present condition is thus chiefly the result of inheritance. Natural selection would eradicate such a class of defectives by the elimination of the individual before he had reached the reproductive period. But society can accomplish this end in a vastly more humane way. It can surround the deficient individual with a reasonable environment and eliminate only his powers of reproduction. Modern biology and surgery have prog-

ressed far enough to make it reasonably certain that sterilization of both males and females may be accomplished with so little initial and subsequent disturbances to the individual, excepting in so far as his reproductive capacity is concerned, that no one can object seriously to this method when legally and humanely employed. Vasectomy in the male and salpingectomy in the female are operations for the removal of the outlet ducts of the reproductive glands and thus by checking the escape of genital products they very usually sterilize effectively the individuals operated upon. They are relatively simple surgical procedures. Since they leave the reproductive glands untouched, they do not involve the important question of internal secretions, and, as might be expected, they have practically no effect on the personality of those subjected to them. They are therefore in every way suited to the purpose at hand. Legislative action looking to their adoption has already been taken in several communities, but it is naturally slow in its accomplishments, for its support requires behind it a certain amount of public opinion that has not yet had time to crystallize. What some of us regard with impatience as over-deliberateness on the part of the public and legislators is undoubtedly due to their ignorance of the seriousness of the actual situation and of the simplicity and effectiveness of the remedies proposed. This part of the eugenics program in no sense contemplates an interference with the liberties of what may be called even a small part of the community. It has only a most limited application. The extent of this application is well expressed by the Whethams in their declaration that "except in the case of the feeble-minded, where state interference is glaringly overdue, probably in the case of hopeless habitual criminals, and possibly in the case of

sufferers from certain types of blindness and deaf-mutism, there is no direction in which, as yet, general interference would be justified." What is sought in this movement is that persons who are such radical defectives through heredity as to be in the nature of public wards should be rendered sterile by as innocuous a means as possible, for, as is well known, such half measures as segregation and the like are too often ineffective. Since society offers a reasonable protection to such individuals, it is, in my opinion, entirely justified in taking this step against those who through irresponsibility would inflict upon it additions to its already too lengthy list of defective members.

But the eugenicist is not only concerned with the problem of a humane elimination of the unfit, he is also equally desirous of perpetuating and increasing the most highly gifted in the community. If the best workers and the best thinkers in all lines of modern human endeavor could reproduce their kind in the next generation to the exclusion of the incompetent and the vicious, civilization would make a stride in less than the span of a single lifetime such as it has never done before. The elimination of the strikingly defective members of society, as I have already tried to show, is a reasonable and a humane possibility. Is it also reasonable to expect that the second part of the eugenics program, namely, the reproduction in future of only the best at hand, is likewise biologically possible?

We can approach this question best by asking what constitutes high excellence in any member of the community. Such a member must have the physical qualifications for an ample life during which he must contribute more or less continuously to the welfare of society. He must be physically intact in that he can withstand the wear and tear of daily exertion, and meet

successfully the strain of momentary crises; and he must cultivate a range of activities that yields products serviceable and acceptable to his community. Modern society has an ample supply of this type of human being and it remains to ascertain the source of his qualities and capacities and the means by which they are handed on to his offspring. The question resolves itself into one of the nature and amount of human inheritance.

On this point the facts gathered from animal breeding are most illuminating. Without this source of information, it would have been almost impossible to have formed any adequate idea of the nature of human inheritance. We know full well that the animal breeder has steadily improved his various stocks and that these improvements have become permanent heritable properties of the particular strains with which he has dealt. We also know that the work of the trained breeder is not a haphazard enterprise, but a well-directed effort in which the constancy of the product can be counted on with ever-increasing certainty. Once well established, a breed will reproduce itself under almost any circumstances with such completeness and fidelity that we scarcely think of the environment as in any way involved and we ascribe the results without further ado to inheritance. To get a Holstein cow we invariably draw from Holstein stock; we do not seek to create Holstein surroundings; and experience entirely justifies this procedure. To be sure, we recognize important effects from the environment. We all know that underfeeding or overfeeding will have an immediate influence upon growth, but we never turn to factors of this kind to change one stock into another. Holsteins are one breed and Guernseys are another, and their immediate characteristics are matters of inheritance, not of environment.

With this kind of information behind us, and with the growing conviction that man too is an animal, we naturally turn to the problem of populating the world with the feeling that if human reproduction were subject to only a little of the kind of control that the expert breeder exerts over his stock, the advance of the human species in social efficiency might be incalculably great.

But here I must invite your attention again and more closely than before to what constitutes an effective human being. Such a member of society is not only a person physically intact and capable of responding to all the requirements of an enormously complex environment, as the best of our domestic breeds do, but he is one who has gathered to himself an untold wealth of experience far exceeding that of any other animal. Moreover, he has not only within himself this vast store of riches, but he long ago devised an immensely complex system of extraneous records in the form of spoken and written languages by which experience could be preserved, handed on to others, and thus made available in a fashion wholly unique. With language came morals, the arts, science, in short all those features that make up civilization. Thus the older naturalists were justified in a measure in regarding man as a species separate from all the rest of creation, and even we must today admit his very unusual character. When we call to mind this vast array of activities so much more diverse, rich and voluminous than that of any other species, the problem of inheritance in man takes on a very different aspect from that in other organisms.

Although very little is known about the transmission of the enormously complex inheritance of human beings, there are in this process two fairly well established features. First, many qualities, some of which

are of a more physical nature like the color of hair or eyes and others of a more functional character like resistance to disease or temperamental conditions, are known to be inherited in man in precisely the same way as the peculiarities of the lower animals are, that is, through the germ. Other possessions, such as language with all its social dependences, are handed on, not through the germ, but by a process of learning, a mode of inheritance which is only most scantily represented among the lower forms. These two types of inheritance, the one characteristic of most organisms, the other more peculiarly human, have gained especial attention in the last few years and have been designated organic and social inheritance, respectively. That they represent distinct and well-defined processes there can be not the least doubt, but what proportion of the total human inheritance is included in each is a matter of much uncertainty.

From the standpoint of genetics these two types of inheritance are of fundamental importance. Organic inheritance is the only kind that can be controlled through the reproductive processes, and its product when normal is the rich natural soil in which civilization flourishes. Social inheritance is the work of the educator, using that term in the broadest sense, and its product when normal is civilization itself. For success it depends first upon a proper organic soil in which to root, and next upon the cultivating influence of a civilized environment. So far as the individual is concerned social inheritance is essentially a process of learning and our whole educational system is devoted to its operations. Since we receive our social inheritance as an acquired character, to use a biological term, and not through the germ, we can be sure that it will never be converted into an organically heritable aggre-

gate. The most we can hope for is that through the operation of organic inheritance, a nervous equipment can be evolved that will enable us to accomplish formal education more effectually and in a briefer time than we do at present, but that the store of facts representing the experience of one individual will ever be transmitted through the germ even in part to another is inconceivable. The future child may receive through the germ increased facility for learning languages, but the words of any particular language can never reach it by this route. They must come to it through the ear or eye, as newly acquired characters, a social inheritance.

With this distinction of organic and social heredity in mind how must we picture the complete process of reproducing effective members of society. Not by purely educative means which often waste themselves on attempts at the improvement of an impossible stock, nor by the exclusive control of reproductive processes which seem to be able at most only to prepare the individual to receive his social heritage, but by a mutual operation of both lines of endeavor. I am aware that there are those who believe that all that society needs for steady improvement is a right alteration in the environment and that reproductive irregularities will then adjust themselves to the improved conditions, and I am also aware that there are others who think that the social control of human reproductive activities will lead most quickly to social efficiency and the environmental changes are without permanent significance. The latter view represents that of the animal breeder pure and simple and would be correct for man were it not that he inherits not only as the lower animals do, organically, but also socially. To distinguish in the daily life of a given individual what is organically inherited from what is social

in origin is very difficult. Has the reformed drunkard become a useful member of society because of the advice he took or by reason of a natural power of resistance received through the germ? No one can tell, but many in this class assert that the advice, the social inheritance, saved them, and no ultra-eugenist has been able thus far to prove that such may not have been the case. With examples of this kind before us, it seems almost impossible to determine whether in human progress organic or social inheritance is the determining factor. And perhaps such a question is in reality futile. Both factors are surely at work in the world and in the infinite succession of events that go to mould a human being into an effective social organism, now one, now the other, probably predominates. Though we are not in a position to give the exact weight that should be ascribed to each of these two factors, we can be sure that the placing of all the weight on one to the exclusion of the other is a mistake. Both factors have shared in the production of effective human beings, and so far as we can see both are likely to continue to participate in this operation.

To conclude, eugenics in the service of society is, in my opinion, entirely justified in demanding the sterilization by humane methods of those defectives who are in the nature of public wards, and this practise may be extended as experience dictates. Eugenics in its relation to propagating the best in the community has a fundamental position in that it is concerned through the elimination of the extremely unfit with the delivery of a reasonably sound stock for cultivation, but it is only secondarily connected with the final production of efficient members of society whose real effectiveness is often more a matter of social inheritance than it is of organic inheritance.

PREPAREDNESS FOR PEACE

AN intelligent and interesting presentation within a brief compass of the subject assigned to me, "Modern Methods of Studying the Mind," would require literary skill of such high order that with the chairman's permission we shall undertake the less ambitious task of considering a few generalizations, not technical descriptions of methods of studying the mind, of the same character as those which John Stuart Mill once described as "the common wisdom of common life"; and then try to determine whether the practical application of some of this knowledge would not to a certain degree remedy our present national unpreparedness for peace with honor.

By way of prologue let me remind you that although at least 100,000 years separate us from our Neanderthal ancestor, we have only just begun to take an intelligent interest in the mechanism of the human mind. Philosophers of antiquity as well as of the present have recorded their impressions of an idealized humanity, but the youngest of all the sciences is the study of the activities of living individuals; and the recent birth of this interest partially explains the pessimism expressed by those who have been rudely awakened by current events to an appreciation of the relatively slight progress made by civilization.

This year marks an important chapter in history. To-day the world pays a tax in blood on human ignorance. Protests are made and Heaven is implored to avert the logical consequences for our failure to obey the command "know thyself." Little did we appreciate how ignorant we are in regard to the foundations of character, and the factors that condition it. As our intelligence increases we shall gradually become quite as much ashamed of our ignorance of human nature as we are now

shocked by the horrors of war. How do we intend to face the present crisis? Indulge in maudlin sentimentality, become more bitterly denunciatory, shut our eyes to the magnitude of the task and pray, or rise and acquit ourselves like men?

The problems of peace are more difficult to solve than are those of war. Intelligent belligerency represents a lower plane of mental activity than intelligent neutrality. A declaration of war is an indication of the present inadequacy of human intelligence to solve great problems. Shall we succeed or fail in our declared neutrality? In what direction shall we turn for assistance? The tax upon the brain power of the nation in preparing for peace will be greater than in preparing for war.

Is it rational to suppose that the correct answers to the great questions which now force themselves upon our attention will be given by diplomatist, statesman, social reformer, historian or any person who attempts to predict coming events merely by analyzing impressionistic records of human conduct? Should we not turn to those who are attempting to secure a comprehensive knowledge of the human brain, and its mechanism as expressed in character and conduct? "Declarations of war" and "treaties of peace" are the products of cerebral functions. As long as physicians attacked the problems of physiology from the historical point of view little progress was made in explaining the functions of individual organs; and equally futile have been the efforts of those who, ignoring the study of living individuals, go back to historical sources for their information and offer "these records of the dead" as interpretations of the synthesized activities of all the organs of the human body objectively represented in behavior or conduct. Is there any reason why we should be spared the ignominy of reaping that which

we have sown? We still look at the problems of living from a narrow historical point of view, describing its phenomena in terms borrowed from post-mortem records. The present tragedy of which we are spectators may in a double sense be called an historical drama, as it marks another one of man's failures brought about in the effort to apply his meager knowledge of the individual to regulate present politics by past history. One of the beneficent results of the application of modern biologic methods to the study of the mind has been the development of a sense of optimism based on the belief that the constantly growing interest in the study of living organisms is a foundation for the hope that human activities, as the laws governing their organization are more clearly revealed to us, may become subject to intelligent control.

Any rational attempt to become a nation more successful in cultivating peaceful arts than in developing a belligerent spirit predicates more thorough preparation than man has made to undertake the study and control of the mental mechanisms which give rise to obsessions, overvalued ideas, anomalous emotional reactions, jingoism and chauvinism. Never before has there been a greater necessity than the present one of extending our knowledge of the laws governing the activities of the mind. Temporary expedients for the preservation of the world's peace may be suggested by tribunals, senates and parliaments, but hope for the successful and peaceful solution of problems of vital importance to humanity depends primarily upon the success of man's efforts to attain a comprehensive knowledge of his own brain-power, and the methods by which this may be generated and controlled.

Among the signs of the times are evidences of a sentimental desire for peace, but on the other hand there are reasons for

doubting whether our brain power is sufficient to attain and maintain conditions that are unfavorable for war. The enumeration of some of our national characteristics give rise to premonitions that in this crisis we shall with commendable promptitude and efficiency discharge our duties to sufferers abroad; and at the same time show an extraordinary disregard for the intelligent direction of many affairs at home. As a people we undoubtedly work best when under the strain of emotional excitement, and this tendency justifies great deliberateness in considering whether we are equal to the task requiring limitless stores of patience and an intelligence sufficiently developed to bring about conditions essential for the preservation of peace. In the interests of humanity it is desirable to distinguish very clearly between the logical thought-processes of intelligent, peace-loving people, and the sentiments of those who declaim against the horrors of war. There are certain innate qualities of the American mind which justify more than an occasional jog to our memories in order to recall the fact that intellectual judgments are largely determined by the character of the underlying emotional reactions; and yet without attempting to organize feeling or sentiment we complacently direct attention to our traditional capacity to look at the problems of life from a very practical point of view, and remain oblivious to the danger that exists in the constant repression of the sentimental side of our natures until some crisis increases the tension to such a degree that equilibrium can only be restored by an explosion.

We shall not be guilty of carrying our methods of introspection too far if we refer to the serious handicap to the cultivation of those qualities of mind which predispose toward the peaceable solution of im-

portant questions that is expressed in the national disregard for the biologic importance of good mental habits. We seldom stay at one task long enough to develop the habits essential for efficient and thorough work, and the same amateurishness characterizes our efforts whether they be in the field of diplomacy, road-building or in organizing a university. If we actually determine to lay substantial and rational foundations for peace, and not erect a temporary structure on the shifting sands of sentiment we should look below the surface for evidences of actual progress towards the realization of these aims; and find them expressed in such an undertaking as the endowment and organization of a great institute for the study of the brain and nervous system, in increased provisions made for research along similar lines in our universities, and in the establishment of departments of education with a view to training teachers to recognize the biologic needs of human beings; as well as in all those rational efforts made to extend or to put into practise our knowledge of the mechanisms by means of which human individuals adjust their lives successfully to the environment in which they live.

The folly of the mariner who goes to sea without a compass is not greater than our own in attempting to solve the problems involving the destiny of our race without any more definite knowledge than is yet possessed of the functions of the brain and nervous system. The optimistic views expressed by the eugenist in regard to the intellectual progress of the human race that will be brought about by selective breeding will be more rapidly realized as soon as we have collected sufficient data concerning the functions of the nervous system to determine what the desirable mental mechanisms are; as well as the nature of the factors conditioning the trends

of the mental life. In reading history our attention is chiefly focused upon the behavior of large numbers of human beings, the crowd or mob, and we forget that the activities of the masses can not be interpreted intelligently until the reactions of the individual have been analyzed. History and anthropology can only become vital subjects and potent factors in directing the streams of civilization when interpreted by a more complete knowledge than we yet possess of the intricate mechanisms of the human brain. It is unnecessary to call attention to the fact that the accounts of man's interest in the investigation of hypothetical mental qualities are voluminous, whereas, the records of actual study of the minds of living persons are comparatively few and meager.

The progress made in the study of mental phenomena has been along two general lines. The different organs composing the human machine and their relations to each other have been made the subject of investigation, and in the second place by observation and by carefully gathering experience as to how the machine expresses its activities as a unit in behavior and conduct, a profitable and broad field of enquiry has been opened up. So dominated are many of us by the instinctive tendency to worship at a special shrine or bow down before a fetish that the absence of test-tube or induction coil in studying the problems of human conduct often leads to the supposition that the laws governing mental phenomena are less easily recognized than those conditioning the reactions taking place in a beaker or registered on a kymograph cylinder.

If we turn from trying to estimate the conjectural benefits that might follow the extension of knowledge of the brain to find some practical application for the relatively few facts already brought to light,

we shall be surprised that even this limited store of information has not been put to some practical use. Even in scientific laboratories by utilizing this information the conditions under which research is carried on could be greatly improved. Progress would be more rapid if scientific men estimated successful achievements not only by counting the number of new facts discovered by an investigator, but by measuring the dynamics of human nature and the character of the mental processes by which investigators attained their results. Occasionally the scientific atmosphere becomes so oppressive that we are justified in taking precautions so that anomalous emotional reactions, cynicism, moods of depression and exaltation, over-valued ideas, obsessions, paranoid trends of thought and the maniac's capacity for indulging in invective and controversy, as well as in depreciating the achievement of other persons, may be replaced by more desirable mental mechanism.

The importance of the early formation of desirable mental habits is a principle reiterated so often that it makes many moments unhappy ones during the copy-book age, but the practical application of the doctrine to increase our happiness and efficiency in living is almost ignored by the present educational system in America. A system of education based upon the vital principle that success in living should be measured by the ease with which the human machine works, and not by the amount of cargo stored in the hold, would be of incalculable benefit to our race.

No more effective demonstration that science is common sense at its best is needed than the justification derived from the modern methods of studying mental phenomena of making habit-formation the chief function of elementary teaching, and from this procedure follows a natural and not

arbitrary division between school and university; the former would then be recognized as the place in which habit-mechanisms are carefully trained, and the latter a field for trying out under supervision the activities essential for independent thinking, and for offering encouragement to competent persons to contribute to the extension of human knowledge.

If the citizens of this country are animated by a sincere desire to maintain a condition of peace expressing the activities of virile manhood and not the idle dreams of those who are unable to protect themselves against aggression, a well-directed effort should be made to assist those potentially capable of intellectual leadership to develop their mental faculties to the maximum of efficiency. Although leaders of thought may now be classed as among the actual necessities of life, the atmosphere of the American university is distinctly favorable for the growth of dilettantism and mediocrity. These institutions suddenly find themselves called upon to do their share in bringing about a readjustment of civilization hampered by an organization continually modified to meet either the demands of alumni, who for purely sentimental reasons are disinclined to aid actively in carrying out the proposed transformation of college into university or the increasing number of protestations coming from the champions of a hysterical athleticism. The measure of our intelligence as well as capacity to control effusive sentimentalism may be readily gauged by the methods we adopt in attempting to transform the universities into centers from which a spirit of intellectual leadership may be disseminated.

One result of "the splendid isolation" of our universities from each other has been that a chain of fictitious values for both ideas and ideals is established that empha-

sizes to an excessive degree the importance of a single institution and fails to bring home to students the desirability of developing emotional reactions in connection with permanent motives. At an impressionable age the emotional life of college students is sharply focused upon the interests of a single institution and the general drift of the affective undercurrents is so rigidly determined as to make it exceedingly difficult for the individual later in life to cultivate a just sense of discrimination. The dynamic power of constructive imagination depends upon the organization of an individual's activities, so that there should be coordination of feeling, sentiment and volitional response; and it is just this principle upon which so much of the effectiveness of our intellectual efforts depends that is practically not represented in the organization of our universities; and the failure to make this provision often deprives this country of the fruits of the highest forms of intellectual activity.

Mental habits once established, and motives called into play can not as a rule be shifted later in life without seriously restricting the intellectual horizon by the forcible readjustment of the emotional balance; an adaptation which is none the less serious because the individual is not aware of the process. As long as universities are controlled largely by their own alumni and by boards of trustees representing the traditions, beliefs and parochialisms of a single institution it is hardly possible that these institutions will become centers in which the type of personality essential for creative effort in science, art, or literature will receive a hearty welcome or attain full citizenship. The influence of the continental university is often unfortunately restricted by racial prejudice and national boundaries, but the American university is pretty generally hemmed in by

the much narrower parochialism of its own alumni.

May we not begin to let a little more oxygen into the university atmosphere so that the energy, enthusiasm and idealism of American life which is already being put to a world test may be wisely directed and not repressed or stifled. Harvard's Back Bay traditions, Yale's fixed belief in the value of New Haven's ideals, Columbia's complacent metropolitanism, Princeton's faith in imported culture, and Pennsylvania's homing instincts all mark commendable mental traits that have served a useful purpose; and probably these qualities would once again become active ferments if they were transferred to new media.

The following plan if carried into execution would probably tend to bring about conditions more favorable than those now existing for the liberation of the energy stored up within our universities, and which is so often wasted without any effort made to convert it into a creative force.

If each university tried the simple experiment of appointing a small number of consulting trustees, members of the faculty of rival institutions, to meet once or twice a year with the home-board they would bring into the discussion of academic problems that sense of perspective and of values which is now so feebly represented; and definite progress would also be made in preparing intelligently both to maintain peace and deserve respect. This change would be the equivalent of a public declaration of intentions to the effect that the universities were prepared to abandon their local traditions and prejudices, to substitute for particularism a sense of nationalism or even a broad world-spirit, and thus they would become more intimately identified with the intellectual life and spirit of our civilization; and then in good time, following the growth of these broader

interests, more intelligent sympathy and active support would be accorded to those who are endeavoring to extend the bounds of knowledge.

In the present world-crisis we are oppressed by the feeling that the old conceptions of truth have failed us, but our despondency is lessened by the realization of the progress which the efforts of investigators must bring when they are heartily approved, sustained and strengthened by universities fully awakened to the necessity for intellectual leadership in the development of the newer civilization.

STEWART PATON

JOHN MUIR

On the day before Christmas John Muir, geologist, explorer, naturalist, author, joined the great majority. Though seventy-six years old there had been no apparent decay of his remarkable faculties. Nor was there any painful waiting for the end. Death found him almost in the midst of his literary activities, which he had laid aside for a brief interval in order that he might spend the Christmas holidays with one of his daughters in southern California. On the 27th of December a large concourse of friends gathered from near and far at his home near Martinez, California, to hear the last rites spoken over his remains. He was buried, beside his wife, under trees planted by his own hand, in the beautiful family burial-ground among the Alhambra hills.

John Muir was born at Dunbar, Scotland, April 21, 1838. He was the third in a family of seven children. His early education was received at the grammar school in Dunbar. When he was eleven years old his father emigrated with his family to the United States. They settled on a farm near Portage, Wisconsin. There he indulged to the full his fondness for the life of the wilderness. His book entitled "The Story of My Boyhood and Youth" gives a pleasing picture of this period of his life. He also developed an extraordinary aptness for mechanical inventions of

various kinds. Some of these are described in the same volume. In due time he went to the University of Wisconsin. His university career is best described in his own words: "Although I was four years at the university," he wrote two years ago, "I did not take the regular course of studies, but instead picked out what I thought would be most useful to me, particularly chemistry, which opened a new world, and mathematics and physics, a little Greek and Latin, botany and geology. I was far from satisfied with what I had learned, and should have stayed longer. Anyhow I wandered away on a glorious botanical and geological excursion, which has lasted nearly fifty years and is not yet completed, always happy and free, poor and rich, without thought of diploma or of making a name, urged on and on through endless inspiring, Godful beauty."

It was in the early sixties that Muir started off on those wanderings that finally brought him to California. In the early seventies his first brief communications on Yosemite and the Sierra Nevada began to appear in San Francisco and eastern papers. Soon his articles began to be published in the *Overland Monthly*, *Harper's*, *Scribner's*, the *Century*, and the *Atlantic*. A *Reference List to the published writings of John Muir*, prepared by Professor Cornelius B. Bradley in 1897, contains the dates and titles of nearly one hundred and fifty such articles and communications. At that time he had published only one book, "The Mountains of California," which appeared in 1894. But in "Picturesque California," edited by him in 1888, he had contributed articles on "Peaks and Glaciers of the Sierra," "The Passes of the High Sierra," "Yosemite Valley," "Mt. Shasta," "Washington and Puget Sound," and "The Basin of the Columbia River." In the *Proceedings of the American Association for the Advancement of Science* he was represented by papers on "The Formation of Mountains in the Sierra" (Vol. XXIII.), and "The Post-glacial History of the *Sequoia Gigantea*" (Vol. XXV.).

It seems remarkable now that a man of such

outstanding ability as a naturalist and a writer should not have published his first book until he was in the fifties. But Muir found himself very gradually. He spent long periods in exploring and living among the mountains of the Sierra Nevada. On these trips he endured many hardships and fared very frugally. He made copious notes of all his observations and accompanied them with surprisingly exact and often beautiful drawings. His studies were chiefly of a geological, botanical and physiographical nature. The extent and effects of glaciation in the Sierra Nevada received his particular attention, and he was first among geologists to work toward conclusions, on this subject, which in more amplified form now hold the field.

John Muir was an inveterate traveler. During his earlier years he went on foot through parts of the southern states and Canada. In 1876 he had become a member of the U. S. Coast and Geodetic Survey and visited Alaska, where he made many canoe trips and explorations. The great Muir Glacier, which he discovered, bears his name. In 1878 he visited the Arctic regions on the U. S. *Corwin* in search of the De Long expedition, and in 1899 became a member of the Harriman expedition to Alaska. In 1903-4 he visited Russia, Siberia, Manchuria, India, Australia and New Zealand. In 1911 he made a trip up the Amazon in South America, and he went to Africa in 1912. All these travels were undertaken for purposes of study primarily, and served to enrich still further his large stores of knowledge.

The publication of his book on *The Mountains of California* made him known to the world as a writer of exceptional power. His vivid, easy, poetical style was wrought out slowly and with great care. He refused to be hurried in his work, and rewrote his chapters a dozen times if he thought he could improve them in point of expression. His second book, "Our National Parks," shows his literary style at its best. It appeared in 1901 and reflects his eager activity in the interest of forest preservation and the establishment of national parks and reservations. This was

followed by "Stickeen, the Story of a Dog," 1909; "My First Summer in the Sierra," 1911; "The Yosemite," 1912; and "The Story of My Boyhood and Youth," in 1913. A book on his Alaskan explorations was practically completed at the time of his death.

A number of high academic honors came to Mr. Muir in his later years. Harvard University bestowed upon him an honorary M.A. in 1896; the University of Wisconsin an LL.D. in 1897; Yale University a Litt.D. in 1911; and the University of California an LL.D. in 1913. He was one of the founders of the Sierra Club, in 1892, and its president for twenty-two years. The outings for which this organization has become famous were due to his initiative. At the time of his death he was president, also, of the Society for the Preservation of National Parks, and vice-president of the California Associated Societies for the Conservation of Wild Life. It should be noted, too, that he was a member of the Pacific Coast Committee of the American Association for the Advancement of Science, charged with the task of preparing for the San Francisco meeting in 1915.

In the death of John Muir the world has lost one of the most remarkable men of our time. To the last he preserved the eager interest of a child in all the phenomena of nature. His unaffected simplicity and modesty remained unchanged, though fame literally wore a path to his door. He knew how to translate his enthusiasms into human benefits, for no American citizen did more for the establishment of national parks, and the conservation of the great forests of the west. In the concluding chapter of his book, "Our National Parks," his sentences are aflame with the passion of a Hebrew prophet who sees the vision of the coming age and its needs. It may be that the present generation is able to appraise justly the services of John Muir as a naturalist and explorer. John Muir the seer, the writer, the father and guardian of Yosemite, awaits the appraisal of a later and greater day.

WILLIAM FREDERIC BARD

SCIENTIFIC NOTES AND NEWS

CHARLES EDWIN BESSEY, head of the department of botany and head dean of the University of Nebraska, distinguished as a leader in botanical research and education, past president of the American Association for the Advancement of Science, died on February 25, in his seventieth year.

ARTHUR VON AUERS, the eminent German astronomer, has died at the age of seventy-six years.

DIRECTOR W. A. CAMPBELL, of the Lick Observatory, president of the American Association for the Advancement of Science, has been elected a foreign member of the Swedish Royal Academy of Sciences, Stockholm.

THE William H. Nichols medal is to be conferred on March 5 on Dr. Irving Langmuir, of the research laboratory of the General Electric Company, at the meeting of the New York Section of the American Chemical Society. Dr. Langmuir will make an address on "Chemical Research at Low Pressures."

ON the occasion of the inauguration of Dr. R. B. von Klein Smid as president of the University of Arizona, the degree of doctor of laws was conferred on Dr. D. T. MacDougal, director of the department of botanical research of the Carnegie Institution, and on Dr. J. W. Fewkes, of the Bureau of American Ethnology.

DR. JOHN C. MERRIAM, professor of paleontology in the University of California, has been appointed to be chairman of a sub-committee on research work on the Pacific coast established by the committee of one hundred on scientific research of the American Association for the Advancement of Science.

DR. W. H. HADOW, principal of Armstrong College, Newcastle-upon-Tyne, and Sir Henry J. Oram, engineer-in-chief of the British fleet, have been elected members of the Athenæum Club, for distinguished eminence in science and public service.

DR. ADELAIDE BROWN, of San Francisco, has been appointed a member of the California State Board of Health, to succeed Dr. O. Stansbury.

DR. LEWELLYS F. BARKER, professor of medicine at Johns Hopkins University, Baltimore, was the guest of honor at the thirty-third annual banquet of the McGill Medical Society, Montreal.

DR. H. P. ARMSBY, director of the Institute of Animal Nutrition of the Pennsylvania College and Station, has been relieved of all undergraduate instruction and will devote his entire time to research in animal nutrition and to advanced graduate instruction.

THE board of trustees of Stanford University has elected to its membership Dr. Ralph Arnold, of Los Angeles, a graduate of the university, and has reelected Mr. William Babcock, a capitalist of San Francisco, and Mr. Charles P. Eells, a lawyer of San Francisco, whose terms recently expired. Dr. Arnold is the second alumnus on the board at the present time, the other being Mr. Herbert C. Hoover, who is now serving as chairman of the Belgian Relief Commission in London. Dr. Arnold graduated from the department of geology at Stanford in 1899, received his A.M. there in 1900, and his Ph.D. in 1902. For a number of years he was engaged in scientific work for the government, being for a time paleontologist of the Geological Survey and later in charge of the survey's oil investigations in California. For the last half dozen years Dr. Arnold has been engaged in private practise in the oil fields of the United States, Mexico and South America. He has recently been withdrawing from technical work to a considerable degree in order to devote himself more fully to research work in the field of paleontology.

MR. A. F. MEYER, associate professor of hydraulics in the University of Minnesota, visited Toronto in February to confer with Mr. Arthur V. White and appear before the international joint commission in connection with the Lake of the Woods investigation. Mr. Meyer is serving this commission as consulting engineer.

MR. JOHN BLACKSTOCK HAWLEY (Minnesota, '87), consulting engineer of Fort Worth, Texas, has been elected president of the Texas

Association of the Members of the American Society of Civil Engineers. At the recent annual meeting of the society Mr. Hawley was elected director.

DR. T. C. CHAMBERLIN, head of the department of geology in the University of Chicago, and formerly president of the University of Wisconsin, gave a series of lectures in the department of geology of the University of Wisconsin from February 15 to 19, in which he reviewed the Chamberlin-Moulton planetesimal hypothesis of the formation of the solar system, with reference especially to recent work in correlating terrestrial phenomena in the light of this theory. On February 18, Dr. Chamberlin gave a public lecture under the auspices of the Science Club of the University of Wisconsin on "Early Stages of the Earth's History."

DR. FRANCIS H. HERRICK, professor of biology in Western Reserve University, addressed by invitation the legislatures of the state of Maine, on February 25, on the subject of "The Preservation and Propagation of the Lobster."

DR. GRAHAM LUSK, professor of physiology in the Cornell Medical School, recently delivered before the Washington University Medical School two lectures entitled "The Basis of Animal Calorimetry" and "Metabolism in Diabetes."

SIR CHARLES AUGUSTUS HARTLEY, the distinguished British engineer, died on February 22, at the age of ninety years. Sir Charles devoted most of his career to hydraulic engineering and the improvement of estuaries and harbors for the purposes of navigation. In 1875 he was one of the committee appointed by the authority of Congress to report on the improvement of the Mississippi. In 1884 the British government nominated him a member of the international technical commission for widening the Suez Canal. He was a member of the congress that sat at Paris to decide on the best route for a ship canal across the Isthmus of Panama. He was engineer-in-chief and consulting engineer to the European commission of the Danube from 1856 to 1907.

As was noted in *SCIENCE* several months ago the California Fish and Game Commission is attempting to build up public sentiment as the most efficient means of conserving game. In pursuance of this policy the commission has begun the publication of a quarterly, *California Fish and Game*, which is designed to bring facts regarding game and game conditions to the people of the state. The motto of the publication is "Conservation of wild life through education." The second number of the periodical has just been issued. It contains articles relating to game in California, with departments for editorials, fishery and hatchery notes, conservation in other states, life histories of game birds and mammals, and the relation of wild life to agriculture. Full reports on the work and the monthly expenditure of the California Fish and Game Commission are also given. Dr. Harold C. Bryant, director of the newly formed bureau of education, publicity and research is editor of the periodical.

It is stated in *Nature* that in answer to a question as to typhoid in the army, asked in the House of Commons on February 8, Mr. Tennant, Under-secretary of State for War, said: "Of the 421 cases of typhoid in the present campaign among British troops 305 cases were in men who were not inoculated within two years. In the 421 cases there have been thirty-five deaths. Of these deaths thirty-four were men who had not been inoculated within two years. Only one death occurred among patients who were inoculated, and that man had been only inoculated once, instead of the proper number of times—namely, twice." Replying to criticisms against inoculation made by Mr. Chancellor in the House of Commons on February 9, Dr. Addison pointed out that in the South African war there were 58,000 cases of typhoid—more than an Army Corps—whereas in the great force now in France and Belgium, and after six months, including three months of atrocious weather, there have only been 421 cases among the troops. The total losses in South Africa were 22,000, of which about 14,000 deaths were from diseases and 8,000 of these were from typhoid.

THE *British Medical Journal* states that the hospitals of Canada have been severely affected by the war, and in Montreal it seemed as though the three principal hospitals might have to close their doors. A campaign among the 800 governors of the General Hospital produced \$150,000 in two days, sufficient to meet expenses for the next two or three years. The appeal for funds for the Notre Dame and Western Hospitals has been equally successful, and they will remain open at least for some time to come. In Vancouver the staff of the General Hospital have voluntarily agreed to a reduction of from 5 to 10 per cent. in their salaries in order to help the board in its financial difficulties.

ON April 3, 1915, an examination will be held to provide an eligible list for the position of food bacteriologist in the Chicago office of the State Food Commission. The salary at present is fixed by law at \$1,800 a year. The limits recommended by the State Civil Service Commission are \$150 to \$175 a month. The examination will be open to non-residents, as well as residents, of Illinois over twenty-five years of age. The duties of the position involve making bacteriological examinations (and interpreting the results of such examinations) of milk, ice cream, eggs, meat, tomato products, etc., in accordance with the dairy, food and sanitary laws. The applicant should be able to state his opinions briefly and accurately as he may be called upon frequently as a court witness. Education equivalent to graduation in science from a college of recognized standing is required, as well as some knowledge of anatomy, histology and pathology, and some training in animal experimentation. The statement is made from the State Food Commissioner's office that the person employed in this position will be given time to take work in the various medical schools or universities of Chicago so that he may acquaint himself with those subjects with which he is not thoroughly familiar.

ANNOUNCEMENT is made of the establishment for the year 1915-16 in Nela Research Laboratory, National Lamp Works of General Electric Company, of two fellowships in phys-

ical research to be known as the "Charles F. Brush Fellowships." These fellowships are offered for the coming year through the generosity of Mr. Brush who desires thereby to stimulate interest in industrial physics and to make it possible for young men to undertake research work in physics in the environment of an industrial plant. The Nela Research Laboratory will provide space and all necessary facilities, and will have general supervision over the investigations, which must be consistent with the normal activities of the laboratory.

FIRE in the national forests of the west in 1914 caused a loss to the government of not quite 340,000,000 board feet of merchantable timber, valued at \$307,303, and of reproduction, or young growth of trees, valued at \$192,408, according to statistics just compiled by the forest service. There were 6,805 fires, of which only 1,545 burned over an area of ten acres or more. About 77 per cent. of all the fires did damage of less than \$100 each. In addition to the losses suffered by the government, timber on state and private lands within the forests, totaling 228,008,000 board feet and valued at \$175,302, was lost. The total area burned over was 690,240 acres, of which 310,583 acres were state and private lands. Notwithstanding that it was an exceptionally favorable year for fires, on account of high temperatures, heavy winds and prolonged drought, the average loss per fire was \$103, as against \$131 in 1911, when there were only about half as many fires. Eighty-five per cent. of the total loss was caused by fires in Idaho, Montana, Oregon and Washington, where more than half the timber in all the national forests stands. Less than one tenth of one per cent. of this timber was affected. Of the 6,805 fires reported, 3,691, or 55.9 per cent., occurred in these states, and of the 99 fires causing losses of more than \$1,000 each, 81 were in this region. Lightning was the chief cause, starting 2,032 fires; campers came next with 1,126, followed closely by railroad locomotives, with 1,110. Incendiaries lighted 470 and the rest were attributed to brush burning, sawmills, etc., or their origin was unknown.

UNIVERSITY AND EDUCATIONAL NEWS

THE committee on education of the House of Representatives has reported favorably a bill establishing a National University in Washington. According to the bill an initial appropriation of \$500,000 would be made. The university would be devoted to research and graduate work and no degrees would be conferred.

IN its annual report to the board of education of New York City, Superintendent Maxwell urges the need of appropriating ten million dollars for elementary school buildings in order that all children may be accommodated. There is also said to be immediate need of buildings for high schools and for vocational schools.

ESTIMATES for 1915 appropriations for the Massachusetts College and Station have been submitted for \$313,300 for maintenance and additional appropriations as follows: Microbiology laboratory, \$87,500; for the completion of the agricultural building, \$123,500; new dormitory, \$40,000; enlargement of the power plant, \$30,000, and minor improvements, \$10,000.

IN view of the difficulties of foreign travel no fellows will be appointed by the Kahn Foundation for the year 1915-16.

DR. HORACE GROVE DEMING, for the past three years associate professor of chemistry in the Philippine College of Agriculture, has been appointed professor of chemistry and chief of the department in the University of the Philippines, filling the vacancy occasioned by the death of Dr. Paul Caspar Freer.

DR. ANDREW HUNTER, formerly assistant professor of biochemistry in Cornell University, has resigned the position of biochemist, U. S. Public Health Service, in order to accept the chair of pathological chemistry in the University of Toronto.

DISCUSSION AND CORRESPONDENCE

THE HISTORY OF SCIENCE

TO THE EDITOR OF SCIENCE: I desire to express my hearty commendation of Dr. Libby's

paper in the "History of Science," published in SCIENCE for November 8, 1914. His paper is one of the pioneers in this new and interesting field of thought, and the expression of such ideas needs further encouragement.

It is apparent that the time is fairly well upon us to give some definite consideration to the value and place of the study of the "History of Science," in the curricula of our universities, colleges and technical schools.

That this study represents a strong reactionary movement from the over-materialistic and specializing tendencies of the age in all departments of human progress is evident, and this is especially true in the sciences themselves. This reaction finds its development in the present idealism in the German school of science, where the historical method in the study of the sciences, theoretical and empirical, has been practised.

Two other notable and interesting papers in the past have contributed valuable suggestions, emphasizing two essential pedagogic points of view. The first treated the cultural or intellectual values derived from the intimate understanding of the problems of nature through the scientific method, and the second the historical perspective in the study of the sciences. Dr. Geo. H. Mead,¹ of the department of philosophy, lays special emphasis upon the cultural aspect in the history of science. In the last paragraph of his article he says:

There is certainly no agent that can carry more profound culture than the sciences, but our science curriculum is poor in what may be called cultural courses in the sciences, and the import of science for culture has been slightly recognized and parsimoniously fostered.

The value and importance of history as a subject, and as a method, in the ordinary culture courses can not be denied; therefore the study of nature or science with the historical basis is equivalent to a power twice as great. And when education as an instrument of progress emphasizes the cultural element, education then becomes a potent force in making and maintaining the civilization of the future.

¹ SCIENCE, N. S., Vol. XXIV., September, 1906, pages 390-97.

The second paper, by Professor C. R. Mann,² of the education department in the University of Chicago, advances the historical method in the teaching of science, and the fruitful consequences to be brought about.

Some few years ago the writer undertook a study similar to that of Dr. Libby regarding the value of the history of science for the undergraduates of our colleges, and the replies which came from many prominent men in science, education and philosophy were most encouraging. These letters brought forth a universal affirmative reply regarding the value, importance and the future of the subject, and in general substantiated the arguments of the three papers named. To quote from a letter of Dr. Libby, in which he quotes from some one in authority, "the history of science is the very next essential thing in the development of technical education." Possibly the progress has been slow because there exists no satisfactory text-book on the subject in this country. Professor Tyler and Professor Sedgwick,³ of the Massachusetts Institute of Technology, throw a much needed and encouraging ray of light to workers in this field.

In this country at the present time a number of our universities, colleges and technical schools are offering history of science courses in one way or another. Foremost of these are the universities of Chicago, Harvard, Michigan, Columbia, California, Stanford and the Massachusetts Institute of Technology. There are apparently two types of courses in the history of science, or two methods in treating the subject, namely, the history of a single subject such as physics, chemistry, etc., which is found in most schools; the second type is represented by the course given at Harvard. This is a general or combined course, three hours through the year being divided into physical and biological sciences. This is also conducted as a separate group of studies, thereby giving it more value or importance, and has now been offered for four years by

²"The History of Science, An Interpretation." *Popular Science Monthly*, Vol. 72, April, 1908, pages 318-22.

³"The Teaching of the History of Science," *SCIENCE*, January 1, 1915, pages 26-27.

Dr. L. J. Henderson, of the chemistry department. Personally, I believe it is the most satisfactory method in treating such a study as a course, although it depends upon the point of view one takes.

The University of Chicago offers in addition to its separate historical courses of individual sciences, a series of courses in the department of philosophy on the history and development of ancient and modern scientific concepts, which is apparently closely allied to the history of science.

The writer is at present preparing a paper upon the "Present Status of the Teaching of the History of Science in Our Universities, Colleges and Technical Schools." This study will involve a statistical account and comparison of the different courses given in the history of science, the number of hours of lectures, method of treating the course, and other facts bearing upon the tendencies and progress of this subject.

It is encouraging to note that while the bibliographical material upon this subject is very meager, in this country at least, yet sufficient has been accomplished to enable a fair beginning to be made for a working basis. The John Crerar Library, Chicago, has done more than any other agency in developing this important phase. Of course there are a number of foreign bibliographies or catalogues, such as *The International Catalogue of Scientific Literature*, London, *Institute International de Bibliographie* (science section), Zurich, *Bibliographie der Deutschen Naturwissenschaftlichen Literatur*, Berlin, and the *Bibliotheca Mathematica, Zeitschrift für Geschichte der Mathematischen Wissenschaften*, Leipzig.

In France the Paris Academy of Sciences offers each year a prize of two thousand francs for the best essay, memoir or book, original or translated, upon a general or specific subject in the history of science. The most notable instance was when in 1911 the Prix Binoux was awarded to M. Antonio Favaro, the great Italian historian of science, for the publication of the works of Galileo Galilei, and to M. Edmond Bennett for his "Notes and Memoirs Relative to the History of the Sciences."

It is to Germany, however, that the most credit belongs for the development and the work in this field. The number of very excellent texts and treatises in the history of science in Germany is far beyond the production in any other country. German scholarship is here again manifested in both quantity and quality, and Der Deutschen Gesellschaft für Geschichte der Medizin und Naturwissenschaften, organized in 1902, Leipzig, is probably the only organization devoted to the study and fostering of the history of science. The *Mitteilungen* contain a most complete and valuable bibliographical record of articles, memoirs and books in print, also containing originals and translations of historical treatises in science.

Two other publications worthy of notice at this time are the *Archiv für die Geschichte der Naturwissenschaften und der Technik*, Leipzig; and *Isis, Revue Consacrée à l'Histoire de la Science*, published in Belgium (or was published).

In closing, it would seem that in order to lend encouragement and force to aid this new field of investigation great good ought to come from an organization of a section in the American Association for the Advancement of Science, known as the History of Science section.

FREDERICK E. BRASCH

STANFORD UNIVERSITY,
January 16, 1915

SCIENTIFIC BOOKS

The Home of the Blizzard, being the Story of the Australian Antarctic Expedition, 1911-1914. SIR DOUGLAS MAWSON, D.Sc., B.E. J. B. Lippincott Co. Illustrated, also with maps. \$9.00 net.

It was thought by many that the acme of antarctic interest had culminated in the record-breaking sled journeys of Shackleton, the attainment of the Pole by Amundsen, and especially in the pathetic tragedy of Scott's latest expedition. It is encouraging to find in the records of Mawson's non-pole hunting explorations novel lines of human endurance, of tragic disaster, and of historical reversion,

combined with scientific researches of value to the world. These physical and moral results exacted from the explorers not only the fullest effort of body and mind, but they also obliged the chief, returning as by miracle from death, to face a deficit of nearly \$40,000 to pay for his privilege of polar service.

Mawson's expedition, which had the financial support of the Australasian governments, looked to the exploration of antarctic lands in the Australian quadrant—from 90° E. to 180° E.—and their occupancy for scientific observation and research. An intermediate station, wireless equipped and weather observing, was established on Macquarie Island, 850 miles south-southeast of Hobart. Circumstances restricted the parties for the continent of Antarctica to two—the main base at Commonwealth Bay, 87° S., 143° E. occupied by Mawson and 17 men, and the west base on the Shackleton Oceanic Icecap, 66.7° S., 97° E., established by Dr. Frank Wild and 7 men, in January, 1912.

Scientific work was carried out along the principal lines of geographic exploration, geology, biology, meteorology, glaciology, oceanography and magnetism.

Geographic Exploration.—From Mawson's base journeys aggregating 2,400 miles were made, in which King George V. Land was discovered and explored between 138° and 152° E., and from 87° to 70° 30' S. In one journey a névé bridge broke and Lt. Ninnis with team and sledge were fatally precipitated into a crevasse hundreds of feet deep, where they disappeared from sight. Mawson and Dr. Mertz were thus stranded over 300 miles from the station, with 6 wretched dogs and food for a week. Manfully accepting the situation, they struggled amid blizzards over frightfully rough ice, killing and eating their dogs as they failed to work. Mertz died of exhaustion 100 miles from home, towards which Mawson struggled in the last stages of bodily weakness, escaping as by miracle through an indomitable will, physical endurance and the finding of a chance cache set up by a search party. From the western base Wild's party discovered and explored Queen

Mary Land, between 101° 30' E., and Gaussberg, Kaiser Wilhelm II. Land, in 88° 45' E. By ship and sledge the coast was traced through fifty-five degrees of longitude, and with previous discoveries it is now certain that the continent of Antarctica extends continuously from 86° E. eastward to 158° W. longitude.

At sea Captain Davis discovered Mill Rise, a submarine ridge in about 47° S., south of Tasmania, and Jeffrey Deep, varying from 2,500 to 3,100 fathoms, approximately between 36° to 46° S., and from 110° to 125° E. He also located the continental slope of Antarctica through 55° of longitude.

Magnetism.—Besides regular work at the base stations, field observations were made by each sledge party. The strenuous effort to reach the South Magnetic Pole barely failed by a scant margin of about fifty miles. The party turned back from 70° 36.5' S., 148° 10' E., where the dip was recorded at 89° 43.5', the Magnetic Pole being yet to the southeast.

The standardization of instruments by the Carnegie Magnetic Foundation, and the reduction and treatment of the observations by Dr. Bauer ensure more accurate and definite results than have been before attained. When such discussion appears it is certain that the present conflicting theories regarding the south magnetic pole will be satisfactorily harmonized.

Geology.—Although Antarctica is so covered by ice-caps as to confine geological researches to rare inland nunataks and infrequent stretches of ice-free coast cliffs, yet the general features of both King George and Queen Mary Lands were determined. Abundant red sandstones suggest that the Beacon sandstone formation, with dolerites, associated carbonaceous shales and coaly strata, extend from Adelie Land eastward to Ross sea region. On King George Land, Aurora nunatak, 1,100 feet high, disclosed "highly quartzose gneiss with black bands of schist." Horn Cliff, over 100 feet high had basaltic columns of dolerite 180 feet high.

The beacons were found to be part of a horizontal, stratified series of sandstones underlying

the igneous rock. Bands of coarse gravel . . . were interspersed with seams of carbonaceous shale and poor coal. . . . Several pieces of sandstone were marked by black, fossilized plant remains.

Near Penguin Point, 300 feet high, "the rock was coarse-grained granite, presenting great vertical faces."

In Queen Mary Land, Madigan nunatak, "the rock was of garnet gneiss, traversed by black dykes of pyroxene granulate;" Avalanche Rocks, 600 feet high, "rock mainly composed of mica schists and some granite;" Ross nunatak, "The rock was gneiss, rich in mica, feldspar and garnets;" Bar Smith nunatak rocks "were granites, gneiss and schists." Off the coast in dredging

Fragments of coal were once more found: an indication that coaly strata must be widely distributed in the Antarctic.

A meteorite was found on the main ice-cap.

Meteorology.—The dominant characteristic of the climate of Adelie Land were the blizzards, which give the title to Mawson's volumes. He says:

Such wind velocities as prevail at sea-level in Adelie Land are known in other parts of the world only at great elevations. The average wind velocities for our first year proved to be approximately fifty miles per hour.

Hourly records of one hundred miles were not very unusual, and gusts approximating 150 miles per hour were experienced. On May 15, 1912, the average velocity for the 24 hours was ninety miles. Later the reviewer hopes to comment on these remarkable meteorological conditions.

Biology.—Flora is practically non-existent in Antarctica, the brief list being mosses, lichens and algae. A growth of lichens on red sandstone is reproduced in color as "an example of the most conspicuous vegetation of Adelie Land." As might be expected, the most luxuriant growths were in penguin rookeries. On Gaussberg were "large quantities of moss." Most interesting were the tiny, eye-visible insects found, especially on Horn Bluff, where among the many patches of moss they were caught in myriads. Fresh-water lakes produced low forms of life, mainly microscopic.

Among these were diatoms, algae, protozoa, rotifera and bacteria.

Bird life was the striking feature of living nature; penguins, petrels, skuas and a new species of prion. Most interesting are the accounts of incubation, nesting, fishing, etc., of the various species. Eggs of practically every variety were obtained, including those of the silver-gray and antarctic petrels, previously unknown. The emperor penguin is the sovereign bird of Antarctica, and both eggs and rookeries are almost unknown. On Haswell Island, off Queen Mary Land, was found a large rookery of the emperors.

The Emperor penguins had their rookery on the floe, about a mile from the island. The birds covered four to five acres. . . . We estimated the numbers to be 7,500, the great majority being young birds.

Near by was found a large rookery, about 300 birds, of antarctic petrels nesting in gullies and clefts, laying their eggs on the shallow dirt, each having one egg. This island appeared to be a bird's paradise, as there were also large numbers of Cape pigeons, Southern Fulmars, Wilson petrels and snow petrels, while skuas also were present. Of 26 species of birds obtained 6 were penguins, 3 albatross and 7 petrels.

Seal life was abundant during the summer season, consisting of the seal elephant, sea-leopard, Weddell seal, crab-eater seal and the rare Ross seal, of which 6 specimens were obtained. The blue and killer whales were the only varieties observed. Space fails in which to dwell on interesting observations made of bird and of seal life, as well as to the rich and varied marine life procured both by shore-dredging and by deep-sea dredging at 11 stations in depths reaching 1,800 fathoms, and of tow-nettings down to 200 fathoms. The rich fauna and interesting flora of Macquarie Island will prove interesting to scientists. Among these the most important are the rookeries, the sea-elephants having some 500 cows in the largest, the king penguins about 6,000, and the royal penguins covering 26 acres of ground, approximately nearly half a million, as 150,000 birds are killed annually.

Glaciology.—The lands of Adelie, King George and Queen Mary are buried under thick glacial ice, through which protrude rare and small nunataks (ice-free peaks). Not only is the land thus covered, but the continental ice-caps project seaward along the entire coast-line to a greater or less extent. These projections, named by Ross *barriers*, and styled *shelves* by Mawson, are actually *oceanic* ice-caps. In King George Land Mertz and Ninnis glaciers push seaward indefinite distances, demarcation between land and ocean being undetermined, but each covers more than a thousand square miles of the Antarctic ocean. More remarkable is the Shackleton oceanic ice-cap which covers some 36,000 square miles of the ocean, its dimensions being 180 miles north and south by 200 miles east and west. Its surface extent is approximately equal to the combined areas of the states of New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut and New Jersey. Rising about 100 feet above the sea, its average thickness can not be less than 600 feet. Special interest attaches to the so-called ice-falls, where glaciers of very steep pitch impinge on the oceanic ice-caps, the Denman glacier being an example. Of this Dr. Wild says:

Denman glacier moving much more rapidly than the Shackleton Shelf, tore through the latter and shattered both its own sides and also a considerable area of the larger ice-sheet. At the actual point of contact was an enormous chasm over 1,000 feet wide, and from 300 to 400 feet deep, in the bottom of which crevasses appeared to go down forever. The sides were splintered and crumpled, towering above were titanic blocks of carven ice. The whole was the wildest, maddest, grandest thing imaginable. . . . Rending the Shackleton Shelf from top to bottom, it presses onward. Thus chaos, earthquake and ruin.

Other polar publications in recent years have been as sumptuously illustrated as are these beautiful volumes, but here is to be noticed a welcome restriction of personal photographic exploitation. The varied experiences of Mawson and of his subordinates, the wealth of sea-life and of bird-fauna, the immensity and peculiarity of glacial forms, have been wisely

utilized for several hundred illustrations which generally are of both popular and scientific interest. Of the 70 views of birds, seals and sea-elephants scarcely one could be spared. The bird-lover finds penguins and petrels of all ages and conditions; the sea-rover will delight in the scenes of seal and sea-elephant life; the meteorologist notes graphic records of winds and blizzards; the biologist sees prophetic shadows of the riches of later scientific publications; and the geologist finds pictured nunataks, columns of dolorite and cliffs of granite. The volumes will be welcome additions to scientific as to other libraries. The index is neither good nor full. Unfortunate was Sir Douglas in the "literary style" due to his associate, as shown in the foreword and by interjected poetry, which mar the dignity of the story of a great and historic expedition.

It is pleasing to find Sir Douglas Mawson in that restricted class that has a due sense of obligation to predecessors. After praising the skill and daring of Wilkes in the hazardous voyage of his squadron for 42 days along the borders of the antarctic circle, he adds:

It is wonderful how much was achieved. We may amply testify that Wilkes did more than open the field for future expeditions.

Americans thus owe a debt to Mawson, whose faith, courage and ability have given definite form to the 1,500 miles of the continent of Antarctica, which was reported by Wilkes only to be condemned and suppressed in narratives and on charts, and to be absolutely neglected by explorers for seventy years.

A. W. GREELY

The Lower Amazon. By ALGOT LANGE. New York, G. P. Putnam's Sons, 1914. 8°, ill., 460 pages.

Mr. Lange's new book shows a great advance over his earlier work entitled "In the Amazon Jungle" published in 1912. He has evidently learned the Portuguese language, a thing so many other travelers seem to regard as quite unnecessary, and he has apparently reached the wise conclusion that one does not need to go deep into the forests of the upper Amazon

in order to see and to learn interesting things. The experiences described by the author were confined mostly to a trip up the Tocantins, but without reaching the region of falls, another up the Mojú a short distance above the lower falls, and another to the Ilha do Pacoval in Lake Arary—all of them near Pará.

Personal experiences are related and illustrated by good photographs taken by the author, while the maps add greatly to the interest of the book. The author has a facile and attractive style, and no one has ever described more truly or more pathetically the poverty, sickness and despair that hang over the villages and rubber camps of the Amazon region.

In spite of the fact that he does not take kindly to the food of the country, the author is no longer a tenderfoot.

From a scientific point of view there is nothing new in the book. The ancient pottery from Marajó, on which he justly lays stress, has been known to the scientific world since 1870, when it was visited by Dr. Barnard, of Cornell University, and a paper on it was published by Hartt in the *American Naturalist* for July, 1871, while a much fuller account of it is given in the *Archivos do Museu Nacional* of Rio de Janeiro, Vol. VI., Rio, 1885.

Those who want to know how the conditions of life and of business in the Amazon Valley appear to one who is personally and freshly familiar with them will find much of interest in the final chapters regarding the conditions, prospects, food, health, and what the government is doing for the people. Those who believe in the boundless agricultural possibilities of the lowlands of the Amazon should read what is said at pages 27 and 387-8 of the great, enormously expensive, and tragic experiment of a North American firm on the Mojú, and the footnote about its final abandonment.

It is a relief to find a book necessarily containing many Portuguese words with so few typographic errors. On the other hand, it is not clear why the author always uses the Spanish word "machete" for forest-knife, or why he speaks of his men as "bucks." The long accent so often used by him on Portuguese words is not Portuguese at all: in the

cases observed it should be replaced by the acute accent. A few words are habitually misspelled, probably because they are not given in the smaller dictionaries: such as *cachassa* for *cachaça*, *meruhim* for *marui*, *tracachá* for *tracajá* (111), *chibêh* for *chibê* (115).

BOTANICAL NOTES

ANOTHER APPLIED BOTANY BOOK

WE have become so accustomed to looking for a new book, or a new revision of one of his earlier books by Professor Doctor Henry Kraemer, that it will not be a surprise to receive the announcement of another big volume of over eight hundred pages. In this book, which he calls "Applied and Economic Botany,"¹ he has in mind the needs of students in technical schools, and agricultural, pharmaceutical and medical colleges. At the same time the work will prove itself to be a valuable reference book for chemists and food analysts, while students in morphological and physiological botany will find much that is helpful in its pages.

In carrying out his plan for making the book useful for these various classes of persons the author wisely first makes a rapid survey of the plant kingdom from Schizophytes, Algae, Diatoms, Fungi and Lichens to Bryophytes, Pteridophytes, Gymnosperms and Angiosperms. With this preparation the student is next given a good course in elementary cytology and histology, bringing the text up to page 298, where one finds a chapter on the outer and inner morphology of higher plants. A short chapter on botanical nomenclature must be especially useful to the particular students for whom the book is designed, as it gives a few of the general laws of nomenclature, and follows these with twenty-nine pages in which over eight hundred botanical names are enumerated and their derivations briefly given.

The three remaining chapters are given to

the classification of angiosperms yielding economic products, the cultivation of medicinal plants, and microscopic technique, including reagents and their use. They all have a strong pharmaceutical bias, and yet the student in an agricultural college will find in them very much that will be helpful to him, more, probably, than in many of the books that have a more distinctly agricultural label.

It should be said that while there are many paragraphs and illustrations in this book that are identical with the author's fourth edition of his "Text-book of Botany and Pharmacognosy,"² published four years ago, this book is distinct from that, and appeals to a much wider circle of botanical students.

CYBELE COLUMBIANA

UNDER this title Dr. Edward L. Greene issues a 56-page pamphlet as No. 1, Vol. I., of a new botanical periodical which bears the date of December, 1914. Although it is known that the editor's address is Washington, D. C. (Smithsonian Institution), the publishers are given as Preston & Rounds, Providence; William Wesley & Son, London, and Oswald Weigel, Leipzig. Nor is there a statement of a subscription price, but it is stated on the title page that the price for this part is seventy-five cents, from which one may infer that the cost of the volume may be about three dollars. The same title page also informs us that this is to be "a series of studies in botany, chiefly North American," by the editor, "with occasional articles by others."

This first number opens with six pages of inimitable "explanatory," with reference to the title in which it is intimated that this is likely to be a violet periodical. This suggestion is borne out by the second paper on the "Violets of the District of Columbia, I." (pp. 7-33). Other papers are "Manipulus Malvacearum" (pp. 38-86) by the editor, and "Twelve Elementary Species of *Onagra*" (pp. 37-58, with 5 plates) by H. H. Bartlett.

Of course every systematic botanist will welcome *Cybele Columbiana*.

¹ Published by the author, 145 North Tenth St., Philadelphia, 1914. \$5.

² Lippincott, Philadelphia, 1910.

SHORT NOTES

MR. PAUL B. SEARS publishes an interesting account of the "Insect Galls of Cedar Point (Ohio) and Vicinity" in the December number of the *Ohio Naturalist*. It is accompanied by four plates in which every gall (68 in number) is figured.

DR. M. T. COOK's "Report of the Pathologist" of the New Jersey Agricultural Experiment Station, for the year 1913, contains a useful annotated list of the most common diseases of the year, arranged alphabetically by hosts. Apples and potatoes had the most diseases (13 and 12), with sweet potatoes following close with 9, and tomatoes with 7.

DR. G. H. SHULL continues to publish plant-breeding papers, as "Sex-limited Inheritance in *Lychnis dioica*,"³ and "A Peculiar Negative Correlation on *Oenothera Hybrids*."⁴

HERE may be favorably mentioned A. G. Vestal's "Prairie Vegetation of a Mountain-front area in Colorado"⁵ with eight good half-tones and a physiographic map of the region studied (near Boulder).

In the January number of the *American Naturalist* Professor E. C. Jeffrey publishes a vigorous criticism under the title "Some Fundamental Morphological Objections to the Mutation Theory of De Vries." The writer concludes that "hybridism is the best explanation yet put forward of the peculiar conduct of *Oenothera lamarckiana*, as well as other species of the genus in cultures." Apparently this is also the conclusion reached by Professor B. M. Davis in the same number of the *Naturalist* in his article "Professor De Vries on the Probable Origin of *Oenothera lamarckiana*."

Two new botanical journals, *Journal of Agricultural Research* and *American Journal of Botany* merit favorable notice here. The first is published by the United States De-

³ *Zeit. of inductive Abstam. u. Vererb.*, Bd. XII, Heft 5.

⁴ *Jour. of Genetics*, Vol. IV., No. 1.

⁵ *Bot. Gaz.*, Vol. LVIII., No. 5.

partment of Agriculture, and the second is the official publication of the Botanical Society of America. The first is by no means wholly botanical, and yet the articles dealing with plants, while tinged by some economic coloring, are of interest to the scientific botanist also. The second has taken high rank from the first in the literature of scientific botany. Its office of publication is the Brooklyn Botanic Garden.

It inspires hope to find that the "part" of the "North American Flora" which appeared December 31, 1914, is the first part of the final volume (34), but this hope of early completion is much dampened when we find that this part brings the total number of pages now printed up to about 2,000, which is only about one ninth of what the whole work will contain. It would not be fair, however, to estimate that since it has taken more than nine years to print this much (one ninth) it will require nine times as long, i. e., about one hundred years, to complete the Flora, for it must be remembered that authors have been at work on most of the volumes for the past ten years, and that we shall soon have a rapid appearance of successive parts. This particular part, which is principally from the hand of Dr. Rydberg, begins the tribe *Helenieae* of the family *Carduaceae*, and carries it into the tenth of the fourteen sub-tribes.

SPECIAL ARTICLES

A FOURTH MALLOPHAGAN SPECIES FROM THE HOATZIN

THE hoatzin is a curious, rather pheasant-like, South American bird, which is the only species in the strongly aberrant family *Opisthocomidae*, a family that is usually even ranked as a distinct avian order. This order or family, which is to say, this bird, has long been and still is a puzzle to the classifying ornithologists. Its genetic affinities are quite uncertain, although the approved general practice of the bird books is to put the family into a pigeon-hole next to that of the pheas-

ants or the pigeons, and close to that of the rails. But the hoatzin also shows certain affinities with the plantain-eaters (*Musophagidae*) and even, as Beebe points out, with the primitive lizard-tailed bird of the Upper Jurassic alates of Bavaria, the famous *Archæopteryx*.

In 1909 I had the welcome opportunity of examining a number of Mallophaga taken by Mr. C. William Beebe, curator of birds in the New York Zoological Park, from a hoatzin in Venezuela (its native land). I hoped these parasites might afford some clue to their strange host's genetic relationship, in that, if the Mallophaga proved to be kinds characteristic of pheasants, or, indeed, of any other group of birds, this fact might be advisedly taken into account by the systematic ornithologists. For it is quite certain that in many cases the host distribution of the Mallophagan parasites of birds is determined primarily by the genetic relationships of their hosts.

The Mallophaga of the hoatzin, representing three species of the parasites, did indeed prove to be characteristic—but, unfortunately, characteristic of the hoatzin! Two were new species, one a *Lipeurus* and one a *Colpocephalum*, belonging not at all to pheasant-infesting groups of *Lipeurus* or *Colpocephalum* species. Indeed the hoatzin's *Lipeurus* manifestly belongs to a group whose other members infest exclusively maritime birds, while the *Colpocephalum* also shows a likeness to two other species of the genus taken from maritime birds, although it is also rather like a third species described from a francolin (African partridge). The third species, a *Goniocotes*, is also recorded only from the hoatzin—Nitzsch found it on the bird fifty years ago—but it is of a genus which is otherwise almost restricted to pheasants. To this extent, and this only, did the parasites of the hoatzin as recorded by me in 1910¹ offer any suggestions as to the taxonomic position of the host.

I have recently had the opportunity of examining a fourth Mallophagan species from the

¹ *Zoologica*, Vol. I, pp. 117-21, Figs. 33 and 39.

hoatzin. In a collection of Mallophaga miscellaneously taken by Robert Cushman Murphy, of the Brooklyn Institute Museum, in recent years in various places, I find five specimens of a *Lamobothrium* recorded as taken from a hoatzin on the river Orinoco in Venezuela (date not given). Three of the specimens are immature, but two are adult and represent both sexes.

The extraordinary thing about this *Lamobothrium* of the hoatzin is that, although it has been described by Cummings (Bull. Ent. Research, Vol. IV., p. 43, 1913) of the British Museum as a new species it is certainly very closely related to an already known species described under the name *L. setigerum* by Piaget in 1889 from the Cayenne ibis (*Ibis cayennensis*) which is a native of the same general geographic region to which the hoatzin is confined, namely, South America from the Amazon northward. Indeed, my own judgment is that the hoatzin's parasite should rather be called a variety of this species than the representative of a new one. *Lamobothrium setigerum* is a striking Mallophagan species, well-characterized by a group of curious, heavy, flattened and broad, short, spine-like hairs projecting forward from the clypeal margin, and it is certainly a parasite of ibises and cranes, for I have recently described two other varieties of the species from other ibises. One of these varieties, *L. setigerum* var. *africanum*, came from *Theristicus hagedash* from the Kilimandjaro region of East Africa (collected by Sjöstedt's Swedish Expedition to Kilimandjaro-Meru), and also from the same host taken near Mfongosi in Zululand by a collector for the Durban (Natal) Museum. The other variety, *L. setigerum* var. *cubensis*, came from a courlan (*Aramus gigantus holostictus*), from Cuba, collected by Mr. C. D. Ramsden.

It is interesting enough to find a single striking Mallophagan at home on a Cayenne ibis of South America, a wood ibis of East Africa and a courlan of Cuba, but the interest becomes excessive when a closely allied species is found on the hoatzin in Venezuela. Is the hoatzin, after all, less of a pheasant or

a pigeon and more of a water bird than commonly held? It does indeed, as observers have repeatedly pointed out, have a habitat and habits not unlike those of such water-liking birds as ibises and rails. It inhabits trees and undergrowth along rivers and in marshy regions. It makes nests usually in trees over water. The nests are also, says Beebe, the most recent and most careful observer of the habits of the strange birds, hardly distinguishable from those of the guinea herons, and built in the same situations. But all this may, of course, mean nothing as to the bird's phylogeny.

The suggestion that may come from some that my specimens of *Lamobothrium* from the boatzin may have come to this host from some Venezuelan ibis or heron host by natural straggling is extremely unlikely for Mallophagan individuals of different bird species. This is only recorded, and practically only possible, among individuals infesting two bird sorts that consort gregariously in considerable numbers and closely. This is not true of the boatzin, as Beebe's observations make clearly evident. Mallophaga are in only rare instances, outside perhaps of crowded hen-houses and chicken yards, colonies of chimney swifts or swallows, and places of common roosting or other foregathering of many bird individuals of a kind, found *alive* (or even dead) off the body of a bird. They make their migration from host individual to individual on occasions of actual bodily contact of these hosts, as at mating, and in the nest.

So it is practically certain that the boatzin is host to a Mallophagan kind, which is most nearly related to a species, or, perhaps indeed, is but a variety of the very species, found heretofore only on Old and New World ibises and courlans.

VERNON L. KELLOGG

STANFORD UNIVERSITY

THE TOXICITY OF INSECTICIDES

CERTAIN facts which may be of general importance in physiological investigations were brought to light in a study of the toxicity of

insecticides now under way at the California Agricultural Experiment Station.

A very elaborate series of determinations were made on the effect of hydrocyanic-acid gas on scale insect eggs. The plan of the experiment was to separate the eggs found beneath a scale insect into two lots of about equal size, placing them in gelatin capsules, one lot being allowed to hatch without treatment, and the other after being exposed to the gas for a definite time. The species studied lay on the average rather more than a thousand eggs, and each series of experiments included the eggs from a hundred insects. Nearly three hundred series were thus studied, including five different species of scale insects from eleven different localities in California.

Solutions of hydrocyanic acid of varying concentration were placed in closed glass containers and the open capsules containing eggs to be treated were suspended above these solutions. The density of the gas above these solutions is dependent on the concentration and temperature.

After hatching, the capsule was placed under a microscope and an estimate was made of the hatch in each lot, using only the numbers 05, 10, 20, 30, 40, 50, 60, 70, 80, 90, 95, 100 per cent. The following table will show the results of one series.

The upper right-hand corner gives the results with the weakest dose and shortest time. As would be expected, in the opposite corner, there is no hatch and the mean percentages given below show the effects of the different concentrations, the last two or three of which are completely ineffectual since the hatch is the same as the untreated check lots.

The series of means given at the right bring out an entirely unexpected result, apparently showing that the length of time the eggs remained exposed to the gas has very little effect. This is, however, not at all the fact as shown by the curves on the left side of the table.

The average means of 72 series of experiments with the same insect from the same food plant and locality are 58.31, 59.20, 56.10,

54.30, 52.20, 50.10, 48.50, 48.01, 46.51 and 43.30, respectively.

In all such experiments individual variation will be very pronounced, but averages based on as large a number of series as this are quite dependable, and we can safely say that long continued action of cyanide at a strength below that producing fatal results exerts on the contrary a benign influence.

It will be remembered that fatal results follow, as a rule, from weaker doses when the time of exposure is long, but far short of the theoretical proportion that would follow on the assumption that the toxicity was dependent on the amount of gas absorbed and that this varied directly as the time and density.

The possible explanation used on the assumption of the production of antibodies within the egg can only partially, if at all, account for the facts since another phenomenon, the acceleration of the rate of development resulting in an earlier hatching, is also evident.

The quickened cell activities indicate that the effect of cyanide, at least in light doses, is to increase cell permeability, a process of rejuvenescence which may be specially useful in an insect's egg so full of yolk material. Decreased permeability is generally considered the measure of approaching death, but it may be that acute poisons like the strong in-

secticides produce a violent death of cells by the sudden or excessive increase in catabolism.

A third suggestion which may seem rather bold to offer in the case of animal tissue is the possibility of the nitrogen of hydrocyanic acid being available as food directly utilizable by the protoplasm of the cells. The basis for this suggestion is the fact that in a series of experiments by Mr. E. Ralph Ong, conducted in my laboratory with seeds in hydrocyanic acid solutions, a very remarkable and similar acceleration in time of sprouting was observable when the solution was slightly short of a toxic strength, and these plants developed with all the appearance of having had a strong nitrogen fertilization. There is no doubt of the ability of plant tissue to utilize nitrogen in various forms, and we know of no special mechanism necessary to accomplish this which is characteristic of vegetable protoplasm.

The cyanide produced from hydrocyanic acid absorbed in the tissue of a scale-insect egg when not immediately fatal, but present in considerable quantities may be either utilized as food or act as a disturber of the equilibrium of cell permeability or both and in addition it may cause a reaction bringing about the production of antibodies which will neutralize the poison. One or more of these factors may produce a degree of immunity from

the effects of long continued exposure to hydrocyanic-acid gas and, indeed, counteract the effect to such an extent that the surviving eggs hatch better than those with short treatment in the gas. Both animal and plant tissues thus exhibit very decided evidences of definite cyanide stimulation.

C. W. WOODWORTH

UNIVERSITY OF CALIFORNIA

THE AMERICAN SOCIETY OF NATURALISTS

THE thirty-second annual meeting of the American Society of Naturalists was held in the zoological laboratory of the University of Pennsylvania on December 31, 1914. In affiliation with the society this year were the American Society of Zoologists, the Botanical Society of America, the Society of American Bacteriologists, and the American Psychological Association.

By-law No. 3 of the society was amended to read "The Records of the society shall be published once every three years beginning in 1914. The Records shall contain the constitution and by-laws of the society, the minutes of all meetings held within the period covered, the treasurer's reports, and a full list of members of the society."

An invitation to the society from the Pacific Coast Committee on Zoological Program to participate in the sessions concerned with zoology during the convocation week of the American Association for the Advancement of Science, to be held in August, 1915, received the following action. It was voted that the secretary express the appreciation of the society for the invitation and its best wishes for the success of the Pacific Coast meetings. The American Society of Naturalists suggests that members resident on the Pacific Coast organize, if they so desire, a section of the society in accordance with the provisions of Art. IV., Sec. 3, of the constitution, and that this section in cooperation with the American Association for the Advancement of Science hold a meeting in August, 1915.

There were elected to honorary membership in the society Hugo De Vries and Wilhelm Roux.

The following were elected to membership: W. C. Allee, University of Oklahoma; Charles E. Allen, University of Wisconsin; Cora J. Beckwith, Vassar College; Charles E. Bessey, University of Nebraska; William W. Browne, College of the City of New York; W. A. Cannon, Desert Botanical Laboratory; Ralph V. Chamberlain, Museum of Comparative Zoology; Maynie R. Curtis, Maine

Agricultural Experiment Station; John A. Detlefsen, University of Illinois; Dayton J. Edwards, College of the City of New York; Arthur H. Estabrook, Eugenics Record Office; Richard Goldschmidt, Kaiser Wilhelm Institut für Biologie; John W. Harshberger, University of Pennsylvania; Marshall A. Howe, New York Botanical Garden; Hartley H. T. Jackson, U. S. Department of Agriculture; Thomas H. Kearney, U. S. Department of Agriculture; Henry H. Lane, University of Oklahoma; W. H. Longley, Goucher College; Henry Laurens, Yale University; George R. Lyman, U. S. Department of Agriculture; John M. Macfarlane, University of Pennsylvania; Frederick C. Newcombe, University of Michigan; Susan P. Nichols, Oberlin College; Theophilus S. Painter, Yale University; Arthur S. Pearse, University of Wisconsin; Herbert W. Rand, Harvard University; Charles G. Rogers, Oberlin College; Forrest Shreve, Desert Botanical Laboratory; William C. Stevens, University of Kansas; L. B. Walton, Kenyon College; Orland E. White, Brooklyn Botanic Garden.

A cordial vote of thanks was passed to the University of Pennsylvania for its hospitality.

The program of the morning session was as follows:

A. F. Blakeslee and D. E. Warner, "Correlation between Egg-laying Activity and Yellow Pigment in the Domestic Fowl."

A. F. Blakeslee, "A Sexual Mutation in a Vegetatively Propagated Pure Line of Mucors."

Sewall Wright (by invitation), "The Albino Series of Allelomorphs in Guinea-pigs."

H. S. Jennings, C. S. Lashley, A. R. Middleton, F. M. Root and Ruth J. Stocking, "Researches on the Inheritance and the Results of Selection in Uniparental Reproduction."

Edward M. East, "The Phenomenon of Self Sterility." (Read by title.)

Helen D. King, "The Effects of Inbreeding and Selection on the Growth, Fertility and Sex Ratio of the Albino Rat."

H. H. Newman (by invitation), "Development and Heredity in Heterogenic Teleost Hybrids." (Read by title.)

Alice M. Boring, "Data on the Relation between Primary and Secondary Sexual Characters in the Domestic Fowl."

R. A. Emerson, "Somatic Mutations in Variegated Maize Pericarp."

H. J. Webber and C. H. Myers, "Bud Variation within Tuber Lines of the Common Potato."

Clarence C. Little, "The Inheritance of Certain Types of Spotting in Mice."

George G. Scott, "Some Indications of the Evolution of the Osmotic Pressure of the Blood and Other Body Fluids." (Read by title.)

H. D. Fish, "The Increase in Homozygosis which results from Certain Systems of Inbreeding."

The session of the afternoon consisted of a symposium, in joint session with the American Society of Zoology and Section F of the American Association for the Advancement of Science, on the subject "The Value of Zoology to Humanity."

E. G. Conklin, "The Cultural Value of Zoology."

C. B. Davenport, "The Value of Scientific Genealogy."

G. H. Parker, "The Eugenics Movement as a Public Service."

Stuart Paton, "Preparedness for Peace."

H. F. Osborn, "The Museum in the Public Service."

The Naturalists' dinner was held on the evening of December 31, at the Hotel Walton, with one hundred and forty in attendance. The president, Professor Samuel F. Clarke, described the founding and early history of the society, following whom Dr. A. G. Mayer, as retiring vice-president of Section F, gave an illustrated address on "The Research Work of the Tortugas Laboratory of the Carnegie Institution of Washington."

The officers of the Society for 1915 are:

President—Frank R. Lillie, University of Chicago.

Vice-president—Rollin A. Emerson, Cornell University.

Secretary—Bradley M. Davis, University of Pennsylvania (1914-16).

Treasurer—J. Arthur Harris, Carnegie Station for Experimental Evolution (1915-17).

Additional Members of the Executive Committee—Ross G. Harrison, Yale University (1914-1915); Raymond Pearl, Maine Agricultural Experiment Station (1914-16); Henry V. Wilson, Adeline Ames, Department of Agriculture, University of North Carolina (1915-17).

BRADLEY M. DAVIS,
Secretary for 1914

AMERICAN SOCIETY FOR EXPERIMENTAL PATHOLOGY

First session Monday, 2 P.M., December 28, 1914. The society was called to order by Presi-

dent R. M. Pearce. Report of council by secretary. The following papers were presented by members of the society:

"Studies on Streptococci," by E. C. Rosenow. Discussion by Drs. Pearce, Wells, Adami and Whipple.

"Observations on the Formation of Antibodies," by Ludwig Hektoen. Discussion by Dr. Karsner.

"Auto-plastic and Homio-plastic Transplantations of Tissues," by Dr. Leo Loeb. Discussion by Drs. Opie, Ulenhuth and Loeb.

"Further Studies in Nitrogen Retention and Renal Function," by Dr. H. T. Karsner. Discussion by Drs. Wells, Pearce, Opie and Karsner.

"Metastatic Calcification," by Dr. H. G. Wells. Discussion by Dr. Adami.

"Studies in Bile Pigment Excretion," by Drs. G. H. Whipple and C. W. Hooper. Discussion by Drs. Wells, Pearce and Whipple.

"The Influence of Diet upon the Progress of Bacterial Infection," by Drs. E. L. Opie, L. B. Alford. Discussion by Drs. Loeb and Wells, Karsner, Whipple and Opie.

Papers read by title:

"The Effect of Previous Intravenous Injections of the Pneumococcus upon Experimental Pneumonia by Intrabronchial Insufflation of the same Organism," by Drs. B. S. Kline and S. J. Meltzer.

"Further Studies Upon the Experimental Production of Leprosy in the Lower Animals," by Dr. C. W. Duval.

At the conclusion of this scientific session the society went into executive session for the election of officers and new members and transaction of business. Dr. Theobald Smith was unanimously elected president for the ensuing year. Dr. G. H. Whipple was elected vice-president for the ensuing year. Dr. Peyton Rous was elected secretary-treasurer for the ensuing year. Dr. R. M. Pearce was elected councillor in place of Dr. Harvey Cushing whose term expired.

The following new members were elected: Dr. James B. Murphy, of the Rockefeller Institute, Dr. L. G. Rowntree, of the Johns Hopkins Hospital, Dr. Richard Strong, of the Harvard Medical School, and Dr. M. C. Winternitz, of the Johns Hopkins Medical School.

On Tuesday afternoon, December 29, at 2 P.M., and Wednesday morning, January 30, 9 A.M., joint meetings of the Physiological, Biochemical, Pharmacological and Pathological Societies were held. The details of these meetings may be found in the proceedings of these respective societies.

THE FUNCTION AND TEST OF DEFINITION AND METHOD IN PSYCHOLOGY¹

AMID all of the discussion current in the last few years among psychologists the unprejudiced outside observer might think that we were a body of men professing to develop and teach a science who did not know what that science was to deal with and without any idea or with too many ideas as to the methods that should be followed in undertaking to develop our knowledge of the unknown or undetermined subject-matter. Psychology is at once the science of mind, the science of consciousness, the science of experience, the science of behavior. Psychology must be studied only by careful watching of the processes of the individual, by the individual himself; one who does not proceed in this way is no psychologist, no matter how valuable his work may be as physiology or biology or sociology. On the other hand, we are assured by just as devoted and well-recognized psychologists that psychology must deal only with the responses of the individual, with what can be seen from the outside, and that what the first man deals with really has no existence, or at best is entirely irrelevant to the responses, to anything that is of scientific interest. If we are to be taken at our own valuation we are either altogether unfit to carry on the task we have set ourselves or entirely unprepared for it.

As a matter of fact I presume this comes from the youth of the science, at least from taking a definition and formal statements

¹ Address of the Vice-president and Chairman of Section H—Anthropology and Psychology, Philadelphia, December 30, 1914.

MSS. intended for publication and books, etc., intended for review should be sent to Professor J. McKen Cattell, Garrison-on-Hudson, N. Y.

of method too seriously. Other sciences have the same trouble with definitions. It would be as difficult to find a single phrase that would mark off physics from chemistry in an absolutely accurate and adequate way as to distinguish psychology from anthropology or human physiology, and quite as difficult to formulate a definition of either chemistry or physics that would satisfy every one, as to define psychology. From most traditional definitions, J. J. Thomson as physicist has no right to be discussing atoms, and similar violations of the sacred rights of physics as defined in the text-books might be cited on the part of men who are generally labeled as chemists. These men, and the better men in the sciences in general, are not interested in phrasing definitions but in solving the problems that their science, or closely related sciences present to them. On our side, much of the discussion, or the liveliness of the discussion, comes from the fact that we assume that the definition must determine the science rather than the science the definition. It is assumed, tacitly, to be sure, that a definition is logically prior to the science, is a statement from which the science may be deduced or a program that the science is to follow in its development rather than a mere statement of what the science has done, or a formulation, as best we may, of the aims common to the mass of workers who are generally accepted as psychologists.

If we are to accept the view that a definition is the servant of our science rather than its master, if we are to say with Judd "that we all know what psychology is," then the test of a definition is that it shall state the aims of the science in the briefest form possible, and in terms that shall be best understood by the individuals for whom it is intended, that shall be least open to misunderstanding. If we consider

the traditional definitions we find that each is open to certain objections when tested by these criteria. The traditional science of mind implies a general agreement as to what mind is, and this is lacking. It also suffers from the implication to men who do not know what psychology is that we are to deal with an entity of some sort, for all terms after they become familiar come to be regarded as denoting things. When mind is defined in a way to avoid this implication, as it usually is in the succeeding sentence, it is no longer recognizable by the uninstructed. The same objections hold against consciousness; it was at first innocent enough of mystical significance, but a very few years of use to designate the material to be studied set it up as a thing or inner force. Hypostatization followed close upon the heels of its entrance into definitions. If psychologists were to study it as the material of their science it must be the equivalent of mind as mind is of soul, it must then be an active agent that psychologists can see, although, like the holy grail, sight of it is granted only to the pure in heart. Experience as a substitute for consciousness or mind escapes some of the disadvantages in that it is less likely to be personified or substantialized, but it is difficult accurately to separate the part of experience that psychology is to treat from that touched upon by the other sciences. When this is accomplished it affords little advantage over mind or consciousness.

In view of all these circumstances a change from the inside to the outside, to describe the object of psychology as behavior, offers the most advantages. Behavior is at once simple enough to require the minimum of definition and is hardly capable of being transformed in meaning to designate a thing or force. It takes, too, the attitude toward the mental of the average non-reflective individual. The ordinary

man is interested primarily in the mind of others rather than in his own. He is interested in furnishing stimuli of various sorts to other men that shall lead or compel them to act in certain ways rather than in how he himself or his fellow feels as he acts. The advertiser is content if his copy induces men to buy, the orator if his discourse brings him votes or changes the mind of his audience to his own opinion. The salesman is content with his knowledge of practical psychology if his patter leads the buyer to part with his money, the general or statesman if he can divine how his opponent is likely to act under the conditions he presents to him. In the simplest as in the most complex and important affairs of life the practical man is concerned not with mental states, but with behavior. He usually assumes mental states to account for behavior, but they are purely hypothetical, not the result of introspection, however crude. Good temper and bad temper, conceit and modesty, weak will and strong will, are all names for qualities that can be recognized through behavior alone, or at least can be no more easily recognized through introspection than by observation. The bad-tempered man is as little aware of it and can give as little explanation for it as his friends or enemies. He knows of his weakness only by observation of his actions rather than by any mental process that precedes or accompanies his acts, and is probably, through his prejudices, even less likely to recognize the quality than are others. To turn in upon one's self, to have "too much contemplation in one's eye," is for the average man a sign of weakness, a forerunner of mental disintegration. The mental states of the uninitiated are not known through watching himself, but assumed to explain the behavior of another man.

On the theoretical side, behavior has the

advantage over the more subjective terms as a designation of the subject-matter of psychology that it includes many processes that are treated by practically all of us. Very much of the active life bears very little ascertainable relation to consciousness when closely analyzed. It is not putting the matter too strongly to say that the more the voluntary processes are analyzed, the smaller part does consciousness seem to play in them. The less voluntary processes, habit, instinct and the various impulses are also included in the list of psychological processes, although little or no consciousness accompanies them. They are quite as easily predicted from without as from within. Even the learning processes and the recognition processes are studied quite as easily by observation as by introspection. One knows that one recognizes through observation of his mental states, but sees very little of how he recognizes. One can be almost as sure that another has recognized him as he can that he has recognized the other. Neither can determine immediately how the recognition has taken place. Thinking by the most recent workers would be put on much the same level. Even the self or personality, if one is to use the more familiar and objective term is quite as much removed from introspection as from observation. On the whole, if one were compelled to choose between behavior and consciousness as a designation of the subject-matter of psychology and then should apply the term in all logical strictness, it would be found that more of the actual content of the average text-book on human psychology would need to be eliminated if one deleted the portions that applied to consciousness than if one omitted those sections that were devoted to behavior.

If we leave human psychology and turn to animal psychology, no one would deny

that a study of behavior is all that we have aside from an uncertain amount of discussion as to how closely or remotely the human mind can find a parallel behind the actions of the lower forms. Similar is the problem raised by the assertions of the recently prominent group of philosophers who insist that consciousness is non-existent—at the most an illusion. For them psychology as the science of consciousness has ceased to exist. While fashions in philosophy change too often for the psychologist to attempt to square his definitions with all of them, it is nevertheless interesting to see that psychology defined as behavior is quite as applicable to the philosopher without a mind as to the rest of intelligent creation. His responses to stimulation, his perceptions as they modify his actions, his memory and capacity for reasoning with varying degrees of accuracy under different conditions, even the conditions that led to his denying that he was conscious, could be studied with some degree of satisfaction. Antecedent acts and experience could be shown to give rise to the various actions, and would go far toward explaining them.

But it does not follow that because much of the material in the text-books and much that the common mind regards as mental is really a matter of behavior that a definition of psychology as the science of behavior would change the nature of the science. As was asserted in the beginning, the science makes the definition, not definition the science. There is no mental process, however strictly one may follow the subjectivist, that does not have some influence upon behavior. The very description of them in words itself implies behavior. Perception in all forms, images of all types, feelings and emotions, not to mention the mental antecedents of voluntary action, all play a part in determining the character of the individual. Each modifies his be-

havior. If one understood thoroughly the behavior of any man he would also understand his consciousness. It is possible to neglect behavior in the study of consciousness, but not to neglect consciousness in the study of behavior. The only ones who could object to the statement that behavior was to be understood in terms of consciousness are the men who deny the existence of consciousness, and they need no convincing as to the possibility or even the desirability of defining psychology as the science of behavior. To my mind, the adoption of behavior to designate the subject-matter of psychology need not change in the least the treatment of the subject as ordinarily presented. Even the individual who finds no interest in anything but the classification of his own mental states, if such there be, could go on with his classification, and, if he classified all of his states, would find an awareness of his own movements among them, and find these very important both as the beginning and the end of his series. He would probably prefer another description, but his own work would be included in the definition, he would still be within the pale. By adopting the definition we change our description of the science not the science itself.

It should be added that in the nature of the case no definition can be satisfactory. No single phrase, or paragraph even, is sufficient to definitely delimit the subject-matter of psychology. Even a short text can not include and describe all that might be and is in reality included in the science. The meanings of terms are bound to grow, and with each change a definition becomes inaccurate. Of course, were one to take the other attitude that the definition fixes the science, the difficulty would be avoided. But there is no absolute authority to fix that definition and even if it could be fixed by such an authority the science would soon

find itself on a procrustean bed. Advance would be impossible. If the science is to determine the definition, the statement can be at best a short-hand description of it, it can do no more than approximate either completeness or accuracy. A definition is no more than a choice of evils. All that is incumbent upon us is that of all evils we choose the least.

Even more the subject of conflict at the present moment than the definition of the science is the question of the methods that may be employed in developing it. On this point psychologists have been even more divided and each more strenuous in insisting upon his own attitudes. Whether a new science attracts the more aggressive and in consequence more intolerant men in the scientific community, or the very uncertainty of the subject of method leads to an over-emphasis of assurance, a whistling to keep up courage, or what the psychoanalyst would call an emotion that arises from the constant repression of a complex of doubt that must be kept below the threshold because of its unpleasantness, it is undoubtedly true that psychologists have spent more time than most scientists in insisting upon their own method or the methods that they have adopted. *Ex cathedra* statements, and assertions that all who do not follow their own method are not psychologists and that all who do follow it and reach results that do not conform with their own are not psychologists, have been relatively very frequent. Several instances may be mentioned. Wundt, as you all know, early in the history of the science asserted that no man who could not obtain the sensory and motor differences in reaction times was to be included among psychologists, and only recently after a controversy with Bühler on the *Ausfrage* method he announced that he would read no more reports on work done by that

method. At present Müller and Meumann, both respected leaders in the science, are indulging in a controversy in which each seems to fall back upon similar personal criteria as a justification for their impatience with the standpoint of the other. No psychology without introspection has been a motto frequently implied if not explicitly asserted, and, ironically enough, an advocate of the newest method to claim a monopoly turns upon the former tyrant among methods with the assertion that it has been dealing with an illusory material, that the method is worthless, and that its followers have retarded the development of the science and are in general cumberers of the earth. Turn about is fair play, but to meet intolerance with intolerance is usually more interesting and picturesque than helpful to the science.

To my mind the great difficulty on both sides lies in the same tendency that makes trouble with the definition, the method rather than the science is given priority. The method should be the servant of the science, not the science the slave of the method. The only test of a method is its accomplishment. Just as with definition no authority exists that can once and for all say this is the method, follow it or cease to be a psychologist. Attempts on the part of any one to take that tack are quite certain to be a means of covering the uncertainties or the mistakes of the author; they are certain not to be fruitful for the science. These must have their origin in prejudice rather than in any universal law revealed to that individual alone. Any method that gives results must be kept, and the more we have the better. What are to be called results offers room for difference of opinion, but the gradually developed judgment of the recognized members of the science and of related sciences will be the final arbiter of that question. With

the complexity of our subject-matter any method that can give a point of attack is to be encouraged on general principles. The methods that prove fruitless will disappear soon, the valuable ones will assert themselves. Meanwhile a broad hospitality that will encourage originality, rather than a hidebound insistence upon any single method, will certainly be beneficial for the advancement of the science.

That the advocates of a method are prone to exalt the method at the expense of the science, to make over the science if not the man to conform to the needs of their method, can be seen to-day in the writings of both introspectionists and behaviorists. The introspectionists in general desire to put all the essential mental operations on the inside, to find them in images, while Watson, their newest and most vigorous opponent, would put all on the outside. Thus in the thought processes the more thoroughgoing believers in images insist that thinking that does not go on in images is not thinking, or that the individuals who announce that they do not use images have overlooked their images through faulty observation of some sort. They themselves heap up images for each of the reasoning operations, in spite of the fact that many of the processes they mention are obviously individual if not irrelevant to the end that is accomplished. Watson, similarly, after announcing that psychology is a branch of behaviorism and its method is the observation of external responses under experimental conditions, feels himself compelled to transfer the thinking process in its entirety to the outside where the experimenter can discover all that goes on. Thinking must be found in contractions of the larynx, in slight movements of the larynx, or in other movements at present undiscovered which must however lie upon the surface of the body. It is not apparent why he

should insist on the slight movements of the larynx, for which delicate apparatus should be used, rather than upon the full movements of speech which may be even more completely analyzed by the ear. If the language of the individual does not tell us why he reaches certain conclusions when he thinks aloud, I can not see how the slight movements made when he thinks to himself are to be of any greater aid. So far as any evidence on the subject exists, the movements in thinking are but faint replicas of the movements of ordinary speech.

If we take the thinking process as an instance, I am inclined to believe that the great difficulty is not so much with the method as with the way in which it is applied. Advocates of both tend to deal too much with irrelevant materials. As an impartial onlooker I am convinced that much of the imagery that we hear so much of in the long introspective accounts is wholly or largely irrelevant to the problems, and I am sure if I may indulge for a moment in the cocksureness that I am criticizing, that the slight recorded movements that are mentioned on the other side would be at most irrelevant accompaniments, rather than essential conditions of the thought process. If one observe any bit of thinking as revealed in the speech of another or in one's own consciousness, if one happen to have a consciousness, it is seen that there is no difficulty in knowing that a conclusion has been reached and in deciding that it is or is not adequate. How the conclusion is reached, and why it seems adequate or inadequate, is revealed neither to introspection nor to observation. To answer either of these questions one must proceed as one would in the natural sciences by varying the antecedents of each process until one discovers that certain are the real causes and others are chance accompaniments. If experimentation is not

possible, study of the conditions under which the conclusions are reached and of the way the conclusion varies with the immediately preceding events and with earlier experience may give the same result. Heaping up descriptions of accompanying imagery or of accompanying movements may be of no more value to this end than is collecting postage stamps in the study of the causes of events in the world's history. Both may be interesting as mementoes, but throw no light upon underlying causes.

In the list of irrelevancies in connection with the reasoning processes is the question whether one may think without images so much under discussion at the present. Proof that men may think without images is a valuable advance, not in itself, but in so far as it raises the question how he really does think. If two men reach the same conclusion, one with, the other without images, obviously the presence or absence of imagery is equally unessential. The only alternative is to believe that the one man has images, but does not notice them, or that the other thinks in spite of his images. That one thinks and how is the essential, and the individual with the imagery is no more and no less effective in attaining conclusions than the one without. They are equally accurate, and neither knows directly how he accomplishes his results. The quarrel over the nature of the mental state has obscured the more important problems of reasoning. For this reason it seems to me that the important accomplishment of the Würzburg school has been not to prove that thinking may go on without images, although I am prepared to accept that, too, but to show that the antecedent purpose, the *Aufgabe*, determines the course of thought. One shows what is not needed, the other an element that is essential.

From this standpoint the attempt to set up a new element of pure thought rather than to study the actual operations of thinking is unfortunate. All that has been shown by introspection is that images are lacking, not that anything else is present. To assume pure thought is to hypostatize our ignorance. Particularly objectionable is this because no attempts have been made to determine its conditions, to set limits to it, or to reduce it to any law. It is merely another addition to our collection of postage stamps, perhaps even less valuable than the others because denomination and name of the country have been worn off, and no one knows what the remnants of the portrait mean. The great disadvantage with the introduction of the term, is that, as with all names, in the course of a few years all problems of thought, all reasoning operations, will be explained by reference to it. If one asks why John reasons better than Jane the answer will be that John possesses more of the pure thought element. To be sure, none of the advocates of the new school mean anything of the kind at present, and it may never develop in this way, but the tendency to use these more or less mystic entities in mystic ways is strong. A word becomes a thing on the slightest provocation.

By asserting that conscious states may be irrelevant, it is not implied that they are always or even usually irrelevant; in fact, in opposition to Watson it seems to me that many mental states are relevant and that one knows what goes on in mind quite as well or better from the inside than from the outside. Not only does the study of imagery indicate its existence in all but relatively few individuals, but Meumann's and many other studies indicate that it has an important influence upon the method and capacity of an individual's learning, his spelling, the methods of mental calculation and many other activities. To take

a concrete instance, if I may be indulged for a mention of names: Here are Yerkes and Watson who have been working approximately the same time with the same problems and materials and attaining the same conclusions in their chosen field. But recently, when they came to the application of methods to human psychology, one makes much of imagery and of introspection in general, as much as the most ardent introspectionist could wish, while the other denies the existence of imagery except for the sake of argument in a few sporadic cases. If one assume the attitude of the average man and argue from behavior to consciousness, it is evident that while Yerkes has a large amount of concrete imagery, probably dominantly visual, Watson has relatively little concrete imagery, and what he has is of the motor type. An assumption of this sort on the basis of behavior alone, if we are to include writing psychological treatises under behavior, is of course not to be compared in value with a few minutes' introspection, but may be ventured as a guess. If this holds, not only is consciousness and even imagery an essential determinant of behavior, but it is possible to show that one important bit of the behavior of the man who would most emphatically deny the existence of imagery is due to imagery or its lack. To ascertain that one does not have imagery is just as much a contribution of introspection as to determine that it exists. To give over introspection altogether is to abandon the method that has given much if not most of the body of knowledge that we have at present and to insist that we use only a method that so far has been little tried, and which, in the form that is suggested, the inference of mental states from slight movements, has when tested proved relatively futile.

If one broaden slightly the term con-

sciousness and the implication of introspection it seems possible to put the problem of psychology in a form that removes all ground for complaint on all sides. This is to include in consciousness and among ideas the fundamental states upon which all effective mental life depends. More immediate than the image, more certainly made out than any slight movement, is the series of assurances that we have that certain events, subjective or objective, take place. We know that we recall, we are sure that we recognize, believe, see objects, that we are pleased, desire certain things, and are on the point of striving for them. These assurances are common to the man who has images and to the man who has none, to the man who believes that mental life is fundamentally sensory and to him who regards it as altogether motor, to the realist and to the idealist. They might be called mental states, or mental functions, had not both been spoiled by use. It is the mind of the practical man before he does any theorizing. It is likewise the starting point of the psychologist. He begins to deal with images and with slight movements only when he becomes sophisticated, and when he becomes sophisticated he forgets his starting point and substitutes his explanation of consciousness in terms of images, movements, or pure thought for the fundamental reality. In time he assumes that the explanation instead of the fact is the reality, just as the naive man assumes that memory, attention, will and self are immediately known realities.

My plea is that the real subject-matter of psychology is the fact that we attain conclusions, that we perceive distance, that we are prepared to act, rather than the imagery, or the movements that accompany, precede or succeed. This group of facts common to all schools may be explained in different ways or need not be explained at

all. It is always possible to determine the laws of any mental operation, as has been done by the experiments on memory, by the statistical method applied to everything from heredity to advertising by the Cattell school and others, by the investigators in education, in medicine, in the studies in efficiency, and also in the early experiments on Weber's law and reaction times. Whether classed as conscious processes or as behavior, every one is capable of deciding whether a sound is more intense than the preceding, whether a picture is more or less beautiful than another, of recalling and recording the words that were spoken in a conversation a month ago (whether truly or not is for the experimenter to decide) of pressing a key when a stimulus is given. That is all that these experiments require. How these processes are carried out is entirely indifferent. Granting that they may be carried out, a science of psychology is possible. All disagreement between schools is as to how these judgments are made, that they are made all agree.

This conclusion does not mean that psychology need stop here. How one remembers, the mental antecedents of an act and all questions of classification and of ultimate explanation are bound to be raised and are at once valuable and interesting—my only contention is that the nature of the explanation offered makes no difference to the fact to be explained, a statement that is obvious enough but which seems to be lost sight of in much of the controversy that is raging. The laws that I have been mentioning correspond to the simple physical laws of the lever, of gravitation, Ohm's law and Joule's law, etc., while the controversy rages about questions related to the physicist's discussion of the nature of ether and the atom and the so-called law of relativity. Whether one is to use intro-

spection or observation as the method of psychology arises only when one seeks an explanation of mental laws, not while discovering them. For this explanation introspection, observation and speculation on the basis of both and of knowledge obtained from all related fields can, I believe, all be used to advantage. No one method is complete in itself; in most experiments all three are used, no matter to what school the investigator belongs.

One may take as an instance such an experiment as those of Ach on action with the reaction time method. The fundamental result, let us say, is to determine that the response that follows, showing two numbers written one over the other, depends for its character and the time required upon the purpose. That fact is independent of the method used. If one is interested in the antecedents of the movement in consciousness, one must introspect. But raw products of introspection are valueless. One must be assured that the images are essential by repetition of the introspection with the same individual and other individuals under varying conditions. To determine the nature of the purpose and the way it acts one may see if it has any conscious form, and may indulge in physiological speculations, may look for analogies in physiological laws, or one may observe the bodily attitude, the set of the muscles before and during the response. The final acceptance of any explanation will be found to depend upon a harmony of all these observations with each other and with related facts. In any case, the determination of the laws is related to their explanation as observed fact is related to theory in physics or physiology.

The question might well be raised whether the certainty of recognition, of decision and the other processes we have mentioned as constituting the primary facts of

the mental life, are the products of introspection or observation. On this point there is room for difference of opinion. A large number of the processes, recognition, judgment, feeling, seem to be more closely related to introspection; the active processes, on the other hand, the comparison of divided with accumulated repetitions and perceptions, are either derived from observation or a combination of observation and introspection. In addition to these immediately observed, generally recognized mental states and functions there are immediate facts derived both by introspection and by observation aided by experiment. Such are on the one side the awareness of the different sorts of imagery, the course of association, colored hearing and the different synesthesias, and, on the other, the changes in circulation with mental operations, the slight movements, and the larger movements of expression. These and many other immediate facts of consciousness escape the untrained observer or introspector, but are needed to round out the series of mental facts and to aid in the formulation of expansions of other facts and laws.

In brief then there is room in psychology for the greatest variety of standpoints and for all methods, provided only the spirit of live and let live prevails. The science is above the individual and the individual's preference in definition and method. The definition and method in turn must grow out of the science; they are not given once and for all, and the science forced into them. Given a set of facts and laws of fairly general acceptance, the form of statement again is largely a matter of individual preference guided and tested by the interest and comprehension of the group for whom the discussion is intended. As in most sciences a mixture of explanation and theory with bare fact may be used,

or bare facts may be stated and explanation follow or be omitted. Methods that are assumed by the investigators may be with advantage followed in the restatement of their results. But formulation of results and their presentation in a treatise can no more be determined by a priori principles than can the statement of definitions or the prescription of methods. In brief, my plea is for the widest liberty in all respects with a testing of everything by results rather than by formulæ or even by tradition. In the light of the tests so far available it seems to me that defining psychology as the science of behavior and the use of all methods possible under suitable precautions will lead soonest to the end of psychology, the discovery of mental laws and their explanation.

And we have no reason to be ashamed of the progress of the science. More has been done in the discovery of fundamental laws in the last sixty years than in all the preceding centuries from Thales to Fechner, and interesting problems open to our methods of approach on every hand. These laws, the immediate results of experiment, are not in dispute. They have stood the test of repeated investigation, and are accepted on all sides. There is much more difference of opinion about theories, but even here we have made progress. Except for the fact that we still take our theories very seriously, even our theories offer no more occasion for controversy than do theories on similar problems among physiologists, or zoologists or much more than between physicists and chemists.

W. B. PILLSBURY

MRS. HENRY DRAPER

ANNA PALMER DRAPER, widow of Dr. Henry Draper, died on December 8, 1914, at her home in New York City. Her name will always be honorably associated with the science of astro-

physics. It is interesting to note that the wives of two of the men connected with the beginnings of this science played such important parts in the careers of their husbands. Sir William Huggins, who first applied the spectroscope to the stars, had in his wife, the talented Margaret Lindsay, an enthusiastic and capable co-worker during many years of incessant labor. Dr. Draper was also fortunate when, in 1867, he married Mary Anna, the gifted daughter of Courtlandt Palmer, of New York City. For Mrs. Draper not only was her husband's associate in his investigations during the fifteen years of their lives together, but after his early death in 1882, she was able to provide for carrying on his work in a most efficient manner.

It is said that Dr. Draper became especially interested in astronomy in 1867, while attending the meeting of the British Association in Dublin. He was invited by the Earl of Rosse to go with a party to Birr Castle, Parsonstown, to see the famous six-foot reflector. So great was the impression made upon Dr. Draper by this giant telescope that he resolved to construct a similar, although smaller, one for himself. This he did, and in 1867 a reflector of 28-inch diameter was placed in his private observatory at Hastings-on-Hudson. In the summer, Dr. and Mrs. Draper resided at Dobbs Ferry, two miles distant, and it was their custom to drive together to the observatory for the evening work. So great was her interest that he never went to the observatory without her, and in the days of the wet plate, she herself always coated the glass with the collodion. Mrs. Draper told how sometimes after they had been to the observatory and returned to Dobbs Ferry on account of clouds, they would find the sky clearing, and would drive back again two miles to the observatory and recommence work. During the early years of their married life, Dr. Draper was experimenting with the photographs of stellar spectra with his reflector, and in May and August, 1872, he succeeded in photographing the spectrum of Vega, showing four dark lines. This was four years before Huggins obtained a photograph of the dark lines in the

spectrum of this star. In 1878, Dr. Draper organized an expedition to go to Rawlins, Wyoming, for the purpose of observing the total solar eclipse of July 29. Mrs. Draper not only went with him, but also assisted in various ways. Her special duty was to count the seconds during the eclipse and lest the vision might unnerve her, she was put within a tent and therefore saw nothing at all of the wonderful phenomenon. Here she sat patiently and accurately calling out the seconds while the glorious and awe-inspiring spectacle was unfolded. Some of us remember her among those gathered on the roof of Hotel Monticello in Norfolk, Virginia, on May 28, 1900, when without instruments we merely observed the total eclipse for its beauty and grandeur. What memories it must have recalled to her of the distant western land where nearly a quarter of a century before she sat inside the tent and called out the seconds for her distinguished husband!

In the winter, Dr. and Mrs. Draper resided on Madison Avenue, New York City. Here he established a laboratory, connected with the residence by a covered passageway, where his work not dependent on the telescope could be carried on, and where his photographs could be studied. The house, which is between Thirty-ninth and Fortieth Streets, is spacious and well adapted to elaborate entertaining. When originally built by Mr. Palmer, it was the last house in New York City, and he was cautioned by his business friends against investing in property so far away from the center. Mrs. Draper remembered when the old omnibus running on Fifth Avenue went only as far as Thirty-ninth Street, so that when any one alighted and started to walk in their direction they were sure of a visitor.

In November, 1882, when the National Academy of Sciences was meeting in New York City, Dr. and Mrs. Draper entertained the members at a dinner said to have been one of the most brilliant ever given there. As a novelty, Dr. Draper lighted the table with Edison incandescent lights, some of which were immersed in bowls of water. About fifty were present, and at the close of the dinner, Dr. Draper, although suffering from a severe cold,

moved about and talked with several of the guests, among others, Professor E. C. Pickering, director of the Harvard Observatory. They discussed in particular the photographs of stellar spectra Dr. Draper had obtained. Professor Pickering expressed to Dr. Draper his great interest in that work and offered to measure these photographs if they could be sent to Cambridge. Almost immediately after the dinner Dr. Draper was seized with a congestive chill, followed by pneumonia which proved fatal a few days later.

Mrs. Draper, who was in deep distress after this sudden loss, desired to establish some memorial to her husband, and for a few years contemplated the erection of an observatory in New York City. This plan proved impracticable, however, and in 1885, she visited the Harvard Observatory, where Professor Pickering was already photographing stellar spectra along the same line as the work which she considered the most important her husband had done. She thereupon decided to found the memorial in connection with the Harvard Observatory, and gave generous sums each year for its prosecution. At first she thought only of continuing the researches on stellar spectra, but in 1887 she decided to extend the plan to include all available facts about the constitution of the stars. She not only gave liberally of her means to carry on this work, but she always took a great personal interest in it. Until deterred by failing health she visited Harvard Observatory regularly, and personally inspected the progress of the work, giving advice about matters of policy, and being greatly interested in the actual inspection of various stellar spectra. All peculiar or new types were submitted to her, and she often exclaimed with girlish eagerness, "How interesting it must be to do it!"

Mrs. Draper was a friend to many scientific men and frequently gave elaborate entertainments in her spacious home. The old laboratory in New York was fitted up as a lecture or exhibition room and could seat two hundred people. Here many famous men came to lecture to scientific societies and invited guests. Here various scientific exhibitions were placed when she entertained such societies as the

National Academy or the American Astronomical Society. It is quite unusual for women of wealth to entertain in this manner. Few who have such beautiful homes, have such a desire or interest.

The results of the Henry Draper Memorial have been varied. The first catalogue giving the spectra of a large number of stars was published in 1890, and was called the Draper Catalogue. This contained 10,351 spectra. Following closely upon this came detailed discussions of about 5,000 spectra of the brighter northern and southern stars. In 1911, observations were commenced for a New Draper Catalogue, which will contain the spectra of at least 200,000 stars situated over the entire sky. In this work Mrs. Draper was greatly interested until the very last, and wrote encouragingly about its progress.

In the course of the Draper Memorial work, various discoveries have been made, such as 10 novæ, more than 300 variable stars, 59 gaseous nebulae, 91 stars of Class O, and a large number of peculiar spectra. Among the greatest results may be mentioned, the establishment of the true order of stellar evolution, and such discoveries as the connection between variability and changes in spectra, the additional series of hydrogen lines, and the existence of spectroscopic binaries.

Who can predict to what further uses the great collection of plates will be put or what further increase in our knowledge of the sidereal universe will be made by means of the generous endowment left in memory of Henry Draper by his devoted and noble wife.

ANNIE J. CANNON

HARVARD COLLEGE OBSERVATORY,
CAMBRIDGE, MASS.

A NEW GLACIAL PARK

ANNOUNCEMENT has been made through the press of the gift to the New York State Museum of a plot of ground covering seventy-five acres which includes the remarkable Green Lake near Jamesville, N. Y., with its series of abandoned cataracts, rock channels and dry plunge-basins. This spot is not only extremely

picturesque, but now that the significance of its singular conformation has been pretty well worked out by the labors of E. C. Quereau, and more particularly by Professor H. L. Fairchild, it constitutes a very extraordinary, if not unique, geological record.

In the course of Professor Fairchild's work upon the Pleistocene geology of New York state, he demonstrated very clearly and in detail the accuracy of Mr. Quereau's suggestion that in the retreat of the ice mantle the outflow of the glacial waters was by way of tremendous rivers moving eastward into the Mohawk-Hudson drainage, and here one of these streams cut its rock gorge in the limestones of the Helderberg escarpment and left a series of plunge-basins beneath great cataracts which surpassed the dimensions, as they must have equalled the dignity and grandeur, of Niagara.

The Green Lake or Jamesville Lake, which lies on the property now thus reserved, is surrounded on all but its eastern side by an amphitheater of sheer limestone cliffs rising to a height of nearly 200 feet, and the depth of the lake is stated by the former owner of the property to be not less than 100 feet. While water still fills this ancient plunge-basin, it is water of a deep emerald hue, without visible outlet or inlet. Westward of this escarpment is a smaller and dry plunge-basin with its abandoned cataract cliff and with rocky channels connecting it with the larger basin, and from the Green Lake eastward is the old open discharge into the other stream courses and cataracts lying beyond Jamesville in the vicinity of Fayetteville.

Aside from the extraordinarily clear and wonderfully effective geological record displayed in this place, the spot has additional scientific interest as its rocks are the resort of many rare ferns and flowering plants which have long attracted the botanist.

The menace of commerce, expressed in the ever-increasing demand for the conversion of limestone into cement, threatened this wonderful spot, and the intervention of the donor, who saved it from destruction, is a particularly gracious act inasmuch as it conserves a place of high scientific and educational interest.

The property is given to the regents of the university for the State Museum by Mrs. Mary Clark Thompson, of New York, and presented in the name of her father, Myron H. Clark, a former governor of that state, and by her desire it is to be known as the "Clark Reservation."

It may be added that this reservation lies about four miles to the southeast of Syracuse on the Seneca Turnpike, a new state road, and is also easily accessible from Jamesville which can be reached from Syracuse by trolley.

JOHN M. CLARKE

ALBANY, N. Y.,
March 3, 1915

THE UNITED STATES GEOLOGICAL SURVEY AT THE PANAMA EXPOSITION

THE exhibit occupies a space 82 by 78 feet in the Palace of Mines and Metallurgy, flanked on one side by the exhibit of the Bureau of Mines and on another by the Alaskan exhibit, for which also the survey has been in a measure responsible. The central feature of the exhibit is a booth, containing stage-like settings of a scene, partly modeled and partly painted. The first represents an undeveloped district in the arid west being studied by the survey. Topographers are at work with their instruments on the headlands; geologists have stripped a bed of coal and are taking a sample for analysis; and other geologists are studying the rocks. In the foreground is an automatic gage beside the river that comes out of the picture toward the observer. Farther back, a stream gager is measuring the stream. In the background is a camp and pack train. The second scene shows the same district after development. The results of the stream gaging have been utilized in planning a power plant that shows in the distance and an irrigation project that covers the valley floor. The coal bed is being mined on one side; an oil field is under development elsewhere; a sandstone bed is being quarried in the foreground; mining and milling are in progress in the mountains; a town has been built, and roads, railroads, and other evidences of civilization abound.

Behind the scenes, in the same booth but

facing the ends, are recessed screens, on one of which are shown pictures illustrating the different kinds of survey work and the part they play in the development of the country. On the other screen are shown several series of pictures.

At one end of the space is shown the per capita production of minerals in the United States in 1880, about the time of the Centennial Exposition, and of the organization of the survey, and in 1913, the period between these dates practically covering the past work of the United States Geological Survey. The exhibit consists of one 97-millionth of the actual production of each mineral in 1913 and one 48-millionth of the production in 1880.

The space along one of the outside aisles is devoted to a series of cases, illustrating what our common things are made of, what the raw material looks like as it is obtained from the earth, and where it occurs in the United States. For example, many of the familiar household articles are there, such as an aluminum saucepan, an electric-bulb filament, and a fountain-pen point; and above each article is shown the mineral from which it is made, traced back to the ore, and then a map of the United States, showing where the ores occur. Most of these individual maps have been prepared especially for this exhibit.

At the west end of the space is an exhibit of the power and fuel resources of the United States, including maps showing the distribution of the black shale from which oil is derived and the apparatus used in the field in determining the shales that are worth studying.

In order to show the transparencies included in the exhibit to the best advantage, arcades resembling mine entrances have been built at the corners of the space. The methods of work in the survey are illustrated by a series of cases showing by a set of partial results how maps are made and other features of the work.

In the portion of the exhibit relating to water resources is a display of automatic gages being run by clock work and recording the fluctuating height of water in a tank.

One feature of the exhibit is the stereoscopic pictures, resembling the old mutoscope views but of a modernized type. These will be arranged in boxes of fifty each on a table at which one may sit and study leisurely various features of survey work. There are also shown four series of pictures of the Grand Canyon and Rocky Mountain region, taken in the early days of the geological survey by the famous photographers Jackson and Hillers.

Other cases show the gem minerals, the rare mineral ores, etc.

SCIENTIFIC NOTES AND NEWS

COL. GEORGE W. GOETHALS has been made a major-general of the line in recognition of his services in building the Panama Canal. Brig.-Gen. William C. Gorgas, surgeon-general, has been made major-general in the medical department. Col. Harry F. Hodges and Lieut.-Col. William L. Sibert, United States Corps of Engineers, have been promoted to be brigadier-generals. The bill providing for their promotions extended the thanks of congress to the officers.

UNDER the leadership of Dr. Hiram Bingham, the National Geographic Society-Yale University Peruvian Expedition sailed from New York on March 3 to continue its work in the Andean Mountains. Members who left New York on this expedition are: Director, Hiram Bingham, Yale University; geologist, Herbert E. Gregory, Ph.D., Silliman professor of geology in Yale University, geologist of the 1912 expedition; naturalist, Edmund Heller, naturalist of the Smithsonian's African expedition, under the leadership of Colonel Roosevelt; botanist, O. F. Cook, Ph.D., of the United States Department of Agriculture; chief engineer, Ellwood O. Erdis, of the 1912 expedition; topographer, Edwin L. Anderson; chief assistant and interpreter, Osgood Hardy, M.A., of the 1912 expedition; assistant topographer, C. F. Westerberg, B.S., and several assistants.

MISS KATHARINE LILLY, head nurse of the department of surgery of the Rockefeller Institute for Medical Research, has gone to

France to assist Dr. Alexis Carrel, of the institute, who recently has been detached from the Lyons Hospital and placed in charge of a hospital at Compiègne, France, near the northern line of battle. Dr. H. D. Dakin, the biological chemist, who worked some years in this country, has also joined Dr. Carrel.

PRESIDENT RAYMOND A. PEARSON, of the State Agricultural College at Ames, Iowa, has decided not to accept the offer of Governor Whitman, of New York, to become state commissioner of agriculture to succeed Mr. Calvin Hudson. Dr. Pearson was commissioner of agriculture under Governor Hughes.

MR. WILLET M. HAYES, formerly assistant secretary of agriculture, has returned from a year's service as adviser to the government of the Argentine Republic and of the Province of Tucuman.

Dr. and Mrs. N. L. Britton, of the New York Botanical Garden, Mrs. N. Wille, Mr. John F. Cowell, director of the Buffalo Botanical Garden, and Mr. Stewardson Brown, of the Philadelphia Academy of Natural Science, are in Porto Rico engaged in botanical explorations.

DR. JANET T. HOWELL, daughter of Dr. William Howell, professor of physiology in the Johns Hopkins Medical School, has been awarded the Sarah Berliner Fellowship for Women. This fellowship carries with it a gift of \$1,000 to enable the recipient to engage in research work in physics, chemistry or biology. Dr. Howell received the A.B. from Bryn Mawr College in 1910, and the Ph.D. from the Johns Hopkins University in 1913. She was holder of the Helen Schaffer Huff research fellowship in physics at Bryn Mawr College during 1913-14 and this year she holds the position of lecturer in physics at Bryn Mawr College, taking the place of Professor James Barnes.

ON February 26, Professor Alexander Smith, of Columbia University, delivered a lecture to the Boylston Chemical Club of Harvard University on "The Forms of Sulphur and Their Relations."

PROFESSOR W. K. HATT, of Purdue University, lectured at the University of Illinois on

February 24 on the subject of "Flood Protection in Indiana."

IRA O. BAKER, professor of civil engineering in the University of Illinois, lectured recently before the students of the Short Course in Highway Engineering at the University of Michigan. His subject was "Selecting the Road Surface."

DR. WALTER HOUGH, curator of ethnology, U. S. National Museum, gave an address before the California Academy of Sciences on February 17, on "Explorations of a Sacred Cave in Arizona."

DR. BARTON W. EVERMANN, director of the Museum of the California Academy of Sciences, gave the Sigma Xi lecture at the University of California on February 24. His subject was "The Conservation of the California Elk."

DR. RICHARD MILLS PEARCE, professor of research medicine in the University of Pennsylvania, addressed the Buffalo Academy of Medicine on Wednesday evening, February 24, on "Experimental Studies of the Spleen in its Relation to Anemia, Hemolysis and Hemolytic Jaundice." A reception to the speaker followed the lecture.

WE learn from *Nature* that M. Louis Moissan, son of the late Professor Henri Moissan, and assistant at the Ecole supérieure de Pharmacie at Paris, who died on the field of battle on August 10, has left to his school, in addition to the scientific books and apparatus of his father, the capital sum of 200,000 francs for the foundation of two prizes—one for chemistry (prix Moissan), and one for pharmacy (prix Lugan), in memory respectively of his father and his mother, née Lugan.

DR. T. WREBLEY MILLS, emeritus professor of physiology in McGill University, died in London on February 14.

PROFESSOR JAMES GEIKIE, the distinguished geologist, died in Edinburgh, on March 2, in his seventy-sixth year. He entered the British Geological Survey in 1861 and was called to the Murchison chair of geology at Edinburgh University in 1882, succeeding his brother, Sir Archibald Geikie.

DR. RICHARD WEITZENBÖCK, aged thirty years, docent for chemistry at Gratz, has been killed in the war.

A DESPATCH from Rome states that all physicians in Vienna who are under fifty years of age have been ordered by an imperial decree to join the army medical corps.

THE Rockefeller Institute for Medical Research has appropriated \$20,000 to be used under the institute's direction to further medical research work under war conditions, and is equipping Dr. Carrel's new hospital in France with apparatus for research work on pathological, bacteriological, surgical and chemical conditions.

THE New England Association of Chemistry Teachers held its fifty-second regular meeting on February 27, at the Roxbury Latin School, when an address entitled "Some possible items, new and old, for the course in elementary chemistry," was given by Professor Alexander Smith, head of the department of chemistry in Columbia University. At the request of the executive committee Professor Smith discussed several topics, such as: Action of air in the Bunsen burner flame; colloidal suspensions; cause of valence, electrons; the shortest route to atomic weights; the distinction between physical and chemical change; and new view of a crystalline solid. Several experiments were performed to illustrate these subjects. The members who were present in large numbers discussed the value of these topics in an elementary course in chemistry.

THE U. S. Civil Service Commission announces an examination for metallographist, for men only, to fill a vacancy in this position for service in the Engineering Experiment Station, Naval Academy, Annapolis, Maryland, at a salary of \$2,500. The duties of this position will be (a) to direct the preparation of metal specimens for microscopic examination and the photographing of the same, and to interpret the appearance of specimens under the microscope; (b) to prescribe correct heat treatment for steel specimens which have not had proper treatment; (c) to make and interpret the various standard physical tests applied

to metal specimens; (d) to investigate miscellaneous problems that may arise in the course of naval practise, such as the cracking of the tin linings of copper cooking kettles, imperfect welds, various processes of galvanizing, etc.; (e) to investigate the properties of various alloys of metal; (f) occasionally to make a chemical analysis of metallic substances. The degree of Ph.D. from a college or university of recognized standing, and at least five years' experience since receiving the bachelor's degree, such experience to have included the use of the microscope in the examination of metals, and the making and interpretation of photomicrographs of metals, are prerequisites for consideration for this position.

A SYSTEMATIC study of Missouri River and its tributaries is being carried on by the United States Geological Survey. Considering the varied character of the streams of the Missouri River basin and their great economic value for irrigation, power, and other purposes, the investigation is one of the highest importance. The water supply of this great drainage area is the subject of a publication recently issued by the Geological Survey, entitled "Surface Water Supply of the Missouri River Basin, 1912" (Water-Supply Paper 326), by W. A. Lamb, Robert Follansbee, and H. D. Padgett. This report contains the records of flow at 130 permanent stations of the survey during the year 1912, data which are necessary to every form of water development, whether it be water power, navigation, irrigation, or domestic water supply. Some of the tributary streams are exceedingly variable in flow; others, like the Niobrara in Nebraska, are remarkably uniform. The Missouri proper is formed in southwestern Montana by the junction of three streams which were discovered by Lewis and Clark in 1806 and were named by them Jefferson, Madison and Gallatin rivers. Of these three Jefferson River drains the largest area and is considered the continuation of the main stream. This part of Montana is mountainous and affords many excellent water-power sites. Among the principal tributaries of the Missouri are the Marias, Mussellsbell, Yellowstone, Cheyenne,

Platte and Kansas. The western part of the basin is in the arid belt and the eastern part is in the semiarid and humid regions. Ten states of the Union are drained in part by Missouri River. Rising at the Red Rock Lakes, at an elevation of 8,700 feet above sea level, this stream descends through the Rocky Mountains and emerges on the broad prairie land a few miles below the city of Great Falls, Montana. From that point it is accounted a navigable stream with an easy grade, and in passing through the Dakotas and along the borders of Nebraska, Kansas and Iowa it receives the flow of great tributaries, so that as it crosses the State of Missouri and joins the Mississippi a short distance above St. Louis it becomes one of the large rivers of the world. Its total drainage area is about 492,000 square miles in extent and comprises, in addition to the states above mentioned, large areas in Wyoming and Colorado and a smaller area in the southwestern part of Minnesota.

THE Michigan College of Mines has received a collection of minerals from the Shattuck Cave, near Bisbee, Arizona, one of the wonders of the mining world. This cave was opened in 1913 by a drift on the third level of the Shattuck Mine. When the miner who had been drifting in this part of the level returned one night after a heavy blast, he found that the working face had entirely disappeared and that before him was a great opening reaching farther than his light would shine. Looking upward he could see tiny lights flashing and believing that they were stars he ran back to the shaft, declaring that he had blasted a hole clear through to surface. Mine officials investigated at once and found that a great natural cavern had been opened up, circular in shape, 340 feet in diameter and 175 feet high. It was a virtual fairyland of beauty, myriads of crystals in the roof reflecting back the lights from the miners' lamps. Walls, roof and floor were covered with great clusters of crystals, and near the center of the cavern a cluster of stalactites hung from the ceiling in the form of a great chandelier 40 feet long. The crystals were for the most part pure white, but in places where the filtering waters had contained

iron and copper, the beauty was enhanced by great transparent stalactites and stalagmites, some ruby red, others a clear emerald green or azure blue. The mining company illuminated the cave with electricity and has allowed thousands of visitors the privilege of seeing it. An attempt was made to have the Smithsonian Institution at Washington remove and reproduce a portion of the cave, but nothing came of it. It is because the mine operators have now found it necessary to fill the cave with waste rock that the Shattuck-Arizona Mining Company sent the specimens to the College of Mines. Superintendent Arthur Houle, of the Shattuck Company, is a brother of Professor A. J. Houle of the college.

UNIVERSITY AND EDUCATIONAL NEWS

THE Massachusetts committee on education voted unanimously on February 25 in favor of "taking initial steps toward the establishment of a state university."

ROBERT FLEISHER has left a bequest of a million marks to the University of Frankfurt.

DR. FRANK J. GOODNOW will be formally inaugurated president of the Johns Hopkins University on or about May 20. It is planned to give the occasion a double significance in inaugurating the third president of the university and formally dedicating the new site at Homewood.

AT Smith College the following promotions have been made: from assistant professor to associate professor, Inez Whipple Wilder, A.M., department of zoology; from instructor to assistant professor, Mary Murray Hopkins, A.M., department of astronomy, and Grace Neal Dolson, Ph.D., department of philosophy.

THE senate of the University of London has conferred, as we learn from *Nature*, the titles of professor and reader in the university upon the following: Dr. A. L. Bowley (London School of Economics), statistics; Mr. L. R. Dicksee (London School of Economics), accounting and business organization; Mr. J. E. S. Frazer (St. Mary's Hospital Medical School), anatomy; Dr. T. M. Lowry (Guy's

Hospital Medical School), chemistry; Mr. J. H. Morgan (University College and the London School of Economics), constitutional law; Dr. W. J. R. Simpson (King's College), hygiene and public health; Mr. J. H. Thomas (University College), sculpture; and Mr. G. Wallas (London School of Economics), political science.

DISCUSSION AND CORRESPONDENCE

HEADSHIP AND ORGANIZATION OF CLINICAL DEPARTMENTS OF FIRST-CLASS MEDICAL SCHOOLS

TO THE EDITOR OF SCIENCE: In the October 30, 1914, number of SCIENCE there is a very interesting and timely article by Dr. Meltzer, of the Rockefeller Institute, on the reorganization of clinical teaching in this country, "Headship and Organization of Clinical Departments of First-class Medical Schools." The subject is a very important one and I feel sure that it will interest the many medical men who have the opportunity of reading your journal. Dr. Meltzer refers in his letter, which is written to a university president, to the report of the Council on Medical Education of the American Medical Association made to the House of Delegates of the A. M. A. in June of last year. He takes occasion to criticize in his letter several statements made in this report, and especially the statement "that the medical school very properly demands that its clinical teachers be men who are recognized as authorities in their special fields, both by the profession and the community," and he further objects to the use of the term "grotesque" as referred to a plan in which it is proposed that clinical teachers may do private practise, but that fees from such practise are to be turned into the university treasury. He also questions in advance the value of a report on the reorganization of clinical teaching that is to be made by a committee of the well-known clinical teachers to whom this subject has been referred by the Council on Medical Education.

As chairman of the Council on Medical Education I am very glad that this important subject is being discussed in the columns of such an influential journal as SCIENCE and by such an able physician and research worker

as Dr. Meltzer. I feel, however, that the readers of SCIENCE and college presidents and trustees could not form an accurate view of the position taken by the American Medical Association from Dr. Meltzer's letter alone, and without reading the portion of the report of the Council on Medical Education referring to this subject, and therefore am enclosing this special part of our report from page 15 to page 17.

In the reorganization of our medical schools one of the most pressing needs is that of placing the clinical departments on a more satisfactory basis. Little has as yet been done in this country with this problem, and the time has arrived when the medical profession and the medical schools must take up this matter vigorously and formulate a general plan of organization of our clinical departments and urge its adoption. With this in view the Council on Medical Education has appointed a strong committee of ten clinicians, who have had great experience in teaching and who are regarded as authorities in their special departments and in medical education, to study this subject and report to the conference on medical education.

The organization of a clinical department is a more complex subject than that of a department like anatomy, or physiology, where teaching and research are the functions demanded.

In clinical work the head of the department and his associates must be three things; first, great physicians in their special field; second, trained teachers; and third, research workers. The medical school very properly demands that their clinical teachers be men who are recognized as authorities in their special fields, both by the profession and by the community. In the organization of a clinical department this fact must not be lost sight of and whatever plan is adopted must make it possible for the clinical teachers to remain the great authorities in their special fields both in the eyes of the profession and of the public.

The plan adopted by the German universities has been on the whole most satisfactory. There a professor in a clinical department is in every sense a university professor just as

much as the professor of chemistry or of physics. His university work commands his time. He must allow nothing to interfere with his teaching, his clinical work in the hospital or his research, and he devotes on the average quite as much time to his university work as does his colleague in chemistry or in mathematics. In addition to this, however, he devotes some time each day to private practise by which he maintains his position before the profession and the public as a great specialist. This can be done without neglecting his university position. In fact, if he does not remain the great physician, he ceases to be of as much value either to his students or to his university. On the other hand, if he should neglect his university work because of the time he devoted to private practise, his services would be dispensed with.

This problem of clinical teaching has been taken up during the year by the General Education Board and, as a result, an interesting experiment is to be tried at Johns Hopkins and possibly at one or two other places. The General Education Board has given Johns Hopkins \$1,500,000 endowment with which to pay salaries to the departments of medicine, surgery and pediatrics. The position is taken in this experiment that the head of a clinical department should be given a very large salary and should receive no fees for private practise. It was recognized at once that the rich should not be deprived of the services of these experts, so the grotesque plan is proposed that these men may do private practise, but that fees from that practise are to be turned into the university treasury and not into their own pockets. [As will be seen by the context the word "grotesque" does not apply to the plan as a whole but is used to characterize that part of it which proposes that these clinical teachers may do private practise but are not permitted to receive any fees for these services, the understanding being that the fees are to be assessed and collected and appropriated by the university or hospital. I desire to assume the full responsibility for this particular portion of the report and to submit that the term "grotesque" is an exceedingly mild one to

characterize such an unethical and illegal scheme. That the fees for the peculiarly individual and personal service rendered by a physician or surgeon to his patient should be appropriated by any institution and not go direct to the medical man rendering such service is clearly unethical. It is equally clear that it is illegal, as the institution would have no standing whatever in court if it sought to collect for itself the fees for such service. It is interesting to note in this connection that although these propositions are perfectly clear to men who are practising medicine, they are not as self-evident to non-clinical and non-medical men who are not in a position to understand the rights and interests of the medical profession.]

The men who proposed this plan, and provided the money necessary to make the experiment, are non-medical men; they do not have the medical point of view and they do not understand the complex functions demanded of the clinical teacher.

This plan has not been well received by the clinical teachers and finds its supporters almost entirely among the laboratory men. It is difficult to understand if the teachers in a medical school are to be placed on salaries and not permitted to receive any compensation for outside work, why the clinical teacher should be given a very large salary and his colleague in anatomy or in pathology a comparatively small one. The sweating of the scientific men who have devoted their lives to teaching and research on miserable salaries is notorious. Advantage has been taken of the fact that their scientific enthusiasm would hold them to their work and they are often as underpaid, comparatively, as the workers in a sweat shop. Surely, if the medical department of a university receives large endowments for the payment of salaries, the men teaching in the laboratory sciences should receive the first consideration. Again, if a clinical department obtained large sums for salaries, why should they pay a very large salary to the head of the department who in a very limited amount of time devoted to practise could obtain for his services much more than the amount of such

salary? Would it not be better to devote the available money to paying several younger men from 25 to 35 years of age—their more productive years—to devote practically all their time to teaching and research? Fortunately for the plan, the men who are responsible for it recognize that it is an experiment and frankly advise that it be not adopted by other medical colleges until it has been tried out on Hopkins.

The fact that such a plan has been seriously proposed by laymen interested in education emphasizes the necessity of a thorough reorganization of our scheme of clinical teaching along lines to be determined and agreed on by a committee of our best clinical teachers.

I should like to add the following comment.

First, that the Council of Medical Education believes that one of the most pressing needs is that of the reorganization of our clinical departments on a more satisfactory basis.

Second, the Council of Medical Education has taken the position that this important subject of the reorganization of clinical teaching should be submitted to a committee of experts, men who are recognized as great clinical teachers and who are familiar with the problems of clinical medicine. This committee is composed of the following men: Dr. V. C. Vaughan, University of Michigan, President of the American Medical Association; Dr. Geo. Armstrong, McGill University; Dr. John Finney, Johns Hopkins University; Dr. John Clark, University of Pennsylvania; Dr. W. J. Mayo, trustee of the University of Minnesota; Dr. Geo. deSchweinitz, University of Pennsylvania; Dr. Frank Billings, Rush Medical College, University of Chicago; Dr. Harvey Osahing, Harvard University; Dr. Geo. Dock, Washington University, and Dr. Saml. Lambert, Columbia University.

The committee is at present working on this problem. The Council on Medical Education does not know as yet what the findings of this committee will be. We believe, however, that the report of this committee will be of greater value than would the report on this particular subject of a committee of university presidents, professors in the science departments of

universities, professors of the laboratory branches such as embryology, chemistry or physiology in a medical school, or men who are devoting their lives to the problems of medical research, but who are not in touch with clinical medicine. Would it not be well for university presidents, university trustees and medical faculties who contemplate reorganizing their clinical departments to await the findings of this committee representing the American Medical Association? The subject was discussed February 16, 1915, at the annual conference on medical education held in Chicago and the final report will be made to the house of delegates at the June meeting of the American Medical Association.

ARTHUR DEAN BEVAN

SOIL NITRATES

TO THE EDITOR OF SCIENCE: In the reviews of an article¹ by Mr. Wright and myself appearing in a monthly bulletin of the International Institute of Agriculture² and the *Chemical Abstracts* of the American Chemical Society,³ the point of view supported by our paper is not fully recognized. One review refers to the malnutrition of citrus trees as resulting from the toxic effects of superabundant nitrates, and the other refers especially to the production of malnutrition from the denitrification of soil nitrates. We presented the data of our experimental studies in California in some detail in order to draw attention to what we believe to be an important phenomenon, namely, that probably identical symptoms of malnutrition result either from superabundant nitrates which we regard as one phase of the so-called "alkali" poisoning and by nitrogen starvation which may re-

SCIENTIFIC BOOKS

Water Reptiles of the Past and Present. By SAMUEL WENDELL WILLISTON, professor of paleontology in the University of Chicago. University of Chicago Press, 1914. Pp. vii + 251, with 131 text-figures.

This interesting volume summarizes in a most authoritative manner our knowledge of the reptiles which have become adapted to aquatic life, and it also includes a chapter on the classification of reptiles, a subject upon which Professor Williston, with his forty years of special study, is abundantly fitted to speak.

In his introduction the author speaks earnestly in the defense of reptiles, which are so often of ill repute as cold, gliding, treacherous and venomous creatures shunning sunlight and always ready to poison. As a matter of fact, but few reptiles possess these evil propensities, for, aside from the venomous serpents, there are but two poisonous reptiles known, and the vast majority are not only innocent of all offense toward man, but are often useful to him. More than four thousand reptiles are living, representing, however, but four of the fifteen orders which were formerly alive. The terse definition of a reptile as a cold-blooded, backboneed animal which breathes air throughout life is not surely correct, since it has been believed that certain extinct ones may have been warm-blooded.

While there are very marked distinctions of structure between the amphibians and the reptiles, there can be no doubt that the early amphibian ancestors of the modern toads, frogs and salamanders were also the ancestors of all living and extinct reptiles. This is proved by the fact that discoveries of recent years have bridged over nearly all the essential differences between the two classes so completely that many forms can not be classified unless one has their nearly complete skeletons. In the case of some of the oldest amphibia, the

Stegocephalians, we know that they were water-breathers during part of their lives, because distinct impressions of their gills have been preserved, but we are not so sure that some of the more highly developed kinds were not air-breathers from the time they left the egg; if this be true, our definition of a reptile as distinct from an amphibian is rendered still less secure. We are quite certain that from some of the early extinct reptiles—probably the immediate forebears of the great dinosaurs—the class of birds arose, while another group of primitive reptiles, called the Theriodontia, and known chiefly from Africa, gave rise to the mammals.

The classification of reptiles is still a matter of much doubt and uncertainty, no two authors agreeing on the number of orders or the rank of many forms. Many strange and unclassifiable types which have come to light in North America, South Africa and Europe have thrown doubt on all previous classification schemes and have weakened our faith in all attempts to trace out the genealogies of the reptilian orders; and classification is merely genealogy. It is only the paleontologist who is competent to express opinions concerning the larger principles of classification of organisms and especially the classification of reptiles. The neozoologist, ignorant of extinct forms, can only hazard guesses and conjectures as to the relationships of the larger groups, for he has only the specialized or decadent remnants of past faunas upon which to base his opinions.

Williston's scheme of classification differs only in minor details from the more conservative of the generally accepted views, and those differences are, for the most part, the writer's own opinions, to be taken for what they are worth. It may be said decisively that no classification of the reptiles into major groups, into superfamilies or subclasses that has so far been proposed is worthy of acceptance; there is no such subclass as the Diapsida or Synapsida, for instance.

Williston recognizes and briefly diagnoses fifteen orders, of which three groups, the Proganosauria, Protorosauria and Thalattoosauria, are provisionally given this rank.

The third chapter is an illuminating discussion of the skeleton of reptiles, in which the principal elements are not only fully described, but illustrated by the author's drawings.

The chapter on the Age of Reptiles contains a chart showing the range in time of the various reptilian suborders, beginning with the Carboniferous. Each important horizon is taken up in turn and the character of the sedimentation and location of the chief exposures discussed. This section is illustrated by Williston's restorations of various Permo-Carboniferous reptiles.

All this is by way of preparation for the main theme of the book—that of the adaptation of reptiles to aquatic life—and the fifth chapter discusses the problem in general, with the principal structural changes which water-living brings about, comparing the reptiles in their modification with other important aquatic types. Then in regular sequence the water-inhabiting orders are discussed: the *Sauropterygia*, *Lystrosaurus* among the *Anomodontia*, the *Ichthyosauria* in which the summit of aquatic adaptation is reached, *Mesosaurus* of the *Proganosauria*, *Pleurosaurus* of the *Protosauria*, many of the *Squamata*, especially the marine iguana *Amblyrhynchus* of the Galapagos Islands, and the *Agalosaurs* and *Mosasaurs*, our knowledge of the last named being largely due to the author's own researches.

Another chapter treats of the *Thalattosauria* recently described by Dr. J. C. Merriam, while the *Rhynchocephalia* are represented by *Champsosaurus*. Crocodile-like forms are included under two orders, *Parasuchia* and *Crocodylia*, *Geosaurus*, an Upper Jurassic crocodile, going to the extreme and developing an ichthyosaur-like tail for swimming. The final chapter treats of the *Chelonina*, the most sharply distinguished order of reptiles and the one which had the most uniformly continuous and uneventful history from the Triassic to the present time.

This book is a thoughtful exposition of the entire subject from a master hand, and while necessarily technical in part, is written in

such a style as to be eminently readable. It departs from the great majority of popular books of "ancient monsters" because it is written by one who has a world-wide reputation as an authority on the subject of which he treats.

In view of the success of the present volume and of the preceding "*American Permian Vertebrates*," Williston's announced volume on the evolution of the reptiles is anxiously awaited.

RICHARD S. LULL

YALE UNIVERSITY,
February 1, 1915

Festschrift Max Bauer zum siebenzigsten Geburtstag gewidmet. Edited by R. BRAUNS. Stuttgart, E. Schweizerbartsche Verlagsbuchhandlung, 1914. Pp. viii + 568, portrait, 32 plates and 47 text-figures; *Neues Jahrbuch für Mineralogie, Geologie und Paläontologie*, Beilage Band XXXIX.

As a richly deserved and most fitting tribute of regard and esteem to a scientist of distinguished merit, the recent issue of a supplementary volume of the "*Neues Jahrbuch für Mineralogie, Geologie und Paläontologie*," in honor of the seventieth anniversary of the birth of Herrn Geheimrath Professor Dr. Max Bauer, founder of the Mineralogical Institute of the University of Marburg, enlists the sympathies of all interested in scientific progress, more especially in the domain of mineralogy. This handsome octavo volume extends to nearly 600 pages, and is embellished with an excellent likeness of Professor Bauer, as well as with 32 well-executed plates and 47 text-figures illustrating the subject-matter of the various articles. The dedication from his friends, co-workers and students gives warm expression to their appreciation of his services in the cause of science.

Of the many valuable papers in this testimonial "*Festschrift*" we can do little more than cite the titles or indicate the subject-matter. Professor Alfred Bergeot, of Königsberg, treats of the structure of the manganese deposits at Meggen-an-der-Lenne, and emphasizes their value in a determination of the geological formation of this region (pp. 1-63);

Dr. R. Brauns studies the scapolite-bearing eruptive rocks in the lake region of Laach (pp. 79-126). A full and interesting paper on the discovery of a small crystal-grotto in pegmatitic granite of Wildensau, Saxon Vogtland (pp. 126-185, 5 plates and 4 figs.), is contributed by Dr. Ross Bruno. A study, with analyses of the basalts of Marburg, is offered by Professor Arthur Schwantke (pp. 531-567, 8 plates and 5 figs.), and one on the origin of talc deposits by Professor C. Doelter of Vienna (pp. 521-530). Much interesting information as to the nephrite of Harzburg is supplied by Dr. J. Uhlig, of Bonn.

There is also a paper on the monazite of Dattas, Diamantina, State of Minas Geraes, Brazil, by Dr. K. Busz (pp. 482-499); the methods employed for investigating the molecular structure of silicate solutions are treated of by Dr. H. E. Boeke (pp. 64-78) and a brief account of a polishing apparatus for crystal planes is given by Dr. Victor Goldschmidt, of Heidelberg (pp. 186-192). This is followed by a paper on an instance of the deposition of sodium in contact-metamorphism at Lange-sundsfjord, Norway, by V. M. Goldschmidt, of Kristiania (pp. 193-224), and a study of certain aspects of monohydrate lithium-sulphates, by Dr. A. Johnsen (pp. 500-520). The *aeolite-syenite-laeolite* of the Sierra de Monachique in southern Portugal is the subject chosen by Dr. Erich Keiser, of Giessen (pp. 225-267, with geological sketch map on Plate XII); Dr. Eduard Raphael Liesegang treats of *pseudoclase* (pp. 268-276); the nomenclature of crystal forms is studied by Dr. L. Milch (pp. 277-289), and a paper on the granites of the Carpathians is contributed by Dr. J. Morozewicz (pp. 290-345).

In his account of the tin deposits of Tasmania (pp. 346-387) Dr. Fritz Noething expresses the opinion that these deposits are either entirely or in great part of marine, not of fluvial origin. This paper is followed by one on colloidal silicates by Dr. F. Rinne (pp. 388-414). Besides his study of the nephrite of Harzburg, Dr. J. Uhlig reports on a diopside with manganese from the same region (pp. 446-449). Less strictly scientific, but extremely interesting as a contribution to

the historic description of a celebrated volcano, is the paper by Dr. K. Sapper on the "Hell of Masaya," presenting a synopsis of the accounts of this Nicaraguan volcano given by the early Spanish visitors to this region, several of whom ascended to the mouth of the crater, beginning with the ascent made in 1529 by Gonzalo Fernandez de Oviedo y Valdés.

The mere recital of the many subjects treated of in this volume is a sufficient indication of its wide range and of the variety and value of its contents, rendering it an important contribution to mineralogical science.

The birthplace of Professor Bauer was the village of Gnadenthal, near Schwabisch-Hall, in Wurtemberg; at the date of his birth, September 13, 1844, his father was the pastor of the community. Two years later, Pastor Bauer was transferred to Aalau and then to Kunzelsau and Weinberg; in this last-named place he was acting as "superintendent" at the time of his death in 1872.¹

Max Hermann Bauer was the eldest of eight children, six of whom still survive. In 1859, when fifteen years old, he entered the Polytechnic school in Stuttgart, where he devoted himself to the study of mining engineering and metallurgy, his interest in this latter branch having been awakened by frequent visits to the large iron foundries and mines of Wasseraalengen quite near Aalau, with whose officials his parents were well acquainted. However, the question soon arose whether this field would offer sufficient guarantees for the future in the case of one without private fortune. Of the extremely conservative ideas prevailing in his immediate neighborhood Dr. Bauer writes: "In my native place at that time people usually felt themselves confined to the narrow limits of their birthplace; the idea of seeking elsewhere the more favorable opportunities lacking there, was regarded as eccentric."

Hence the young student, after successfully passing his examination in the Stuttgart Polytechnicum in 1862, turned his attention more especially to mathematics and the natural sciences, which he pursued from 1863 to 1865 at

¹ These autobiographical details were very kindly furnished to me by Professor Bauer.

the University of Tübingen, with the intention of qualifying himself for instruction. When this course was completed, he became an instructor, successively, in several Real-schulen in Württemberg. His services in this capacity were so highly appreciated that the government sent him to Paris in 1867 to perfect himself in the French language.

However, his growing interest in mineralogy and geology gradually induced him to devote more and more of his time to these studies, and the doctor's degree was awarded him by Tübingen University for a dissertation entitled: "Die Braunsteingänge von Neuenberg." Another period of study in Tübingen in 1868 enabled him to profit by the instruction of Professor Eduard Reusch, an authority on crystallography, and for a time Dr. Bauer confined himself essentially to this science, while not neglecting geology and paleontology. Some of the results of his crystallographic investigations were presented in his first treatise, on mica, issued in 1869, while a number of articles on geology and paleontology as well as his participation for a score of years in the preparation of the special geological map of Prussia, on a scale of 1:25,000, showed his proficiency in these sciences.

The autumn of 1868 found Dr. Bauer in Berlin pursuing a course of study in the mineralogical institute there under the direction of Gustav Rose. The outbreak of the Franco-Prussian War in July, 1870, interrupted these studies, as Dr. Bauer volunteered in defence of his Fatherland. After the termination of this war he was active for a time in Munich and then again in Tübingen, proceeding thence to Göttingen, where he became privat docent of mineralogy and geology. In 1872 he occupied a similar position in Berlin University, also becoming first assistant in the mineralogical institute. From Berlin, in 1875, he was called to the University of Königsberg as ordinary professor of mineralogy and geology. These studies had for a time been somewhat neglected in this university, and there was a sad lack of instruments, books and specimens; not a single fossil was to be seen. This condition of things was entirely changed by Professor Bauer during the one and a half

years of his stay. While his lectures embraced the entire field of mineralogy, geology and paleontology, his own personal studies were especially concerned with crystallography and crystallographico-physical investigations. It was toward the close of this residence in Königsberg that he issued his "Lehrbuch der Mineralogie" (1st ed., 1886; 2d ed., 1904).

In the autumn of 1884 Professor Bauer transferred his activities to the University of Marburg, where he has been professor of mineralogy and petrography for the past thirty years. During this period he has devoted special attention to the diabases of Hesse and Nassau and to the basaltic region of Hesse, formations which theretofore had been little studied.

At the time of Professor Bauer's removal to Marburg, he succeeded to C. Klein as editor of the mineralogical section of the *Neues Jahrbuch für Mineralogie, Geologie und Paläontologie* and has carried on this task up to the present time. During this long period more than fifty regular volumes of the *Jahrbuch* and thirty-eight supplementary volumes have been issued, and also more than a dozen volumes of the *Centralblatt für Mineralogie, Geologie und Paläontologie*, a publication connected with the *Jahrbuch*, so that the editorial supervision of Professor Bauer has covered some one hundred volumes of these journals.

The valuable researches and publications of Professor Bauer on precious stones also belong to this period, visits to the famous gem-cutting establishments of Idar-Oberstein and to the diamond-cutters of Hanau having aroused his interest in this direction. A more definite direction to his activity was, however, provided by the plan of a German publishing house to bring out a translation of the present writer's "Gems and Precious Stones of North America." The task of translating and adapting this book was entrusted to Professor Bauer. As the publishers wished to enlarge the scope of the work while retaining its rich embellishment of colored plates, the enterprise resulted in the production of the "Edelsteinkunde" (1st ed., 1896; 2d ed., 1909), an English version of which was published by Dr. L. F.

Spencer, director of the mineralogical department of the British Museum, in 1904.

GEORGE F. KUNZ

Optic Projection. Principles, Installation and Use of the Magic Lantern, Projection Microscope, Reflecting Lantern and Moving Picture Machine. By SIMON HENRY GAGE and HENRY PHELPS GAGE. The Comstock Press, Ithaca. 1914. Pp. 731. \$3.00.

Professor Gage and his son, Dr. Gage, have written a timely and compendious treatment of optical projection that will be heartily welcomed by all who are interested in the subject. Such recent developments of the art of projection as cinematography and opaque projection are discussed at length, while the older ordinary forms of projection are not neglected.

The titles of the fifteen chapters are, in order: Magic Lantern with Direct Circuit; Magic Lantern with Alternating Current; Magic Lantern for Use on the House Electric Lighting System; Magic Lantern with the Lime Light; Magic Lantern with Petroleum Lamp, with Gas, Acetylene and Alcohol Lamps; Magic Lantern with Sunlight, Heliostats; Projection of Images of Opaque Objects; Preparation of Lantern Slides; The Projection Microscope; Drawing and Photography with Projection Apparatus; Moving Pictures; Projection Rooms and Screens; Electric Currents and their Measurement, Arc Lamps, Wiring and Control, Candle Power of Arc Lamps for Projection; Optics of Projection; Uses of Projection in Physics, Normal and Defective Vision. In addition there is given a historical outline of the origin and development of projection apparatus, a list of manufacturers of and dealers in projection apparatus, a bibliography and an index of both names and subjects. There are 413 cuts and diagrams.

The authors state that their aim has been to explain the underlying principles upon which the art of projection depends and to give such simple and explicit directions that any intelligent person can succeed in all the fields of projection. The point of view throughout is that of the skilled amateur. To the professional operator the treatment will appear academic, to the theorist it will appear very prac-

tical, but all will agree that it covers the middle ground clearly and exhaustively.

P. G. NUTTING

THE METEOROLOGY OF ADELIE LAND, ANTARCTICA

THE climatic facts set forth by Sir Douglas Mawson in his interesting volumes, "The Home of the Blizzard," reviewed last week in SCIENCE, justify his claim that it is the stormiest spot on the face of the earth. Although the data as to the weather are desultory and incomplete, except as to the winds, yet a brief survey of this newly discovered land is of scientific interest. Fortunately the expedition was equipped with recording instruments for barometer, sunshine, temperature, wind, etc., so that data exist for full and satisfactory discussion of local meteorology in the promised scientific volumes. Observations were made at the main base, Commonwealth Bay, 67° S., 133° E., and by the sledging parties through King George Land.

No table of monthly means of any kind are given, but it is stated that the mean temperature for the first year was slightly above zero. This is an exceedingly low temperature for the latitude, 67° S. It is, however, not a local cold of radiation, but a cold of translation through the continuous and violent downflow of air from the elevated plateaus of Antarctica, 11,000 feet or more above sea level. The sharp pitch of the land is shown by the rise of 1,900 feet in fourteen and a half miles from the sea. The temperatures were never exceeding low, but were steadily maintained. The minimum temperature at the seacoast was only -28°, and the lowest observed on the ice-cap of the hinterland during the spring sledging was -35°; on September 18, 1912.

From a shaft excavated in the nevé of the hinterland, at an elevation of 2,900 feet, Bage calculated that the mean temperature of the snow, which would be higher than the air, for the year was approximately -16°. It would not be unreasonable from these data to place the mean annual temperature of the south-polar plateau at -40°. The contrast between temperatures during high winds and in pe-

riods of comparative calm are noticeable. On November 19, during good weather, at an elevation of 2,600 feet the temperature fluctuated between zero and 18°, but five days later with a wind of 40 miles per hour it sank to -10°. On December 18, at 5,600 feet, the temperature rose with fine weather twenty-four degrees in a day, while the black bulb registered 105° in the sun.

Wild's station, Queen Mary Land, 66° 30' S., 95° E., about 1,200 miles to the westward of Mawson's on Adelie Land, appears from the few data available to be somewhat warmer, although the extremes were greater, a minimum of -38° being reported on December 21, 1912. The monthly mean temperature for June, 1912, was -14.5°, and for July -1.5°, while the means for the German expedition, under Drygalski, about 150 miles to the westward, in 66° 2' S., 89° 38' E., in 1902 were 0.5° for June, -0.6° for July, and for a year 11.3°. From these comparative data the annual mean at Wild's station, Queen Mary Land, would be about 8°. Field observations on the glacier-covered hinterland show a minimum of -47°, and a reading of 87° on December 21, from a thermometer laid on an area of black rock. These data probably give an approximation to the annual mean temperature of slightly above zero, Fahrenheit, along the antarctic circle for say 2,000 miles, between 86° and 150° E. longitude.

Bearing on the intimate local relations between the winds and the temperatures of Adelie Land, Mawson says:

The stronger the wind blew, the less variation did the thermometer show. Over a period of several days there might be a range of only four or five degrees. . . . The compression of the atmosphere during the gusts affected the air temperature so considerably that, coincident with their passages, the mercury column would be seen rising and falling through several degrees.

The only statement available as to the barometer reading runs:

On July 11, 1913, there was an exceptionally low barometer at 27.794 inches. At the same time the wind ran riot once more—298 miles in three hours. The barometric curve, remarkably even,

did not show as much range as one twentieth of an inch. The highest barometric reading was on September 3, 30.4 inches, and the comparison indicates a wide range for a station at sea-level. . . .

Annual barometric means in other portions of the Antarctic regions are as follows: *Discovery*, 77° 51' S., 167° E., 1902-04, 29.29 inches; Cape Adare, Victoria Land, 2 months only, 29.134; *Belgica*, 70° 30' S., 88° 30' W., 1902-03, 29.307; *Gauss*, 66° 2' S., 89° 38' E., 1902-03, 29.134. The data of Mawson's expedition will have a bearing on the theory quite steadily advanced, but which the writer has been inclined to question, of a marked anticyclonic area over the vicinity of the South Pole.

The extreme violence of the winds, and the general prevalence of drifting snow have made it impossible to measure with any degree of definiteness the snowfall of Adelie Land. Heavy falls of snow occurred, one being mentioned as amounting in a day to two feet. Of the effect of the wind on the snow Mawson says:

First, under the flail of the incessant wind, a crust would form, never strong enough to bear a man. Next day the crust would be etched, and small flakes and pellets would be carried away. Long shallow concavities would now be scooped out; these became deeper hour by hour, becoming at last the troughs between the crests of the snow-waves or sastrugi.

The abrasive effects of the drifting snow were astonishing. He adds:

The southern, windward faces of exposed rocks were on the whole smooth and rounded; the leeward faces were rougher and more disintegrated. On the windward side the harder portions of the non-homogeneous rocks were raised in relief.

Of quantities he says:

Day by day deluges of drift streamed by the Hut, at times so dense as to obscure objects three feet away, until it seemed as if the atmosphere were almost solid snow.

Mawson adds:

A point which struck me was the enormous amount of cold communicated to the sea by billions of tons of low-temperature snow thrown upon

its surface, the water already at the freezing point.

The most remarkable feature of the climatic conditions of Adelie Land are the violence and constancy of the winds. They are hurricane in force and, from the data in these volumes, appear to have come invariably from the south-south-east. Their regularity was most remarkable, and the direction so constant that field parties traveled during blizzards and in semi-darkness by shaping their course relative to the wind. Indeed the wind—and the sastrugi formed by it—was a far better direction-guide than was the compass, affected by their proximity to the magnetic pole. The average hourly velocity of the wind for the first year—determined by a registering Robinson anemometer, was fifty miles. The average for March, 1912, was 49; April, 51.5, and May, 60.7 miles. Hourly velocities of 90 miles were not uncommon, and in a number of cases the rate exceeded 100 miles. The most remarkable winds—which from the snow carried by them assumed the character of blizzards—are as follows: 1912 (for the 24 hours), May 11, 80 miles; May 15, 90; May 22 (gust approximating 200 miles per hour, with temperature of -28°); 1913, May, 17 (24 hours), 83 miles; May 18, 93.7 (between 6 and 7 P.M. of the 18th the instrument recorded 103 miles); July 5, 116 miles in one hour, and an average of 107 miles for eight consecutive hours; July 11, 298 miles in three hours; August 16, 105 miles in an hour. Gusts were determined from time to time by an instrument called a puffometer, by which winds in gust were noted of an extreme velocity of about 220 miles, though necessarily such record could not be considered as absolutely accurate.

Meteorologists have usually associated whirlwinds with heated or desert regions. Mawson related:

Whirlwinds of a few yards to a hundred yards or more in diameter which were peculiar to the country. The velocity of the wind in the rotating column being very great, a corresponding lifting power was imparted to it. The lid of a case, weighing more than 300 pounds, was whirled into the air and dropped fifty yards away. An hour afterwards the lid was picked up again, and

struck against the rocks with such force that part of it was shivered to pieces.

Regions of calms sometimes obtained in a sheltered locality immediately under hurricane winds. One man working in a fifty mile gale at the Hut, on the upper cliffs, walked down to the harbor ice and suddenly found himself in an area of calm. As compared with the force of winds of the *Discovery*, $77^{\circ} 51' S.$, $167^{\circ} E.$, 10.3 miles per hour, the winds of Adelie Land are nearly six times as violent. As to direction the *Discovery* winds as determined from the lower clouds showed 18 per cent. S., 15 S.W. and 15 S.E. At Cape Adare, with 10 per cent. calms, there were 20.4 per cent. winds from the S.E. and 13.9 from the S. These data seem to bring the S.S.E. winds of Adelie Land in harmony with those a few hundred miles to the southeast. The *Gauss*, $66^{\circ} S.$, $90^{\circ} E.$, was frozen-in a long distance from land so that its winds, 47.8 per cent. from the E., are not directly comparable with those 1,700 to 2,000 miles to the eastward.

It is evident that Mawson is justified in calling Adelie Land the *Home of the Blizzard*, and in claiming that it is the windiest region on the earth at the level of the sea. Meteorologists will look forward with interest to the publication of the full observations with their scientific discussion.

A. W. GREELY

REPORT OF THE COMMITTEE OF THE
AMERICAN ASSOCIATION OF ANATOMISTS ON PREMEDICAL WORK
IN BIOLOGY

At the meeting of the American Association of Anatomists in Philadelphia, December, 1913, a committee was named by the president of the association to confer with the zoologists on the subject of work in biology preliminary to the study of medicine.

In accordance with the original motion of the chairman, which led to the appointment of this committee, the following report was submitted to the association December 29, 1914, at the St. Louis meeting:

Your committee was appointed to confer with the zoologists to ascertain what coopera-

tion may be expected toward standardizing work in biology required of students looking forward to the study of medicine; and to formulate the considerations which would seem practical to incorporate in plans for such courses.

The Zoological Society promptly appointed a committee for this conference, and the following questions were discussed, not only with this committee, but with a number of representative members of the Zoological Society. Besides this, published statements of courses and of discussions on this subject were examined.

The following questions seemed to be most important.

Question 1. Is the work given in different colleges in the elementary, general course in biology adapted to satisfy the requirements of premedical training in this subject?

Question 2. Is it possible to so select and standardize the work of the first year in biology in different colleges as to make it uniform, and to include, here, all needed to make it an adequate course?

Question 3. If an ideal course, including sufficient preliminary work, can not be secured within the one-year period advocated, what principles should be urged to govern the planning of the biological work of students looking forward to the study of medicine, so that they will profit most by the training of the first year, and be best prepared to follow this up in special departments of biology more directly related to medicine.

Question 4. What additional work is to be advised, which is not to be obtained in the first year's general course?

Both committees agree that it is of the first importance to urge the selection of only thoroughly trained scientific men as teachers for this work. Such men can be trusted to insist on real scientific methods and to select the best material and treatment to give the beginner a practical introduction and basis for further work.

Beyond this point, however, the committees were unable to proceed. The zoologists suggested that the anatomists should draw up a statement of what they desire the zoologists

to do, in preparing students for anatomy. After this has been done, the zoologists are ready to consider how far it is practicable to meet these needs. Several attempts have been made in this direction, and your committee submits the following statement to the association for its approval, and transmission to the zoologists.

At the present time a one-year's course in biology is generally required as a preparation for the work of the medical school. This study of biology must serve as a preparation for medical work in physiology, pathology, bacteriology and parasitology, as well as anatomy, and it may fairly be questioned whether a single college course is adequate for this purpose. The study of botany alone is obviously insufficient, and the domain of zoology is so vast that much care should be exercised in the choice of those phases of the science to be presented to young students. Courses which are primarily experimental and deal with the functions and reactions of animals, although excellent in preparation for the physiological work of the medical school, are not the proper basis for the study of human anatomy. It is the purpose of this report to point out only those features of the college preparation which experience has shown to be desirable, and in fact essential, for the successful study of gross and microscopic anatomy.

No uniform or stereotyped preparatory course is recommended, for it is recognized that every teacher should give special attention to those subjects and groups in which he is particularly interested, and to the knowledge of which he has contributed by his own researches. Success depends in large part upon the ability of the teacher, but the following purposes of instruction should not be forgotten if the preparatory work is to satisfy the requirements of anatomy.

1. Students frequently begin the study of human anatomy with an insufficient knowledge of the lower forms of animal life. The broad knowledge of the various classes of animals and of invertebrate and lower-vertebrate morphology, which was the inspiration of the

great anatomists of the past, is now too often replaced by vague considerations of the method of science and ideals of observation. A return to the study of animals, as objects of interest in themselves, apart from theoretical considerations and possible relations to human society, is therefore recommended. The student should obtain a synoptic knowledge of the animal kingdom, and should be able to classify, in a general way, and to describe the life histories of the common forms of animals, aquatic and terrestrial, which may be collected in his locality. A beginning in such work may well be made by the student independently or perhaps in high-school courses, but such fragmentary and elementary studies should be supplemented by a thorough college course. The first-hand familiarity with animals should serve as the basis for all further work.

2. As a result of the knowledge of genera and species which the student should have obtained directly for himself by studying some group of animals or plants, questions of the origin of species and of the relation of the great classes of animals to one another are inevitably before him as philosophical problems. Collateral reading then becomes as necessary for the biologist as for the man of learning in any other branch of knowledge. Selected works of Lamarck, Darwin, Huxley, Mendel and others should be freely consulted. This literature, which in its influence upon human thought has far outspread the bounds of biology, should not be neglected by the student of zoology, whose particular heritage it is. Since the idea that science can not be read, and that there is no knowledge in books, is often taught as a cardinal principle, it has come about that students of zoology have little knowledge of, or respect for, the writings of the makers of their science.

3. Before beginning the study of human histology, every student may reasonably be expected to be familiar with the use of the microscope and with the simpler methods of preparing specimens for microscopic examination. This technique can be learned in connection with various courses, perhaps the

most useful of which is a general study of the cell with a comparative study of the elementary tissues. The maturation of the germ cells and the processes of fertilization and segmentation can not be properly presented in the medical curriculum, and these fundamental biological phenomena should therefore be observed in college courses. The development of the chick, which was studied primarily by physicians to explain the growth of the human embryo, can likewise receive little attention in the medical school. These subjects are all very desirable in themselves, and if studied by laboratory methods, will supply the requisite skill in the use of the microscope.

4. In preparing for human dissection, comparative anatomy should be studied with the same standards of thoroughness which obtain in the dissecting room. The student should learn to dissect rapidly and well, and to record with careful drawings and brief descriptions the forms and relations of the structures which he has disclosed. But such studies are not useful merely for their methods. A knowledge of comparative anatomy, including especially the anatomy of the lower vertebrates, is indispensable for understanding the structure of the human body. For other reasons also, human anatomy must be treated as an advanced study. The state does not provide bodies for dissection in order that untrained students may learn from them those elementary facts, which may be understood equally well by dissecting cats or rabbits. "It is absurd," says President Eliot, "to begin with the human body the practise of dissection." And the value of dissection is so great in relation to both medicine and surgery, that an adequate preparation should be required. For the study of anatomy, in the words of Lord Macaulay, "is not a mere question of science; it is not the unprofitable exercise of an ingenious mind; it is a question between health and sickness, between ease and torment, between life and death."

5. Finally, these recommendations may be summarized as a plea for a more thorough study of zoology on the part of those planning

to enter the medical schools. The zoological courses should not be abridged and popularized in order that time may be saved for other pursuits, or that the science may seem more attractive to college youth. Courses in anatomy and physiology which duplicate the work of the medical school, and courses in "medical zoology," ought not to be substituted for the strictly zoological university courses. The science of zoology is of such great service to students of medicine that it deserves a large place in their undergraduate studies. With medical anatomy, it constitutes "a subject essentially one and indivisible"; and the penalty for its neglect is inadequate preparation for medical practise.

Committee: H. McE. KNOWER, *Chairman*,
F. T. LEWIS,
W. H. LEWIS

ST. LOUIS, MISSOURI,
December 29, 1914

In the following summary, the chairman of the committee has rearranged the main points of the above report in groups, to correspond to the four questions proposed at the beginning; so that a more definite idea may be secured of the manner in which these are answered. In assembling the answers to the different questions the exact sense of the report itself has been retained. In answering questions 3 and 4 an effort has been made to indicate what we may reasonably expect to include in the first year, and what should be advised in addition.

I and II. The first two questions formulated by the committee are answered in the negative; that is, a one-year's course is not regarded as sufficient, and a uniform, standardized course seems undesirable. An introduction to the subject through special courses in selected "medical zoology" is also disapproved.

III. (a) In regard to the third question; it has seemed necessary to urge a more thorough knowledge of the morphology of lower forms of animals and their life histories. While the anatomists in adopting this statement as given in the report, undoubtedly expect the physiological aspects of these mechanisms to be con-

sidered as necessary accompaniments of such first-hand familiarity with animals, it is urged in the report that the introductory college course shall not be "primarily physiological." It is earnestly desired that the work shall involve a rigorous grounding in comparative morphology, especially of lower forms, which furnishes not only the best basis for human anatomy, but is a very essential preliminary for comparative and human physiology.

(b) It is urged that the theoretical and philosophical considerations which accompany the course shall follow a practical acquaintance with animals, rather than that special animal structures shall serve chiefly as illustrative material for lectures on general biological theories, with a neglect of a thorough study of a series of animal forms.

(c) The additional principles which should govern the planning of the introductory courses, beyond those just stated, are:

The selection of suitable teachers.

The undesirability of attempting to establish a uniform preparatory course, or courses especially limited to applications to medicine.

The acquirement of skill in the use of the microscope, and of correct scientific method of work in connection with the work of the course.

The beginnings of embryology and cytology.

IV. As to the last question, number 4, the report does not attempt to decide what proportion of the recommended preparation for anatomy can be obtained by a student in the first year's course. This must be indicated by the zoologists. It seems evident to a student of present conditions, however, that most of the work desired in cytology and comparative, general histology; comparative anatomy of vertebrates; or systematic zoology will have to be elected by students looking forward to medicine, after they have taken the introductory course. It is to be hoped that the elements of vertebrate embryology will be included in that course. Some of this work may well be done in one of the excellent summer laboratories.

V. Finally, the importance of collateral reading in the masterpieces of biological literature is strongly emphasized.

At the St. Louis meeting of the American Association of Anatomists, December 29, 1914, the report of the committee on premedical work in biology was approved by the association; and the committee was continued with instructions to submit the approved report to the zoologists, and to secure their cooperation in carrying the work further.

H. MCE. KNOWER, *Chairman*

SPECIAL ARTICLES

SEX DETERMINATION AND SEX CONTROL IN GUINEA-PIGS

THE observations, a short exposition of which is given here, were made on guinea-pigs, being used by Professor Stockard in heredity experiments. He very kindly placed the material at my disposal for this study, and I wish to express my appreciation of this favor.

These observations show that the sex of a guinea-pig is determined sometimes by two and sometimes by three factors, depending upon whether the mother has previously born young.

The first factor "A" is the sex tendency of the father. If the father has a male sex tendency, his sons will have a female tendency and his daughters a male tendency. If, on the contrary, the father possesses a female tendency, his sons will have male tendencies and his daughters female tendencies. In other words, sons exhibit the opposite and the daughters the same tendency as the father.

The second factor "B" is the sex tendency of the mother. A mother with a male tendency gives her daughters a female and her sons a male tendency. The mother with a female tendency gives her daughters a male and her sons a female tendency. Thus the transmission of the sex tendency from the female is also criss-cross in the same fashion as that of the male. The females inherit like tendencies from their father and the males like

tendencies from their mother, whereas the males inherit the reverse tendency of their father and the females the reverse tendency of their mother.

The third factor "C" is confined to the female and is a change of sex tendency from litter to litter. This change in tendency manifests itself in the following way:

If the first litter contains only males, the mother acquires a female tendency for the next litter and vice-versa. This new tendency varies in strength, depending upon the number of young of one sex contained in a litter. The greater the number of males in a litter, the stronger the female tendency will be for the next litter. This tendency is still more emphasized if the mother is successively mated with males of a definite tendency, and therefore forced to produce more and more young of one sex.

The tendency of the various animals of a certain stock must first be ascertained in an experimental manner; given a number of undetermined males and females, each male must be mated with all the females and each female with all the males. After all the animals have been tested in this way, the results will show more males from some animals and more females from others. If, now, the offspring from these matings be grouped so as to take those animals which have come from more male producing fathers and their tendency be tested, it will be found that from the males more females will be produced and from the females more males. Provided the determination of the sex tendency for the first set of animals was absolutely correct, and if there was no other factor in action, the proportion of males to females should be as 75:25 from male producing males mated with females having different tendencies, and from female producing males the proportion is reversed. It is, however, very difficult to determine absolutely the sex tendency of an animal after only a few matings, and for this reason, some animals supposed to have a male tendency will probably have a weak female tendency, and *vice versa*.

In order to find with reasonable definiteness

the tendency of animals, the tendency of the ancestors for three or more generations should be known. It must also be recalled, as explained above, that the third factor "C" in the female reduces the difference between the ratio numbers of her male and female descendants. As a result of this, the difference between the number of males and females considering only mother tendency is smaller than the difference between males and females in the light of only the father tendency. A male has a male tendency or a female tendency and always maintains it, whereas the female has a born male or female tendency, but in addition to this she has a second tendency to change her sex tendency from litter to litter. The number of males and females derived from the second generation was as follows:

I. Descendants of males whose fathers had a male tendency mated with mixed females; 39 males to 54 females, *i. e.*, 41.04 per cent. males to 58.06 per cent. females (sex ratio 72.20).

II. Descendants of males whose fathers had a female tendency mated with mixed females; 42 males to 23 females, *i. e.*, 64.61 per cent. males to 35.39 per cent. females (sex ratio 182.60).

III. Descendants of males whose mothers had a male tendency mated with mixed females; 64 males to 53 females, *i. e.*, 54.70 per cent. males to 45.30 per cent. females (sex ratio 120.83).

IV. Descendants of males whose mothers had a female tendency mated with mixed females; 12 males to 13 females, *i. e.*, 48 per cent. males to 52 per cent. females (sex ratio 92.30).

V. Descendants of females whose mothers had a male tendency mated with mixed males; 13 males to 18 females, *i. e.*, 41.94 per cent. males to 58.06 per cent. females (sex ratio 72.22).

VI. Descendants of females whose mothers had a female tendency mated with mixed males; 51 males to 43 females, *i. e.*, 54.25 per cent. males to 45.75 per cent. females (sex ratio 118.60).

VII. Descendants of females whose fathers had a male tendency mated with mixed males; 38 males to 36 females, *i. e.*, 51.38 per cent. males to 48.62 per cent. females (sex ratio 105.55).

VIII. Descendants of females whose fathers had a female tendency mated with mixed males; 33 males to 37 females, *i. e.*, 47.15 per cent. males to 52.85 per cent. females (sex ratio 89.18).

These figures show that in the sons the tendency received from the father is stronger than that coming from the mother, while in the daughters the opposite is true.

When one examines the descendants of animals whose fathers had a male tendency and mothers a female tendency, a higher difference in the relative number of males and females is found than from those cases in which the fathers alone had a male tendency. Twenty descendants of such male animals (father male tendency and mother female tendency) mated with mixed females consisted of four males and sixteen females, *i. e.*, 20 per cent. males and 80 per cent. females (sex ratio 25.00). From the females of the same type (father male tendency and mother female tendency) mated with mixed males, 29 males and 15 females were derived, *i. e.*, 65.90 per cent. males to 34.10 per cent. females (sex ratio 193.33).

From the second-generation males whose fathers had a female tendency and whose mothers show a male tendency when mated with mixed females were derived 32 males and 15 females, *i. e.*, 68.08 per cent. males to 31.92 per cent. females (sex ratio 213.83). From the females of the same type (father female tendency and mother male tendency) mated with mixed males were derived 6 males and 13 female descendants, *i. e.*, 31.58 per cent. males to 68.42 per cent. females (sex ratio 46.15).

Should one select males whose fathers had a female tendency and whose mothers had a male tendency and mate these with females whose fathers had a male tendency and whose mothers had a female tendency, a higher difference in the relative number of males and

females will be found in their descendants than in any other possible case. From such combinations were derived nine animals, all males. In the same way, from the combination a male derived from a father, male tendency, and mother, female tendency, mated with a female from father, female tendency and mother male tendency, were derived six animals all of which were females.

This regulation in the inheritance of the sex tendency is especially interesting in affording an explanation of the manner in which the equilibrium is maintained between the number of male and female offspring of a given species. With each new generation each male animal has an opposite tendency from that of his father and each female animal an opposite tendency from that of her mother. It, therefore, follows that a disturbance of the equilibrium in one generation will tend to be restored by the opposite tendencies in the following generation. The above-mentioned change of sex tendency from litter to litter in the female leads to the same result. This third factor "C" regulates equilibrium from birth to birth so that any disturbance of a great degree is impossible.

The difference in the proportion between the sexes in different species may be due to the fact that in some species the father and mother have an equal influence on the determination of the sex of their offspring while in other species either the father or the mother may have the greater influence.

When father and mother have equal influence, the combination father, male tendency, with mother, female tendency, will give equal number males with females tendencies and females with male tendency, and the combination father, female tendency, with mother, male tendency, will give equal number males with male tendency and females with female tendency. In this way equal numbers of male and female descendants will be produced and equal numbers of the descendants will have male and female tendencies. In such a case the sex ratio should be 100 per cent. Should, on the other hand, the mother have the greater influence on the determina-

tion of sex, as seems to be the case in the guinea-pigs, then the number of descendants with a male tendency will be greater than the number of those having a female tendency, as the following scheme shows:

Father with male tendency mated with mother with female tendency will give more females (male tendency) than males (female tendency).

Father with a female tendency mated with a mother with a male tendency gives more males (male tendency) than females (female tendency). Therefore from either combination the greater number of offspring have a male tendency and as a result of this the sex ratio will be greater than 100.

In guinea-pigs it really seems that the influence of the mother is greater than that of the father, and this may be the explanation of the fact that the number of male guinea-pigs is greater than the number of females.

Finally, if the father has a greater influence on sex determination than the mother the number of descendants with a female tendency will be greater than the number with a male tendency, and consequently the sex ratio will be smaller than 100, as is shown by the following analysis:

Father with male tendency mated with mother with female tendency gives more males (female tendency) than females (male tendency). The father with female tendency mated with mother with male tendency gives more females (female tendency) than males (male tendency). Thus from either combination the greater number of offspring have a female-producing tendency and as a result of this the sex ratio will be less than 100.

Concerning the third factor, "C," the change of the sex tendency from litter to litter, a statistical examination shows the following results:

First: Relative number of male and female descendants after the birth of one or more females in one litter; 38 males to 12 females, i. e., 76 per cent. males to 24 per cent. females (sex ratio 316.66).

Second: Relative number of male and female descendants after birth of one or more

males; 13 males to 38 females, i. e., 25.49 per cent. males to 74.51 per cent. females (sex ratio 34.21).

To determine further whether the sex-tendency of males showed any inclination to change from mating to mating the records were counted in the following manner:

Taking the matings of given males following matings that produced only female young, it was found that the product of such matings consisted of 22 males to 27 females, i. e., 44.90 per cent. males to 55.10 per cent. females (sex ratio 81.48).

Taking the matings of given males following matings that produced only male young, it was found that the product of such matings consisted of 28 males to 24 females, i. e., 53.84 per cent. males to 46.16 per cent. females (sex ratio 116.66).

This result is therefore the reverse of that shown by the females. Whereas the females show an opposite tendency following each litter, the males always maintain the same tendency.

Only those litters which were purely male or female were used in the above consideration. After a mixed litter of males and females, which is more common under natural conditions, there is not a pure, but also a mixed sex tendency. This fact renders the recognition of the "O" factor extremely difficult.

Such a characteristic change in tendency from birth to birth also seems to occur in other animals. The daphnids, for instance, seem to have some such regulation very definitely expressed.¹ In these organisms also the sex tendency changes from generation to generation as well as from birth to birth in such a way that not after each generation and each birth, but after a number of generations and births, differing with different species, the exclusive production of parthenogenetic female ceases and the first males appear. Doubtless we have in this an example of a change of the sex tendency, but its expression is quite different from that in the guinea-pigs.

From a theoretical standpoint, it is very important that coincidentally with the change of sex tendency in the summer eggs from female to male in *Moina rectirostris* var. *Lilljeborgii*, there is also a change in the color of these eggs from violet to blue.² This fact probably indicates that some chemical change occurs in the eggs at the same time that the change in the sex tendency takes place.

At the present time I am endeavoring to complete my observations and to determine statistically the relative value of the three factors in different combinations. Since, however, the animals at my disposal are designed especially for the study of the degenerative influence of alcohol, it will, no doubt, require a long period of time to collect hundreds of selected cases, since so few animals of the generations later than the third are capable of reproduction.

This preliminary report is published with the hope that other investigators, having a large stock of different animals at their disposal, may further contribute to the solution of this problem in all its details.

GEORGE PAPANICOLAOU

DEPARTMENT OF ANATOMY,
CORNELL UNIVERSITY MEDICAL COLLEGE

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

SECTION C

The first session was held on the afternoon of Thursday, December 31, at the John Harrison Laboratory of Chemistry, Vice-president Edgar F. Smith in the chair, with an attendance of about 75. The following officers were elected:

Vice-president—William McPherson, Ohio State University.

Member of Council—W. T. Taggart, University of Pennsylvania.

Member of General Committee—L. W. Jones, University of Cincinnati.

Member of Sectional Committee—E. C. Franklin, Stanford University.

The section passed a resolution to the following effect: That the committee of Section C endeavor

¹ Papanicolaou, G., "Experimentelle Untersuchungen über die Fortpflanzungsverhältnisse der Daphniden," *Biol. Zentralbl.*, 30, 1910.

² Ibid.

to arrange its program so as to center round some definite topic or group of topics, the choice and treatment of which should preferably be such that they prove interesting and useful, even to any one not especially conversant with chemistry; and that Section C favors the relegation to the Chemical Society of unrelated papers of interest only to chemists, though this would in no wise preclude the holding of joint meetings with a local section of the Chemical Society or with any other society.

The following papers were read:

The Densities and Degrees of Dissociation of the Saturated Vapors of the Ammonium Halides:
ALEXANDER SMITH and ROBERT H. LOMBARD.

The Entropy of Vaporization of Normal Liquids:
J. H. HILDEBRAND.

A discussion of the value of the quotient Q/T (Q is the latent heat, T the temperature, of vaporization) and of its variations.

Chemical Preservation of Manure: P. A. MAIGNEN.

A plea for the better conservation of the valuable material at present going largely to waste as sewage.

A Rapid Lime Requirement Method for Soils without the Use of a Factor: THOS. F. MANNS.

A description of the method, illustrated by examples of the results attained.

On the Universal Application of the Molecular Theory. A Question: H. E. MORROW.

Suggests the possibility of dispensing with the conception of molecules in the case of complex colloids, such as proteins; that a conception of continuous atomic linkings serves to account for some of the properties which such complex substances exhibit.

On the forenoon of January 1, in the laboratory of hygiene of the University of Pennsylvania, Section C held a joint session with Section K and with the Society of American Bacteriologists, devoted to a symposium on "The Lower Organisms in Relation to Man's Welfare." The attendance was about 200. The list of speakers and titles follows; the papers will be published in full later.

Theories of Fermentation: C. L. ALBRECHT.

The general mechanism of the action of fermentations.

Enzyme Action: C. S. HUDSON.

A discussion of the chemical changes involved in the action of enzymes.

Role of Microorganisms in the Intestinal Canal: A. I. KENDALL.

¹ See *J. Am. Chem. Soc.*, 37: 38, 1915.

Microorganisms in their Application to Agriculture: C. E. MARSHALL. JOHN JOHNSTON,
Secretary of Section C

THE FEDERATION OF AMERICAN SOCIETIES FOR EXPERIMENTAL BIOLOGY

THE second annual meeting of the Federation, comprising the American Physiological Society, the American Society of Biological Chemists, the American Society for Pharmacology and Experimental Therapeutics, and the American Society for Experimental Pathology, was held at St. Louis on December 28, 29 and 30, 1914, in the laboratories of the Washington University Medical School.

Three joint sessions of all of the above societies were held at which twenty-eight communications were presented. The titles of these papers have already appeared in the account of the meetings of the Physiological Society.¹

At the first session the following memorial addresses were delivered:

"S. Weir Mitchell," by E. T. Reichert, read by W. B. Cannon.

"C. S. Minot," by F. S. Lee.

The following resolution was presented and unanimously adopted:

WHEREAS, various of the European nations with which many of our members are related by birth, descent or intellectual friendship are now at war, Resolved, that we extend to the scientific men within these nations the hope of an early and enduring peace, which will leave the nations with no permanent cause of rancor towards each other, and which will insure to each the glories of scientific and humanitarian achievement in accordance with its own conception of these ideals.

Printed copies of this resolution, suitable for mailing, have been prepared and may be obtained from Professor Graham Lusk, Cornell Medical College, New York City. It is hoped that members of the Federation will send such copies with their compliments to their scientific friends in the countries now at war.

Executive Committee for the Year 1915.—Chairman, Torald Sollmann; Secretary, John Auer, for the Pharmacological Society; W. B. Cannon, C. W. Greene, the Physiological Society; Walter Jones, P. A. Shaffer, the Biochemical Society; Theobald Smith, Peyton Rous, the Pathological Society.

THE AMERICAN SOCIETY OF BIOLOGICAL CHEMISTS

THE ninth annual meeting of the society was held at St. Louis on December 28, 29, 30, 1914, in the laboratories of the Washington University Medical School. Three joint sessions were held with the other societies composing the federation in addition to two sessions conducted independently.

The following communications were presented at the independent sessions of the society and from this society at the joint sessions. The titles of other papers which were presented from the other societies at the joint sessions have been given in the account of the meetings of the Physiological Society.¹

"The Influence of Food on Metabolism," presidential address, by Graham Lusk.

"The Excretion of Creatine During Fasting," by F. D. Zeman (by invitation) and P. E. Howe.

"The Determination of Creatine and Creatinine in Urine; and the Occurrence of Creatine," by J. L. Morris (by invitation).

"A Method for Determining and Comparing the Local Toxicity of Chemical Compounds," by H. J. Corper.

"Experiments with Pure d-l-Glyceric Aldehyde," by R. T. Woodyatt.

"The Level of Sugar in the Blood Flowing from the Liver under Laboratory Conditions," by J. J. R. Macleod and R. G. Pearce.

"The Level of Blood-sugar in the Dog," by P. A. Shaffer and R. S. Hubbard (by invitation).

"A Method for the Decomposition of the Proteins of the Thyroid with a Description of Certain Constituents," by E. C. Kendall.

"Variations in Factors Associated with Acidity of Human Urine During a Seven-day Fast and During the Subsequent Non-protein and Normal Feeding Periods," by F. D. Zeman (by invitation), Jerome Kohn (by invitation) and P. E. Howe.

"The Mechanism of the Toxicity of Halogen Narcotics," by E. A. Graham (by invitation).

"On the Relation of the Oxygen Tension of the Atmosphere to Combustion," by H. C. Dollwig (by invitation), A. C. Kolls (by invitation) and A. S. Loevenhart.

"The Influence of Sodium Carbonate on the Glycosuria, Hyperglycemia and the Respiratory Metabolism of Depancreatized Dogs," by J. R. Murlin and B. Kramer (by invitation).

"The Possibility that Some of the Hepatic Gly-

cogen May Become Converted into other Substances than Dextrose," by J. J. R. Macleod.

"Narcotics in Phlorhizin Diabetes," by R. T. Woodyatt.

"Some Studies in Autolysis," by H. C. Bradley.

"On the Nature of the Hepatic Fatty Infiltration in Late Pregnancy and Early Lactation," by V. H. Mottram (by invitation).

"The Synthesis of Hippuric Acid in Experimental Tartrate Nephritis in the Rabbit," by F. B. Kingsbury (by invitation) and E. T. Bell (by invitation).

"The Determination of Blood Sugar" (demonstration), by P. A. Shaffer.

New Members—Olaf Bergeim, Jefferson Medical College, Philadelphia, Pa.; Alex. T. Cameron, University of Manitoba, Winnipeg, Canada; G. H. A. Clowes, Gratiwick Laboratory, Buffalo, N. Y.; B. M. Duggar, Missouri Botanical Garden, St. Louis, Mo.; Cyrus H. Fiske, Harvard Medical School, Boston, Mass.; R. A. Hall, University of Minnesota, Minneapolis, Minn.; C. G. Imrie, University of Toronto, Toronto, Canada; Benjamin Kramer, State University of Iowa, Iowa City, Ia.; A. Bruce Macallum, University of Toronto, Toronto, Canada; J. F. McClelland, University of Minnesota, Minneapolis, Minn.; J. Lucien Morris, Washington University Medical School, St. Louis, Mo.; Max Morse, University of Wisconsin, Madison, Wis.; V. H. Mottram, McGill University, Montreal, Canada; C. F. Nelson, University of Kansas, Lawrence, Kansas; E. L. Ross, Northwestern University Medical School, Chicago, Ill.; E. C. Shorey, U. S. Department of Agriculture, Washington, D. C.

Officers Elected—The following officers were elected for the year 1915:

President—Walter Jones.

Vice-president—Carl L. Alsberg.

Secretary—P. A. Shaffer.

Treasurer—D. D. Van Slyke.

Additional Members of the Council—Otto Folin, Graham Lusk, L. B. Mendel.

Nominating Committee—J. J. Abel, S. R. Benedict, H. D. Dakin, P. B. Hawk, J. J. R. Macleod, E. V. McCollum, V. C. Myers, T. B. Osborne, A. N. Richards.

Abstracts of the papers presented will be published in the *Journal of Biological Chemistry*.

THE CLASSIFICATION OF NERVOUS REACTIONS¹

It is within the memory of most of us what a distinct advance was made in the definiteness of our thinking about nervous reactions when the introduction and improvement of the Golgi method led up to the conception of the neurone doctrine. Previous to that time our mental picture of the reflex mechanism was not essentially incorrect; but its conception of the nature of the connection between the sensory fiber and the motor nerve cell was indefinite. When the new histological method revealed the posterior root fibers entering the cord and by means of collaterals ending in the immediate neighborhood of motor cells, there was revealed an almost diagrammatic mechanism which explained many reflex phenomena; and we can recall the enthusiasm with which all proceeded to construct combinations of neurones to serve as the anatomical basis of the various known functions of the nervous system; indeed, we have been engaged in this fascinating pastime ever since.

This is exactly as it should be, for only in this way could the possibilities of the new discovery be tried out. There is danger, however, in anything which is attractively definite; sometimes because it may belong among those things which are "too good to be true"; but more frequently because its successful explanation of many of the phenomena with which it deals may blind us to its failure to explain others;

¹Address of the chairman and vice-president of Section K (Physiology and Experimental Medicine), American Association for the Advancement of Science, Philadelphia, December 31, 1914.

and I think there are to-day, even among those who do not follow Apathy and Bethe in their indiscriminating attacks on the neurone theory, many who are seriously asking whether the neurone conception of the reflex exhausts the possibilities or nervous mechanisms.

For, after all, the distinct service of the neurone theory is its explanation of the mechanism of reflex action. It gives us a satisfactory explanation of simple and even of highly coordinated reflexes; but there are still left problems upon which its staunchest defenders will not claim that it throws much light. The contribution, for example, of the cerebellum to the execution of volitional or reflex actions is not self-evident in terms of the theory; the mechanisms of reinforcement and facilitation (*Bahnung*) are no more easily pictured now than before; and, above all, the whole field of cerebral physiology may be said still to be in the same state as was that of reflex action before Golgi made that fortunate mistake of putting some pieces of spinal cord which had been hardened in Müller's fluid into silver nitrate and beheld for the first time a nerve cell in all its glory.

The diagrammatic clearness of the picture of the reflex mechanism thus revealed has contributed largely to our present mental approach to the problems of neurology, an approach which is faithfully reflected in our text-book presentations of the subject. The first text-book chapter is largely anatomical, chiefly histological; the next chapter deals with reflex action which is presented to the student as par excellence the typical nervous action; the treatment of the subject then proceeds from the simpler reflexes to those requiring a higher degree of coordination; accustomed movements, such as those of locomotion, receive their explanation as an endless chain of

reflexes requiring for its operation the structures of the mid- and 'tween brains; finally the attempt to explain everything in terms of reflex action is carried into the field of cerebral physiology. With what success? One has only to read the text-books to find out. Some things, especially localization, are dwelt upon at length; the possibilities of excessively complex coordinations are suggested by the anatomical structure; but we miss entirely the satisfaction of seeing the cerebral functions clearly pictured in terms of neurone structure. We trace the "way in" and the "way out"; we see that the connection between the afferent and efferent nerve fibers is in the cortex; but what takes place in the cortex? Is it objectively nothing more than our typical reflex raised to the *n*th power of complexity? Perhaps it is; but does any one feel reasonably sure of it? For one, I confess I do not.

However that may be—and I have no intention of discussing the question—this much may certainly be said. We know that there are nervous actions which are not reflexes at all; furthermore, there are nervous actions which usually pass as reflexes, although they present striking and perhaps fundamental points of difference from the typical reflex arc of our neurone theory. The justification of these statements will be attempted in what follows. My present purpose and indeed the purpose of this paper is to challenge the wisdom of making the reflex arc the type of all nervous action either in our own thinking or in the presentation of the subject to students, and to suggest that we would act more wisely to cultivate a more open state of mind with regard to the existence of other possibilities.

This may be done, it seems to me, by drawing sharply the distinction at the outset between the following classes of nervous

action: automatic, axon reflex, unconditioned reflex, conditioned reflex and volitional. It is not claimed that this list is exhaustive. The physiology of such mechanisms, for example, as the plexus of Auerbach is at present too little understood to admit of successful classification. It is only claimed that the above are distinct forms of nervous activity; that they are carried out by different mechanisms, and that, as such, they should be given coordinate rank in the student's mind.

In the following discussion I shall not include any treatment of volitional action. I am concerned only with the proper classification of nervous actions and see no reason for changing the all but universal custom of placing volitional actions in a class by themselves. I shall, however, dwell at some length upon the automatic action, the axon reflex, and then discuss together the conditioned and the unconditioned reflex.

AUTOMATIC ACTIONS

In general an automatic action is one which originates in the mechanism involved and is not caused by any external influence acting only at the time of its occurrence. The ticking of a clock is an example. In the field of physiology we think at once of the beat of the heart, although other no less striking examples are known; a strip of the muscular coat of the stomach or intestine shows automatic contractions; and many of the processes of embryological development probably belong in the same category. Contrasted with these are skeletal muscles and many glands which become functionally active only in response to some sort of external stimulus, usually a nerve impulse.

Even in the case of the skeletal muscle, however, the external stimulus seems to act by causing the accumulation, and prob-

ably the localized accumulation of some physical or chemical condition within the cell leading to the discharge of energy. Thus an attractive theory of electrical stimulation of skeletal muscle supposes that certain semipermeable membranes within the muscle fiber are more permeable to ions of one electrical charge than to those of the opposite charge; hence in the migration of the charges to the two electrodes during the passage of a current there results an accumulation of electric charges at these membranes; and when this has gone on to a certain extent, the electrical condition thus created explodes an unstable fuel substance, energy is liberated and contraction results. The passage of the stimulating current has merely produced the accumulation of what may be called the "discharging conditions" within the cell.

In the automatic action these discharging conditions seem to accumulate without external assistance, possibly as the result of certain metabolic processes in the cell itself. External conditions, such as temperature, may influence the rate or the amount of discharge; but this does not make these external conditions stimuli in any true sense. Furthermore, we may speak, if we will, of the whole chain of events leading to the accumulation of the discharging conditions as an "inner stimulus"; but this would seem to involve an unnecessary and even questionable extension of the term stimulus.

An automatic nervous action is frequently defined as a discharge from a nerve cell caused by some other external stimulus than that of an exciting neurone; but, if the cell is discharged by an external stimulus of any kind, the action is not automatic. What we observe in such cases is activity, apparently, at any rate, arising within the cell itself, and we have no more

logical right to assume an unrecognized stimulus than in the case of the ticking of a clock. In the absence of knowledge to the contrary, the presumption is that the cell is discharged by the operation of its own never ceasing metabolism.

In our usual teaching as well as in our usual thinking it is customary to take account only of (1) the stimulus and (2) the reaction, and to regard each of these as a single process; whereas all the evidence goes to show that between the ordinary external stimulus, at any rate, and the release of energy there is usually interpolated a third process, which we have termed the "accumulation of discharging conditions" in our brief reference to the nature of electrical stimulation. We again meet with the suggestion of a similar process in the case of stimulation by a nerve impulse. Langley's work on the antagonism of nicotine and curare, as well as that of Keith Lucas on the "characteristic" of stimulation in different tissues, has led to the assumption of a "receptive substance" in skeletal muscle. The action of adrenalin also points to a similar "receptive substance" connected with the endings of the post-ganglionic automatic neurones. And yet is not this term "receptive substance" or "receptor" merely a name to hide our ignorance? and do we not really mean a physical or chemical process carried out by the cell protoplasm, as a whole, rather than a specialized irritable substance; a process, in other words, which results in the accumulation of "discharging conditions"? If this point of view is correct we must distinguish sharply between the stimulated action and the automatic action; they are alike in the second and third of the above-mentioned processes; they differ in that the accumulation of discharging conditions comes in the stimulated action as the result of an external influence (electric

shock, nerve impulse, or mechanical blow), while in the automatic action it results presumably from the cell metabolism.

In the central nervous system the best known and most successfully studied case of automatism is that of the respiratory center. The conclusion which Rosenthal drew from his experiments, that the nerve cells of this center send out rhythmic discharges when removed from all connection with afferent nerves, has been confirmed by all subsequent work, the experiments of Winterstein being especially conclusive on this point. Here again we are probably dealing with the development within the nerve cell of discharging conditions which may be influenced by the character of the environment, such as the tension of carbon dioxide or the concentration of hydrogen ions, or temperature or the presence of certain drugs; and we may repeat that there is no justification for speaking of these as stimuli, as we generally do. So far as the facts go, we may logically regard them only as external conditions which regulate the rate of development of the automatic cell processes or the character of the discharge which it evokes from the cell.

Until recently no other case of automatic nervous action was known. Some may have been suspected in the vaso-motor system or in the myenteric plexus; but no facts compelled the conclusion that they must be regarded as automatic actions. Recently, however, facts have come to light which argue strongly for an automatic basis to the nervous mechanism of locomotion. These movements, as already stated, have in the past presented to us the picture of an endless chain of reflexes, in which the afferent neurones are mostly the nerves of muscular sense, the complex of instreaming afferent impulses, ever changing as the movement proceeds, giving the

appropriate stimuli to the successive movements, which eventually come back to the starting point and so lead to the repetition of the series. To avoid misunderstanding, it may be well to say at the outset that no one denies that afferent impulses play an important rôle in locomotion. The phenomena of locomotor ataxia are conclusive evidence on that point; but so do afferent impulses over the pulmonary fibers of the vagus nerve play an important rôle in regulating the fundamentally automatic discharge from the respiratory center, without being in any way its exciting cause. The work of T. Graham Brown* suggests that the same thing is true of the rhythmic movements of locomotion. Brown shows that in a certain stage of ether narcosis in the decerebrate animal, when reflexes can no longer be elicited from the afferent nerves, rhythmic movements of flexion and extension occur in the hind legs; and furthermore, that these movements occur after the afferent nerves from the moving limbs are cut. In other words, these movements which suggest the basis of the movements of locomotion, involving as they do the alternate rhythmic action of antagonistic groups of muscles, are executed by efferent neurones without any stimulation from afferent neurones. They constitute an "endless chain," but not an endless chain of reflexes.

This discovery seems to me to be of sufficient importance to justify dwelling upon it at some length; and in order to obtain a clear picture of the possibilities, we may give briefly Brown's very plausible hypothesis of the nature of the nervous mechanism involved. A movement of this kind consists fundamentally in the alternate contraction of antagonistic groups of muscles. We may denominate the nerve

cells innervating each antagonistic group as a half-center, the two together making the entire nerve center for the given movement. Brown supposes that each half-center sends inhibiting collaterals to its antagonist (reciprocal innervation of Sherrington), so that when the flexors, for example, are being excited, the extensor neuro-muscular mechanism is inhibited. He then assumes that the efficiency of this inhibition rapidly diminishes—somewhat as the heart escapes from vagus inhibition—either by the fatigue of the inhibitory mechanism or by the increase of the discharging power of the inhibited cells. The result is that in a short time the inhibited center breaks through its inhibition, excites its muscles to contract and at the same time inhibits the previously active antagonistic half-center.[†] The repetition of these processes leads, of course, to the rhythmic movements referred to.

Brown further raises the very interesting question whether these automatic actions of locomotion do not present a more primitive form of nervous activity than the reflex. He points out the difficulty of imagining the origin of a reflex arc by natural selection, since neither the afferent nor the efferent limb would be of any use to the animal without the other; and it is almost impossible to conceive of both arising at the same time by any assumed process of evolution. It is far more easy to

*This theory assumes that the cells of both half-centers are automatic and subject to the same environmental conditions (*e. g.*, tension of carbon dioxid) governing their discharge. If both centers were in exactly the same physiological condition and subject to the same environmental conditions, they would discharge simultaneously and alternate rhythmic contractions of antagonists would be impossible. This condition of equal irritability, however, is rarely realized. When it does not obtain, one half-center will discharge first and, as explained, inhibit for the time being the discharge of the other.

* T. Graham Brown, *Journal of Physiology*, 1914, XLVII, p. 18.

suppose that the primitive nervous mechanism is the automatic one seen at work in the movements of narcosis progression. These would serve in the simplest animals the purpose of progression which may reasonably be regarded as among the first functions of coordination a nervous system would be likely to serve. In other words, the nervous mechanism of locomotion, like the nervous mechanism of respiration, is fundamentally an automatic mechanism. Later on afferent neurones are added to it, comparable to those of the pulmonary branches of the vagus. In this connection it is most significant that in general the same conditions so frequently referred to as stimuli of the respiratory center—lack of oxygen, excess of carbon dioxide, etc.—are the very conditions found to favor the movements of narcosis progression.

If, then, to the respiratory center, which has thus far stood in lonely glory as the one fully established example of automatic nervous action, we must add the fundamental centers of locomotion, the thought at once suggests itself that renewed investigation may find the same thing true of other actions which in the past we have too complacently catalogued under the head of reflexes. The field thus opened up is a large one.

AXON REFLEXES

Text-books of physiology usually record two observations, one by Langley, the other by Bayliss, which were not suspected of bearing any relation to each other and both of which have been difficult to fit into the orthodox scheme of nervous action. So far is this true that Langley's axon reflex has been relegated to the inglorious place of a laboratory curiosity which plays no rôle in normal life, while Bayliss's proposed theory of antidromic impulses has been treated with a polite but uncompromising skepticism.

The axon reflex is a reaction made possible by the branching which generally takes place at the end of an axon. Inasmuch as nerve fibers can conduct impulses in both directions, it follows that stimulation of one of the terminal branches will start an impulse traveling up to the point of union of the two branches, and then down the other branch to the end organ. The axons to a frog's sartorius, for example, branch soon after entering the muscle and it often happens that one branch will go to one side of the muscle, while another branch of the same neurone will pass to the opposite side. If, now, the lower third of the muscle be divided longitudinally, it is found that a stimulus applied to one half so as to excite its nerve fibers will cause contraction of the opposite half of the muscle. The same thing is rendered possible whenever a preganglionic efferent neurone passes through several sympathetic ganglia, giving off collaterals to postganglionic neurones in successive ganglia; in this case stimulation of the terminal branch of the preganglionic neurone will start an impulse centripetally and excite, through the collaterals, the cells with which these collaterals are connected. It is also well known that one must be on his guard against axon reflexes in testing the regeneration of nerve fibers, for it often happens that in the process of regeneration an axon of the central stump may branch before entering the peripheral stump; if these two axon branches find their way into different branches of the peripheral nerve trunk, stimulation of one of these branches may give an apparent reflex, which, however, is only an axon reflex.

These and other examples that may be cited are, however, only laboratory curiosities. Where the two branches of the axon end in a muscle or a gland neither branch can be stimulated at its ending except by

artificial means. If, on the other hand, the same axon should send one branch to a sense organ and another to a muscle, or gland, or blood vessel, we would have the possibility of an axon reflex as a normal event. Recent work suggests that this possibility may be realized.

In 1901 Bayliss⁴ found that stimulation of the posterior roots of the sacral nerves between the ganglion and the cord produces dilation of the blood-vessels of the hind limb. The natural explanation of the result, that certain vaso-dilator neurones may send their axons out by the unusual path of the posterior instead of the anterior nerve roots, was disproved by the fact that if the posterior roots are cut near the cord and degeneration allowed to occur, stimulation of the peripheral stump of the cut root still produces the dilation. In other words, the ganglion of the posterior root is the trophic center for some of the essential fibers concerned. From consideration of the known histological possibilities Bayliss concluded that the fibers producing the dilation are the ordinary afferent fibers from the pear-shaped cells of the ganglion, the distal axon being supposed to branch at its ending, one branch going to the sense organ, and the other to the blood-vessel. He furthermore supposed that in addition to serving as a trophic center for the afferent fiber, these cells may be reflexly stimulated by other afferent fibers and thus discharge "antidromic" impulses to the periphery; such impulses passing over the branch to the blood-vessel produces the dilation, while the impulse over the branch to the sense organ would be without effect ("law of irreciprocal conduction"). Physiologists have, however, looked askance on this conception of antidromic impulses, even as a working hypothesis.

⁴ Bayliss, *Journal of Physiology*, 1901, XXVI, 173; *ib.*, 1902, XXVIII, 276.

The very important experiments of Bruce,⁵ however, put the matter in a new light. It is well known that when an irritant is applied to the skin, a dilation of the arterioles (active congestion) ushers in the inflammatory reaction. Bruce shows that this will not occur if the area to which the irritant is applied is first rendered anesthetic with cocaine. It will occur immediately after section of the anterior roots or of the posterior roots, either centrally or distally of the ganglion; hence it is not a reflex through the cord or the ganglion. It will not occur, however, after the completion of the peripheral degeneration consequent upon section of the posterior root distally to the ganglion. In other words, it would seem to depend solely upon the integrity of the distal limb of the neurones of the posterior roots, and to be independent of any nerve cell whatever. This would seem almost to force⁶ the conclusion that we are dealing with an axon reflex. The posterior root fiber branches, as Bayliss supposed, at its ending, one branch going to the sense organ while the other serves as a dilator of the arterioles. The same fiber, probably one of pain, which carries the afferent impulse giving rise to the sensation of irritation produces also the active congestion of the region through its vascular collaterals.

If these observations prove well founded, the axon reflex becomes a reality in the normal functioning of the organism. instead of a laboratory curiosity. Moreover, the facts discovered by Bayliss receive their

⁵ A. Ninian Bruce, *Quarterly Journal of Exp. Physiology*, 1913, VI, p. 339.

⁶ The writer can imagine only one other possibility; namely, collaterals given off from afferent fibers distally to the ganglion may enter the sympathetic ganglia, which would thus serve as reflex centers. No such collateral communications in nerve trunks have, however, been described. Indeed it is the usual teaching that nerve fibers branch only in the ganglion or at their endings.

ready explanation without the help of the hypothesis of antidromic nerve impulses. Furthermore, if the axon reflex is the foundation of this inflammatory reaction, we may well investigate other reactions which in the past have been classed as reflexes, but upon inadequate evidence. So long as the reflex was supposed to be the only means by which stimulation of a peripheral sense organ can evoke a non-volitional reaction in another organ, all such reactions have been classed as reflexes, and this quite frequently without experimental proof.

CONDITIONED AND UNCONDITIONED REFLEXES

The main purpose of this paper is to emphasize neglected aspects of nervous action. Hence our treatment of reflexes, properly so-called, will be confined to emphasizing the fact that we probably include in the category of the reflex two entirely different kinds of nervous reaction.

It is an interesting fact that so common a phenomena as reflex action is somewhat loosely defined in our thinking. One will call it an action brought about by the stimulation of efferent neurones by one or more afferent neurones; another will add to this, "without the intervention of the will"; another will add, "without the causal intervention of consciousness"; while still another will add, "without the causal intervention of consciousness or the will." These four definitions are by no means identical, as I hope to show. All of them have in common the fact of stimulation of efferent by afferent neurones, stimulation being supposed to include both excitation and inhibition, and it being assumed that any number of intermediate neurones (first, second and third order, etc.) may be interposed between the afferent and the efferent nerves concerned. All would exclude the will from any causal connection with the reaction, and this leaves as the

chief point of difference in the above definitions the question whether we should exclude from the category of reflex action all cases where the nervous processes concerned in consciousness play, or seem to play, a causal rôle in the chain of events; for there are nervous actions which are in no sense volitional; which have an afferent and an efferent side, and hence resemble reflexes; but in which we encounter the nervous actions concerned with consciousness. The example which at once occurs to us is the so-called psychic secretion of saliva and gastric juice. To these we would add the no less striking case, brought to our attention by Cannon, of the stimulation of the secretion of adrenalin as the result of the major emotions of fear and anger. In all these cases there is the absence of conscious intention; indeed, the subject is unaware that the act of secretion is taking place; and yet the conscious process is the starting point of the efferent discharge. Shall we or shall we not call such actions reflex actions?

The answer to this question is, of course, entirely a matter of arbitrary definition. If we exclude the causal interposition of consciousness¹ from the reflex, such reactions are not reflexes; if we do not exclude it, they are. The decision in such an arbitrary matter, moreover, is determined on purely utilitarian grounds. Definitions exist only to insure clear thinking by keeping separate and distinct those things having some fundamental point of difference. Thus many would have us believe that there is no really fundamental difference between reflex and volitional acts; that the efferent discharge in the simplest reflex is accompanied by a momentary flash of something that corresponds to conscious intention;

¹ To avoid a cumbersome expression, the word "consciousness" is frequently used for the "nervous events connected with the state of consciousness."

and that there are all gradations between this and the highest development of the human will. Perhaps they are right; we will not argue the point; but we nevertheless retain our two categories of reflex and volitional actions, because so long as this conception of volition is a pure hypothesis it is unwise to forget that what are *subjectively* different may be *objectively* different as well.

The same principle of definition should be applied to the case under discussion. A reflex from which consciousness is entirely absent and one in which consciousness seems *subjectively* to play a causal rôle may, from the objective standpoint, be one and the same thing; and yet so long as this is only one of two opposing tenable hypotheses, it would seem to be the sensible thing to make a distinction between them.

One of the world's most eminent physiologists does indeed make such a distinction. I refer to Pawlow's differentiation between the unconditioned and the conditioned reflex. I can hardly think that Pawlow's very striking experiments upon which he bases this distinction are unknown to physiologists generally and all will agree that he is a man whose opinion should command attention; yet I find no notice whatever of this matter in the three admirable text-books of physiology which are most widely used to-day in England and America. Because of this and in view of the fact that this address is to a semi-popular audience I shall go into this matter at somewhat greater length than if I were speaking to specialists in neurology.

The distinction between the conditioned and the unconditioned reflex is well illustrated by the excitation of salivary secretion through the nervous system. When the taste endings are excited by food in the mouth, a purely reflex flow of saliva results.

The work of Miller^{*} seems to establish the existence of definite bulbar centers for this reaction, the gustatory fibers of the lingual and the glossopharyngeal nerves serving as the afferent neurones. On the other hand, the mouth may water "at the very sight of food." Here the afferent stimulus comes through the optic nerve, but it differs from that through the gustatory fibers in the fact that the reaction is secured only in a conscious animal. It is also more capricious in its occurrence; the whole setting of the nervous system must be right to have it occur at all; the subject must be hungry, the food must be appetizing, it is more apt to occur at the accustomed hour for meals. In short, a certain state of consciousness must exist to insure effective connection between the afferent optic neurones and the secretory efferent neurones. In the unconditioned reflex the nervous processes concerned in consciousness are in no way involved; it will take place in a decerebrate animal and may occur under anesthesia; it is a rare thing that the application of the proper stimulus fails to elicit it, although, like any other reflex, it may be inhibited, as in the old rice test. Above all, it is not easily lost by disuse, perhaps never permanently lost except by some actual atrophy of the neurones involved.

In a remarkable series of experiments Pawlow^o actually developed in animals conditioned reflexes which could by no possibility have formed part of the previous life of the animal or of its ancestors. Every time a dog was fed, a piece of ice was applied to a certain part of its skin. In the

* F. R. Miller, *Quar. Jour. Experimental Physiology*, 1913, VI., 57.

^o Pawlow, I. P., Huxley Lecture for 1906, *British Medical Journal*, 1906, Vol. II., p. 871; *Lancet*, 1906, Vol. 171, p. 911; *Science*, 1906, N. 8., XXIV., p. 613; see also Pawlow's articles on the same subject, *Ergebnisse der Physiologie*, 1904, III., 1, p. 177; *ib.*, 1911, XI., p. 345.

course of time (ten days or two weeks) the application of the ice to the same cutaneous area would evoke a flow of saliva without the formality of feeding. The application of ice to other parts of the skin was also effectual, apparently because the sensations of cold concerned in the result were not local, but more or less generalized. In another series of experiments a note of a certain pitch always accompanied the taking of food, and this stimulus, too, after sufficient repetition, could evoke the flow of saliva, while a note of distinctly different pitch was ineffectual. The reactions thus acquired were soon lost with disuse, although it is possible that if the "training" had been continued over much longer periods of time the reactions might have become more firmly fixed; it is even conceivable that they may take place in the absence of consciousness; that is to say, without the participation of cerebral centers; but these are questions which, so far as I am aware, experiment has not yet answered. Finally, they are more or less capricious; not infrequently the acquired response to the stimulus does not occur, thus contrasting with the response to gustatory stimulation, which seldom fails.

In what way is this type of reaction acquired? The phenomenon of reenforcement (of the knee jerk, for example) shows that activity of any one part of the nervous system causes the irradiation over the entire brain and cord of some exciting influence which, though itself minimal or even subminimal, yet adds itself to any other stimulus that may enter about the same time. Pawlow's work seems to show, moreover, that, when two nerve centers are habitually active at the same time, there is beaten out a path of conduction between the two, the two become "associated" so that activity of the one is liable to excite activity of the other. When, for example,

the knee jerk is reenforced by stimulus of sound, not only does such an irradiation from auditory centers pass to all parts of the nervous system, the sacral motor centers included, but one also irradiates from the sacral centers to all parts of the nervous system, the auditory centers included; and just as when there are two lights in a room the path between these lights is the most intensely illuminated portion of the room, so in the case in question the path between the two centers is most strongly in the excited state. If now this same combination of activity be repeated over and over again, this path becomes more irritable and conductive by use until we arrive at the condition shown in the above experiments of Pawlow where activity of one center can, of itself, excite activity of the other. It would indeed be interesting to know whether, just as clapping the piece of ice on the skin evoked a secretion of saliva, so the dog experienced a sensation of cold every time he ate.

The path of conduction or association thus established is presumably through the gray matter, perhaps with the help of the short neurones of the border zones.¹⁰ Our present knowledge of the anatomy of the nervous system is inadequate to give a satisfactory idea of the mechanism involved in the development of this new path of conduction; but it is inconceivable that the anatomical basis of the physiological connection between the centers in question should be the same as that pictured in the typical reflex arc of the text-books. Apart from the improbability of the development of new neurones, the observed facts of the capriciousness of the reaction and the ease with which, once acquired, it is lost by disuse determine as the logical course its provisional classification in a group of its own.

¹⁰ One thinks of the "neuropile" of some histologists as a possible tissue in which this path is blazed.

To look at the matter from another point of view, the present state of our knowledge would seem to indicate that the typical reflex of our text-books, the unconditioned reflex, is a congenital mechanism. The neurones concerned and the collateral connections of afferent and efferent limbs are born with us. It may require practise to bring the mechanism into perfect working order; but practise does not produce a new neurone nor have we any reason for thinking it can produce collateral connections which were not already laid down by heredity. The nervous element in locomotion is a case in point. The colt walks from the moment of birth; a human baby not until its second year, and then only after arduous trial and effort; but this does not mean that the nervous mechanism is congenital in the one case and acquired in the other; it merely means that the congenital nervous mechanism is in complete working order at birth in the colt, while in man either embryological development is not complete until later or else use is required to make congenital synaptic connections efficient. Despite the immemorial antiquity of the expression "learning to walk," it may well be questioned whether any child really learns to walk; whether the facts observed are not equally well explained on the theory that the child finally walks simply because at last the embryological development of its nervous mechanism of locomotion is complete, as is that of the colt at birth; and that the improvement which apparently results from its efforts is in point of fact merely the record of the progress of ontogenetic development.

With learning to talk the case is entirely different. Here there is no inherited mechanism leading to a uniform result in all individuals of the species. One child learns to speak English, another German, another Russian; and if the English child had been

taken after the first few months of its life to Russia and heard nothing but Russian, it would have learned to speak Russian as perfectly as it actually learned to speak English while growing up in its native country. In this case heredity has furnished a nervous system capable of acquiring just such associations as those described in Pawlow's experiments; we are dealing with a process in every way comparable to the conditioned reflex.

Finally, if the distinction between conditioned and unconditioned reflexes upon which Pawlow insists is correct, some old statements which take us back to our very introduction to the study of physiology need revision, or at least more accurate re-statement. When we speak of "habit being an acquired reflex" we really mean an acquired conditioned reflex. There is no reason for assuming that the reflex acquired by the repetition of volitional acts is the typical reflex arc; indeed there is every reason for believing the contrary. Paths of conduction become blazed between different lower centers because they are simultaneously excited in the volitional execution of an action, and a mechanism is acquired of whose nature we know next to nothing, but through which the act can be performed more and more easily with less and less conscious effort—or, in physiological language, with less and less participation on the part of the higher centers of the cerebrum. We are not concerned with the psychology of this phenomenon, much less is this the place for speculation as to the physiological mechanism involved. We are simply concerned with its classification as a distinct thing from the ordinary unconditioned reflex.

Perhaps when introducing this discussion of reflexes I laid undue emphasis on the rôle of consciousness in the acquisition of conditioned reflexes. In the examples

cited the nervous events associated with the state of consciousness do indeed play a conspicuous rôle. If, however, the essential thing about this reaction is what we have suggested, namely, that the connection between afferent and efferent fibers is a path blazed through the nervous substance rather than a definite localized conduction through specialized neurones, it would seem that consciousness comes so frequently into play merely because it is through the nervous substance of the cerebrum that such paths can be blazed most readily, and the activity of cerebral centers carries with it as a usual thing a state of consciousness. If this be true there is no reason why conditioned reflex associations may not arise between subcortical as well as between cortical centers; it is only necessary that the centers be simultaneously active, reflexly or otherwise; and possibly some cases of associated action of two bulbar or spinal centers—respiratory and vaso-motor, or respiratory and cardio-inhibitory—may be of this kind rather than distinct collateral connections between the neurones of the two centers. This is, of course, only a surmise, but it is clearly a possibility and certainly there is no evidence whatever to exclude it. We have been too quick to assume that coordinations are always effected by the same mechanism, and that too the kind of mechanism pictured in our typical reflex arc. An unproved assumption; and so long as it is an unproved assumption it is the logical thing to keep in separate categories the two classes of reactions which to-day are almost universally thought of as one and the same.

THEODORE HOUGH

UNIVERSITY OF VIRGINIA

THE DEDICATION OF THE NEW BUILDING OF THE MELLON INSTITUTE

The new \$350,000 building which will form the permanent home of the Mellon Institute

of Industrial Research and School of Specific Industries of the University of Pittsburgh, was formally dedicated on February 26. This building, the gift of Messrs. Andrew William and Richard Beatty Mellon, of Pittsburgh, was especially designed for the needs of the institute; it is distinctly modern in every respect, and complete facilities are provided for the investigation of manufacturing problems and for conducting industrial research according to the practical system of cooperation between science and industry, founded by the late director of the institute, Dr. Robert Kennedy Duncan. By this system, an industrialist having a problem requiring solution may become the donor of a fellowship by providing the salary of the researcher selected to carry out the investigation desired, the institute supplying every facility for the work—laboratory space, the necessary apparatus and supplies, library facilities and advice of a staff expert in industrial research, etc.

The new home of the Mellon Institute is a five-story and attic building. The basement contains seven rooms: the main storeroom, the boiler room, the electric furnace room, a heavy apparatus room, a room equipped for low-temperature work, the machine shop and a kitchen. On the first, the main floor, are located the general office, the director's suite, the office of the editorial department, the library, the office and laboratory of the assistant directors, the assembly hall, a special apparatus room and a dark-room laboratory. The second and third floors each contain ten large research laboratories and nine small ones; the fourth floor, which is not finished, will contain an identical number of laboratories as soon as the growth of the institute warrants its completion.¹ At the present time twenty-three fellowships are in operation and forty research chemists are engaged in a study of the variety of industrial problems under investigation at the institute.

While the Mellon Institute possesses an endowment of its own and has its own board of trustees, it is an integral part of the Univer-

¹ For a full description of the new building of the Mellon Institute, see *The Journal of Industrial and Engineering Chemistry* for April, 1915.

sity of Pittsburgh. The dedicatory exercises were accordingly held in conjunction with the annual charter-day exercises of the university.

The chancellor of the university, Dr. Samuel Black McCormick, presided at the dedication ceremonies, which took place at 11:00 A.M. in Soldiers' Memorial Hall. Following the address of the day by Dr. Rossiter Worthington Raymond, the dean of American mining engineers, on "Knowledge and Research," Dr. W. J. Holland, director of Carnegie Museum and formerly chancellor of the university, made the presentation speech in connection with the dedication of the Mellon Institute, on behalf of Andrew W. and Richard B. Mellon, the donors. After a brilliant eulogy of the Messrs. Mellon and a splendid tribute to their generosity, Dr. Holland said in part:

In a certain sense, Mr. Chancellor, this building is a memorial to Robert Kennedy Duncan. On one side of the entrance is a bronze slab inscribed with the name of Thomas Mellon; on the other side of the entrance is a bronze slab inscribed with the name of Robert Kennedy Duncan. But, Mr. Chancellor, this splendid edifice erected upon the campus of our university is more than a cenotaph. It not merely commemorates the names and careers of those of whom I have spoken, but it is intended to serve as the seat of advanced inquiries along scientific lines, which will tend to the promotion not merely of intellectual culture, but of industrial success, and that not merely in this great "workshop of the world," where it is located, but throughout the land. In creating this institution our dear friends have been actuated by a high and intelligent purpose. Large experience in great industrial enterprises has taught them the importance of chemistry and physics in their application to the industrial arts, and they feel that, wonderful as has been the progress made within the last century, there are untold mysteries in nature which have not yet been revealed, but which, if uncovered, are capable of being used for the welfare of mankind. And so they have created and are to-day placing in the custody of you, gentlemen of the board of trustees, this institution, which is capable of becoming, when wisely and intelligently administered, a mighty implement for the advancement of human welfare.

Dr. George Hubbard Clapp, president of the board of trustees of the university, delivered

the speech of acceptance. He expressed appreciation of the gift and understanding of the importance of the work for which the building has been erected.

The final ceremony of the exercises was the conferring of fifteen honorary degrees, as follows:

Doctor of Laws

Edward Williams Morley, honorary president of the Eighth International Congress of Applied Chemistry.

John Ulric Nef, head of the department of chemistry of the University of Chicago.

Arthur Amos Noyes, professor of theoretical chemistry and director of the Research Laboratory of Physical Chemistry, Massachusetts Institute of Technology.

Rossiter Worthington Raymond, secretary emeritus of the American Institute of Mining Engineers.

Ira Remsen, former president and professor emeritus of chemistry, Johns Hopkins University.

Theodore William Richards, professor of chemistry and director of the Gibbs Memorial Laboratory, Harvard University.

Doctor of Science

John Jacob Abel, professor of pharmacology, Johns Hopkins University.

George Hubbard Clapp, president of the Pittsburgh Testing Laboratory and of the Board of Trustees of the University of Pittsburgh.

Elbert Henry Gary, chairman and chief executive officer of the United States Steel Corporation.

John Hays Hammond, consulting mining engineer.

Henry Marion Howe, former professor of metallurgy, Columbia University.

Doctor of Chemical Engineering

William Hultz Walker, professor of chemical engineering, Massachusetts Institute of Technology.

Milton C. Whitaker, professor of industrial and engineering chemistry, Columbia University.

Doctor of Chemistry

Charles Lathrop Parsons, chief mineral chemist, Bureau of Mines.

Edgar Fahs Smith, provost of the University of Pennsylvania.

Immediately after the close of the dedicatory exercises, the trustees, faculty and guests of the university met at a luncheon in the University Club. The remainder of the after-

noon was devoted to an inspection of the new building of the Mellon Institute.

The recipients of honorary degrees were the guests of the university at the annual alumni banquet held at the Schenley Hotel from 6:00 to 8:30 P.M. The speakers at this dinner were Dr. Raymond F. Bacon, director of the Mellon Institute, who responded to "The Mellon Institute"; Dr. Walther Riddle, who gave a historical sketch of the department of chemistry of the university; Hon. Elbert H. Gary, chairman of the United States Steel Corporation; Dr. Theodore William Richards, who spoke on "The Practical Use of Research in Pure Science" and extended Harvard's congratulations to Pittsburgh upon the acquisition of the Mellon Institute; and Chancellor Samuel Black McCormick, who completed the toast list with an eloquent response to "The University," in which he stated that the gift of the Mellon Institute had placed a great responsibility upon the University of Pittsburgh as well as having been a priceless acquisition; that the university was ready to meet the responsibility and, he felt sure, would show the donors and the country at large that it would make the most of the great benefaction.

Judge Gary's address was in part as follows:

In humankind there is an element which is interested in, if, indeed, it does not actually enjoy reading or listening to, adverse references to the character or conduct of an individual or association of individuals, and, by reason of this fact, agencies for the collection and distribution of unfavorable comments have become more or less popular. A questionable kind of success is often realized by the individual or the publication whose energies are devoted to frequent and furious personal attack against the standing or the action of others. These efforts sometimes take the form of individual work, investigations by committees or commissions created by the legislatures or congresses, or, in exceptional cases, even by judicial branches of government, such as grand juries, with their inquisitorial power. Oftentimes the investigators are not only utterly incompetent, but they are prejudiced and willfully repress many of the pertinent and material facts. They seek to produce for circulation and criticism only information calculated to bring reproach upon the persons involved in the inquiry. No one is exempt from these criticisms.

Circumstances seem to show that we are approaching the time when the investigator will be investigated; when the criticizer will be criticized; when committees and commissions will be brought before other similar bodies for judgment. It would be interesting to the public if it could be informed of the real motives which have prompted some of the official inquiries, and if it could learn of the unfair methods which have been sometimes pursued, and if it should know the amount of governmental funds which have been appropriated for the use of committees and how they have been disbursed; in fact, if some of those participating could be subjected to the same scrutiny which they have exercised.

The general attitude of the great newspapers of to-day is fair and just. They influence and are influenced by the general public. They reflect the general sentiment. This is most important in considering the future welfare of this country.

If the picture which I have drawn is a true one, then the course before us, which leads to prosperity, success and happiness, is plain and we will pursue it. We must conduct affairs in our charge with the expectation that we shall be criticized.

After the banquet, the new building of the Mellon Institute was thrown open for a reception of friends of the institute. The rooms of the main floor were used for the reception, although the entire building was open for inspection. On the evening of February 27, the first Mellon lecture was delivered by Professor John Jacob Abel, of Johns Hopkins University, in the assembly hall of the institute; Dr. Abel's subject was "Experimental and Chemical Studies of the Blood and Their Bearing on Medicine."

W. A. HAMOR

THE MELLON INSTITUTE OF
INDUSTRIAL RESEARCH

CHARLES EDWIN BESSEY

THE Botanical Society of Washington at its one hundred and third regular meeting, March 2, 1915, unanimously passed the following resolutions upon the death of Doctor Charles E. Bessey, dean and professor of botany at the University of Nebraska.

WHEREAS, In the recent death of Professor Charles E. Bessey, botany has lost one of its ablest investigators and teachers, one of the pioneers in

the introduction of the present laboratory methods of teaching biology, and

WHEREAS, He was widely known and highly respected by his fellow botanists, and beloved by his numerous students in whose welfare and success he took the keenest personal interest, and

WHEREAS, The death of such a man comes as a personal loss to all American botanists; therefore be it

Resolved, That the Botanical Society of Washington express its deep sense of regret and extend to his family its deepest sympathy in their great bereavement; be it further

Resolved, That a copy of these resolutions be spread upon the minutes of this society and sent to the immediate relatives of the deceased and to

PERLEY SPAULDING,
Corresponding Secretary

SCIENTIFIC NOTES AND NEWS

THE annual general meeting of the American Philosophical Society will be held in the hall of the society at Philadelphia on April 22, 23 and 24, beginning at 2 P.M. on Thursday, April 22.

SIR J. J. THOMSON has been elected president of the Physical Society, London. Prince B. Galitzin has been made an honorary fellow of the society.

THE gold medal of the British Institution of Mining and Metallurgy has been awarded to Dr. Willet G. Miller, geologist of Ontario.

At the meeting of the Royal Geographical Society on February 22, Mr. Page, the American ambassador, presented to Dr. Scott Keltie, secretary of the Royal Geographical Society, the Cullum gold medal, awarded to him by the American Geographical Society.

MR. JOHN S. LONGWELL, C.E. (Cornell, '10), of the Reclamation Service, has been awarded the prize given annually by the American Society of Civil Engineers for the best paper by a junior member of the society.

THE Samuel D. Gross prize of the Philadelphia Academy of Medicine for the year 1915 has been awarded to Dr. John Lawrence Yates, Milwaukee, for his essay entitled "Surgery in the Treatment of Hodgkin's Disease." The amount of this prize is \$1,500.

MR. W. H. HOYT, C.E. '90, College of Engineering, University of Minnesota, assistant chief engineer of the D. M. N. Railroad, has been elected president of the Minnesota State Surveyors and Engineers Society.

THE Atlanta Neurological Society was organized February 11, with the following officers: *president*, Dr. E. Bates Block; *vice-president*, Dr. Hansell Crenshaw; *secretary*, Dr. Lewis M. Gaines. The society will hold its meetings on the second Thursday of each month.

THE *Journal* of the American Medical Association states that Dr. William J. Mayo, of Rochester, Minn., was the guest of honor at the Detroit Academy of Medicine on February 23. On February 22, Dr. Mayo was the principal speaker at foundation-day exercises of the department of medicine and surgery at the University of Michigan, Ann Arbor, and on February 24 the Kalamazoo Academy of Medicine gave a luncheon in honor of Dr. Mayo, after which he gave an address on "Some General Considerations which influence the Advisability of Surgical Treatment." Dr. Charles H. Mayo was the guest of honor at the twentieth annual banquet of the Kansas City Academy of Medicine, February 27. Dr. Jefferson D. Griffith presided and Dr. Mayo delivered an address on "Why Gastro-Enterostomy Fails to Cure."

THE Harvard University unit for service at the American Ambulance Hospital in Paris left on March 17, to serve until June 30. Members of the unit are: H. Cushing, '95, M.D., A.M., Moseley professor of surgery, as head surgeon; R. B. Greenough, '92, assistant professor of surgery, surgeon and executive officer; R. P. Strong, professor of tropical medicine, bacteriologist; R. B. Osgood, M.D., '99, instructor in orthopedics, orthopedic surgeon; B. Vincent, '93, assistant in surgery, assistant surgeon; W. M. Boothby, '02, lecturer in anaesthesia, anesthetist; F. A. Coller, '12, M.D.; E. C. Cutler, '13, M.D.; P. D. Wilson, and M. N. Peterson, '14, M.D., resident surgeons; L. G. Barton, Jr., '12, M.D., surgical assistant; O. F. Rogers, Jr., '12, M.D., medical

assistant; G. Benet, '13, M.D., laboratory assistant; and Miss Edith I. Cox, Miss Geraldine K. Martin, Miss Helen Park and Miss Marion Wilson, operating nurses.

DR. R. A. REEVES, professor of ophthalmology in the University of Toronto, president of the British Medical Association for the meeting held in Toronto in 1906, has become professor emeritus.

DR. B. H. A. GROTH has resigned his position as plant physiologist in the department of botany of the New Jersey College experiment Station, to become director of the experiment station under the government of the Republic of Panama. After April 15 he will be in Panama City.

DR. KARL VAN NORDEN, formerly in the research department of John Hopkins Hospital, who has been an officer in the German army since the beginning of the war, was seriously wounded at the battle of Lodz but is now about to return to the front.

DR. E. O. HOVEY, of the American Museum of Natural History, has gone to the West Indies to continue the studies on the volcanoes of the Lesser Antilles, which he began some years ago when the great eruptions on the islands of Martinique and St. Vincent occurred. He will devote his time particularly to the Grande Soufrière of Guadeloupe, Mount Pelé of Martinique, the Soufrière of St. Vincent and the boiling lake of Dominica, collecting gases from the fumeroles and making temperature observations, and taking note of the changes which have occurred since his visit in 1908. The expedition is undertaken through the aid given to the museum by the Angelo Heilprin Exploration Fund established by Mr. and Mrs. Paul J. Sachs.

THE departments of geology of Harvard University and Massachusetts Institute of Technology announce that Dr. Ralph Arnold will give a series of ten lectures on the "Geology of Petroleum." The first five lectures will be given from 4:30 to 5:30 P.M. on April 5, 6, 7, 8 and 9 in the geological department at Harvard. The last five lectures will be given from 4:30 to 5:30 P.M. on April 12, 13, 14, 15

and 16 in the geological department of the institute.

F. C. LANGENBERG, of Harvard University, and R. G. Webber, of Ohio University, Athens, Ohio, at the recent New York meeting of the American Institute of Mining Engineers read a paper on the Structure and Hysteresis Loss in Medium-Carbon Steel. It was illustrated by microphotographs of the physical structure, and curves of the hysteresis loss in a series of steels heat-treated to different temperatures.

PROFESSOR C. F. SHOOP, of the Experimental Engineering Department of the College of Engineering of the University of Minnesota, recently read a paper before the Minnesota Society of Engineers and Surveyors in annual convention in St. Paul. The title of the paper was "The Abrasion Value of Various Concrete Aggregates in Concrete Roads."

A MEMORIAL tablet has been placed in the house at Cosenza, Italy, where the eminent alienist, B. Miraglia, was born, and a similar tablet is to be placed in the insane asylum at Aversa, the scene of his work, and a street in Aversa is to be named after him.

MISS DAVY, niece of Sir Humphry Davy, has presented to the Royal Institution, London, a bust of the great chemist executed by Samuel Joseph in 1822.

FRANK ASBURY SHERMAN, professor of mathematics at Dartmouth College from 1871 until his retirement as professor emeritus in 1911, died on February 25 in his seventy-fourth year.

SIR GEORGE TURNER, distinguished for his work on the rinderpest and on leprosy, died on March 12 at the age of sixty-four years from leprosy, contracted during research work to discover a cure for the disease.

DR. E. VON ESMARCH, formerly director of the Kaiser Wilhelm Institute at Dresden, died on February 5, at the age of fifty-nine years.

DR. JULIUS ARNOLD, professor of pathological anatomy at the University of Heidelberg, died on February 6, in his eightieth year.

THE Washington Academy of Sciences held a joint meeting with the Biological Society

on March 11, in the Auditorium of the new National Museum, when there was a lecture by Mr. Wilfred H. Osgood, of the Field Museum of Natural History, who was engaged on a special investigation of the fur-seal question for the Department of Commerce during the summer of 1914. His subject was "Fur Seals and Other Animals on the Pribiloff Islands."

DIRECTOR JOHN F. HAYFORD, of the college of engineering, Northwestern University, addressed a group of graduate students and professors of the University of Wisconsin on the subject of "Isostasy" on March 1. That evening he addressed the Science Club of the same institution on the decision in regard to the Panama-Costa-Rico Boundary Dispute. Director Hayford was chairman of the committee appointed by the chief justice of the United States, which made a personal investigation and survey.

DR. LAFAYETTE B. MENDEL, professor of physiological chemistry in Yale University, addressed the Johns Hopkins Hospital Medical Society at Baltimore, March 1, on "Nutrition and Growth."

THE tenth lecture before the Harvey Society was given on March 13, at the New York Academy of Medicine, by Professor Elliott P. Joslin, of Harvard University, on "Carbohydrate Utilization in Diabetes, based upon Studies of the Respiration, Urine and Blood."

DR. CHARLES S. BERKEY, associate professor of geology in Columbia University, will give the last of the Jessup lectures on "Origin and Meaning of Some Fundamental Earth Structures" at the American Museum of Natural History on March 26. The subject of the lecture is "The Relation of Structural Geology to Practical Undertakings."

PROFESSOR EDWARD H. WILLIAMS, JR., of Woodstock, Vt., for many years head of the department of mining and geology at Lehigh and now a lecturer of the university, gave two lectures in February before the students. His subjects were "The Geology of the Lehigh Valley" and "The Formation of the Allegheny River."

THE American Association of Pathologists and Bacteriologists, of which Dr. Leo Loeb, St. Louis, is president, will meet in St. Louis, on April 2 and 3. The meetings will be held in the pathological department of Washington University Medical School and in the library of the St. Louis University. Preceding these meetings on April 1 will be held the annual meeting of the American Association for Cancer Research and the annual meeting of the International Association of Medical Museums. These meetings will be held in the laboratories of the Washington University Medical School.

THE seventh semi-annual meeting of the American Institute of Chemical Engineers will be held in San Francisco, Calif., from August 25 to 28. An itinerary is being arranged so that the natural scenery of the west may be seen and also some of the more important mining operations as well as the typical chemical industries of California.

THE senate of the Kaiser Wilhelm Society for the Advancement of Science at a session held on January 23, determined to break ground for the projected Kaiser Wilhelm Institute for Physiology and for the Study of the Brain. The Kaiser Wilhelm Institute for Biology is soon to be opened at Dahlem.

UNIVERSITY AND EDUCATIONAL NEWS

At the convocation at the University of Chicago, on March 10, Julius Rosenwald Hall, devoted to the work of the departments of geology and geography, was dedicated. The building, a gift from Mr. Julius Rosenwald, a trustee of the university, has cost approximately \$260,000.

THE Arnold Biological Laboratory, ground for which was broken at Brown University last summer, is practically completed and will be put into use for regular class work with the reopening of college after the spring recess. The building, which is three stories in height, 117 feet long and 52 feet wide, will cost when finished \$80,000, and \$30,000 more will be expended upon the equipment. The cost of the building will be covered by a bequest made to the university for the purpose by the late Dr.

Oliver H. Arnold, while the funds for equipment have been subscribed.

PROFESSOR THOMAS S. FISKE has been designated as administrative head of the Columbia University department of mathematics for two years beginning July 1, in the place of Professor Cassius J. Keyser, who retires at his own request.

MR. MORRIS M. WELLS, of the University of Illinois, has been appointed instructor in the department of zoology in the University of Chicago.

THE Benjamin Peirce instructorships in mathematics at Harvard University, the terms of whose establishment were recently announced in *SCIENCE*, have now been filled for the year 1915-16 by the appointment of Dr. Edward Kircher and Dr. George A. Pfeiffer.

DISCUSSION AND CORRESPONDENCE

THE FUNDAMENTAL EQUATION OF MECHANICS

TO THE EDITOR OF *SCIENCE*: Professor Huntington's letter in *SCIENCE* of February 5 is an important contribution to the subject of the teaching of elementary dynamics, but the fact that he and Professor Hoskins are not in agreement on "the question whether $F=ma$ or $F/F'=A/A'$ is the better form in which to introduce the fundamental equation of mechanics" shows that something remains to be said on the subject. In my opinion neither of these equations ought to be considered as fundamental, for both are derived from more elementary equations.

Professor Huntington objects to $F=ma$ for certain reasons. He might have made other objections to it: for example, the equation is not true in the ordinary English system (foot-pound-second) until it is hybridized by valuing either F or m in some other unit than pounds (poundal or gee-pound) or a in "gravitals" (instead of feet) per second per second (1 gravital = 32.174 feet),¹ or else the letter m is

¹ The writer invented the "gravital" and also the "timal" (=1/32.2 of a second) over 20 years ago as antidotes to the "poundal," merely to serve as "horrible examples" of what might be done in the way of introducing still further confusion into our systems of units. He also invented the

explained as not being quantity of matter in pounds, but only the quotient or ratio W/g . Neither is it true in the metric kilogram-meter-second system. (I do not think the metric people have yet tried to introduce a "kilogrammal" or a "gee-kilogram.") It is of course true in the dyne-centimeter-gramme-second system, but this system is only used in higher physical theory, and it should not be inflicted on young students. The equation $F=ma$ is, however, a handy equation to work with when it is understood that m is merely a conventional symbol for W/g .

The equation $F/F'=A/A'$ may be useful for some purposes, but I agree with Professor Hoskins in not accepting it as fundamental or as the best equation to be used as an introduction of the subject. Each of the equations being open to objection, I wish that both Professor Hoskins and Professor Huntington would consider the following treatment of the subject, and let me know what objections there are to it.

Quoting Professor Huntington's words: "The first serious problem which confronts the teacher of dynamics is the problem of making the student understand the effect which a force produces when it acts on a material particle" (I would substitute the word "body" for material particle).

Let us start with the student just out of the grammar school, who has never studied physics, but who understands the simplest forms of algebraic equations, and how to make $a=F/m$ out of $F=ma$. He already knows the ordinary meaning of the words time, space, force, matter (or stuff, solid, liquid or gas). He may be told that the word "body" means a piece or chunk of stuff, and that velocity is just another name for speed. He knows that force may be measured by a spring balance, and that the quantity of matter in a body may be determined by weighing it on grocer's even-balance scale or on a platform

"mamal" = 32.2 pounds, but that has got into some text-books disguised under the names of "gee-pound," slug, and "engineers unit of mass." The latter term is especially objectionable, for it has never been used by engineers.

scale; provided it is weighed at any place other than the imaginary "point of zero gravity."

The fundamental problem to be considered by the student is: Given a constant force F lbs. acting for T seconds on a quantity of matter W lbs., at rest at the beginning of the time, but free to move, what are the results, assuming that there is no frictional resistance?

The first result, which is already known by the boy, is motion, at a gradually increasing velocity. What the relation is between the elapsed time and the velocity may be determined by experiment. He may take a moving picture, with 50 films per second, of a body falling alongside of a rod marked with feet and inches. He may tow a boat having a load of 1,000 lbs. with a force of say 1 lb., exerted through a string and measured by a spring balance, alongside of a tow path on which a tape line is stretched; or there may be an Atwood machine in the high school on which experiments may be made. By these experiments he will learn the fundamental facts of dynamics and establish the fundamental equation. The facts are that the velocity varies directly as the time and as the force, and inversely as the quantity of matter, and the equation is $V \propto FT/W$ or $V = KFT/W$, K being a constant whose value is approximately 32, provided V is in feet per second, F and W in pounds and T in seconds.

The accurate determination of K requires the most refined experiments, involving precise measurements of both F and W , and of S , the distance traversed during the time T , from which V is determined, and precautions to eliminate resistance due to friction of air or water or of the machine used in the experiments. When these refined experiments have been made it has been found that the value of K is 32.1740, and this figure is twice the number of feet that the body would fall in *vacuo* in one second at or near latitude 45° at the sea level. It is commonly represented by g , or by g_0 , to distinguish it from other values of g that may be obtained by experiments on falling bodies (or on pendulums) at other latitudes and elevations. The fundamental equation then is

$$V = FTg/W \quad (1)$$

The velocity V is a derived quantity, derived from measurements of space (or distance) and time. If a body is moving at a uniform speed, such as the minute hand of a watch, V is a constant, and the distance varies directly as the time, and is the product of the velocity and the time, $S = VT$. But if the velocity varies directly as the time (uniformly accelerated motion), as in the case of the problem we are considering, then the distance is the product of the mean velocity and the time. Since in our problem the body starts from rest when the velocity is 0, and the velocity is V at the end of the time T , the mean velocity is $\frac{1}{2}V$ and the distance is $\frac{1}{2}VT$, whence $V = 2S/T$ and $T = 2S/V$.

The velocity V in feet per second, at the end of the time T is numerically equal to the number of feet the body would travel in one second after the expiration of the time T if the force had then ceased to act and the body continued to move at a uniform velocity.

The fundamental equation might be written $2S/T = FTg/W$, which is equivalent to $S = FT^2g/2W$, but as this is somewhat more cumbersome than the simpler-looking equation $V = FTg/W$, this latter equation is more convenient as the fundamental equation. It expresses the facts that the velocity varies directly as F and T and inversely as W , and that the velocity equals the product of F , T and g divided by W . Let us further consider the two equations $V = FTg/W$ (1) and $S = FTg/2W$ (2).

We have dealt with four elementary quantities F , T , S , W , one derived quantity V , and one constant figure 32.1740. It is understood that F is measured in standard pounds of force, the standard pound of force being the force that gravity exerts on a pound of matter at the standard location where $g = 32.1740$.

Each equation contains four variables V , F , T , W , or S , F , T , W , and in either equation if values be given to any three out of the four the fourth may be found. By ordinary algebraic transposition, or by giving new symbols to the product or quotient of two of the variables, many different equations may be derived from them, some of which are more curious than

useful. It is well not to give the student too many of them or he will become confused.

Here are some conclusions that may be derived from the equations, (1) and (2).

From (1), let $F=W$, the case of a body falling at latitude 45° at the sea level; then $V=gT$. If T also $=1$, then $V=g$, that is the velocity at the end of 1 second is g .

In the equation $V=gT$ substitute for T its value $2S/V$ and we have $V=2gS/V$, whence $V^2=2gS$. In the case of falling bodies, the height of fall H is usually substituted for S , and we obtain $V=\sqrt{2gH}$ (3).

Equation (2) with $F=W$ gives $V=\frac{1}{2}gT^2$.

From (1), by transposition we may obtain $FT=W \times V/g$ (4). The product FT is sometimes called impulse, and to the expression $W \times V/g$ is given the term momentum. It is usually written W/gV , but there is no reason why, except that it is customary, and it has been found convenient to use the letter M instead of W/g , so that the equation becomes

$$FT = MV \quad (5)$$

Impulse = Momentum

In (4) we may substitute for T its value in terms of S and V above given, viz., $T=2S/V$ and obtain $F2S/V = MV$; whence $FS = \frac{1}{2}MV^2$ (6). The product FS is called work, and the expression $\frac{1}{2}MV^2$ kinetic energy, whence work expended = kinetic energy.

Acceleration.—The quotient V/T is called the acceleration. It may be defined at the rate of increase of velocity, the word rate, unless otherwise stated, always meaning the rate with respect to time, or "time-rate." In the problem under consideration, the action of a force in a body free to move, with no retardation by friction, the acceleration is a constant, $V/T=A$. The quantity g is commonly called the acceleration due to gravity, but it also may be considered either as an abstract figure, the constant g in equation (1), or as the velocity acquired at the end of 1 second by a falling body, or as the distance a body would travel in 1 second at that same velocity if the force ceased to act and the velocity remained constant.

Equation (6) then may be written

$$F=MA \quad (7)$$

Force = M times the acceleration.

If a given particle [body] is acted on at two different times by two forces F and F' , and if A and A' are the corresponding accelerations, then

$$\frac{F}{F'} = \frac{MA}{MA'} \text{ whence } F/F' = A/A'. \quad (8)$$

Equation (7) is called the fundamental equation by Professor Hoskins, while equation (8) is called fundamental by Professor Huntington, but it is shown above that they are derived from the more fundamental equation $V=FTg/W$.

Summary.—Take equation (1), $V=FTg/W$

- (1). Substitute $2S/T$ for V , $S=FT^2g/2W$
- (2).

Take $F=W$, then $S=\frac{1}{2}gT^2$,

$$\text{and } V=\sqrt{2gH} \quad (8)$$

From (1) by transposition $FT= WV/g$ (4)

Substitute M for W/g , $FT= MV$ (5).

In (5) substitute $2S/V$ for T ,

$$FS = \frac{1}{2}MV^2 \quad (6)$$

In (5) substitute A for V/T , $F=MA$ (7)

Apply (7) to the case of two forces acting at different times on the same body

$$F/F' = A/A' \quad (8)$$

In this treatment the ambiguous words "weight" and "mass" have purposely been omitted.

If there is any easier way of "making the student understand the effect which a force produces when it acts on a material particle" than to have him study the above discussion and solve examples by its aid, it is very important that it should be found and incorporated in the text-books.

WM. KENT

A COURSE IN AGRICULTURE FOR NON-TECHNICAL COLLEGES

THAT there is an interest in agriculture as a subject of study in colleges or higher institutions in addition to that met by the state agricultural colleges, is manifested by the introduction a few years ago into the curriculum, in certain institutions (e. g., Syracuse and Miami Universities) of several subjects associated with the work of the land-grant colleges. Further evidence is shown in the

preparation by one of the professors of a text on agricultural education which is regarded as well toward the head of the list upon that subject. But there seems to be still a field for educational work in agriculture, apparently not touched by any of the current courses, by which the subject matter of botany, zoology, geology and meteorology can be correlated with history through the common ground of agriculture.

The recent article upon agricultural botany, by Dr. Copeland, in *SCIENCE*, September 18, has suggested some details of such possible correlation in addition to a general plan already in mind. The scope of the course in mind is just the reverse of the work as ordinarily catalogued as a "Course in Agriculture" in the state colleges. Such courses take the general subject, agriculture, and divide it into its component parts, assigning portions to agronomy, to horticulture, to animal husbandry, soils, farm management and the other familiar departments. The other plan would take the work in the botanical laboratory and would show where it is of common application in the regular work of the farm; and in zoology, why the domestic animals are so useful to man through their anatomy and physiology, in place of merely noting their places as mammals in taxonomic scheme. It would show that the development of the technique of agriculture has been the companion, if not the guide, to advancing civilization through ethnology and anthropology to modern history, commercial and industrial.

This is an ambitious aim and would require much careful selection of material, before it could be regarded as definitely outlined. The final form would be an adjustment of the ideas of several rather than the dictum of an individual, as has been the case with college-entrance requirements in the sciences, although no official sanction, outside the several institutions which might offer the course, would be called for. As here outlined, the principal work of the course would be cared for by the regular staff of instructors in botany, zoology, geology, etc., the specialists in agronomy, livestock or soils being left with their respective subjects in the technical school. Under such

regular teachers, however, those details in their course which relate to agriculture in any manner are to be brought out and made the peg upon which to hang the several facts of structure, behavior or adaptation observed.

The field as a whole may be divided into four sections, as follows:

1. *Soil*.—The basis of agricultural activity. Origin of soils; types of soil; properties of different soils; soil biology; soil management.

2. *Plants*.—The factory of agricultural products. Seeds; growth; nutrition; reproduction; weeds and diseases; phytogeography; agricultural ecology.

3. *Animals*.—The product of agricultural factory. Nutrition; anatomy; physiology; breeds; uses; predacious and beneficial species.

4. *Man*.—The controlling factor in agriculture. Races, civilization, colonization; commerce; rural and urban; raw materials and manufactures.

In attempting to assign to these topics their places in the four-year course, it must be remembered that it is not practical agriculture, but fundamental agriculture, that is in mind; it is not an attempt to make farmers, but to show how the farmer gets the results he does from certain methods of procedure, and why he is using those methods instead of some others, in a historical and economic, rather than technical and special study. Thus under the subject of soils, the danger of severe washing of fall-plowed fields in the south would be contrasted with the beneficial effects of the frost work on similarly treated fields in the colder states. Through the aid of the departments or instructors in bacteriology and mycology, relation between soil bacteria, root-infesting fungi and other organisms could be shown as scientific reasons behind the observed benefits of crop rotation, thus connecting the work on soils with that on crop plants. In the consideration of plants, the fact that upon green plants all animal life depends is the keynote, with details added discussing the parts of such plants utilized in particular cases, thus connecting directly with the study of those animals which make direct use of plant tissues for food. Under animals, the adaptation of the teeth to hard-stemmed forage

plants and the ease with which such crops are raised, should be brought out as important details in the usefulness of horses and cattle, as well as their anatomical adaptation to the work of pulling or carrying loads, and their physiological adaptations for meat and milk production.

The treatment of man as outlined would involve as much of the advanced sciences of anthropology and ethnology as one had time for; would naturally involve ancient history, in connection with grain commerce of Rome and her colonies; would take up the development of agricultural communities through the feudal system to the modern village of tenant farmers, and the rise of the freeholders, especially in the new settlements. The relation of established feast days (*s. g.*, Feast of First Fruits) of the ancient tribes, to events of the agricultural year would introduce the religious side of man, and the importance of conserving the produce of his labor, would serve to connect the ideas of property, ownership, wealth, capital and law.

The simpler relations would naturally be assigned to the earlier years of the course. Thus the subjects relating to plant life, in their fundamental details could be given in the sophomore year, supplementing the freshman work in botany; some work would likely be well retained to a later period. Soil work should follow the first year's work in chemistry and in physics, as the general properties of soils are in accordance with the principles learned in those subjects. The study of animals in relation to agriculture would be a good junior subject, as the additional year of work would make it the easier for the student to follow the course, and to grasp the essential points of structure, behavior, conditions of existence among wild and domestic animals, and similar details after he has had the less complex relationships among plants brought out in the sophomore work.

The study of the relation of man to agriculture, as suggested, should come in the senior year, in order that the work in history, economics, engineering and science may be available for use to aid in the development of the course by each man in the class bring-

ing to it as broad a basis of work as possible. The topics introduced at this stage might easily serve as the basis of further study by the few specially interested along the lines of colonial, economic or industrial development. Frequent assignments of readings would be necessary, as the material is scattered and must be brought together under the new viewpoint.

Some suggestions have been found in several text-books on agriculture, agricultural education, farm management and similar topics, more or less along the lines here suggested, but in most cases, the discussion was from the standpoint of technical agriculture, as would be expected. Particular chapters could, however, be selected from a number of such books, to be used as collateral reading by either of the four college classes, suitably supplemented by lectures presenting the desired viewpoint, and developing the central theme. This may be briefly stated as follows: Agriculture as the oldest industrial occupation of man is the basis of all his later achievements, and supports him in his highest attainments. The course might be designated as one in "The development and scope of agriculture" and could be a lecture course supplemented by specified laboratory and class work in the several departments involved. The course might also be developed as a series of short courses, something on the plan of the "summer school" work, correlated by a carefully prepared syllabus or outline, each teacher selecting those phases of the work most closely related to agriculture in its broadest sense, and emphasizing the relation of his subject to the general topic.

FREDERICK H. BLODGETT

SCIENTIFIC BOOKS

Psychology: General and Applied. By HUGO MÜNSTERBERG. New York and London, Appleton, 1914. Pp. xiv + 487.

Professor Münsterberg's latest work breaks away from the traditional presentation of psychology in many respects. The most novel features are the author's treatment of mental data from the teleological standpoint and the

emphasis which he lays on applied psychology. Each of these aspects of the subject is developed at considerable length.

The main body of the work is devoted to scientific psychology; but even here the treatment is out of the ordinary. We miss the usual detailed description of the nervous system and end organs. The author expresses his conviction in the preface that details from accessory sciences such as anatomy do not belong in an outline work on psychology. On the other hand, he believes that psychology should embrace social as well as individual phenomena, and accordingly several chapters are devoted to an examination of mental processes in the social group. Professor Münsterberg does not venture into the field of animal psychology, but he gives considerable prominence to "behavior" in the human sphere. In this connection he points out that tools are human extensions of the motor end-organs, while language is a highly specialized motor function, comparable however with other forms of motor activity.

After defining the scope of psychology in two opening chapters, the author proceeds to the scientific description and explanation of mental events. This aspect of the subject he terms *causal* psychology, to distinguish it from the purposive treatment which follows. More than half of the volume is devoted to the causal presentation, which for most writers constitutes the whole of scientific psychology. This part of the work is exceptionally clear and readable. One is reminded of the author's late colleague, William James, whose interesting style and picturesque illustrations add much to the value of his classic text.

It is to be regretted that Professor Münsterberg has not imitated his predecessor's fullness of treatment as well. In endeavoring to compress his material within too narrow limits he is compelled to curtail the discussion of certain topics unduly. For example, one would desire a more exhaustive examination of imagery, discrimination, abstraction and reasoning than the volume supplies. In this part of the work the author insists on a thoroughgoing scientific procedure. His psychological analysis rests on a rigid psychophysical basis

and he aims at a complete mechanistic explanation of mental phenomena through the physiological processes which accompany them.

Professor Münsterberg classifies the elementary psychophysical processes under four heads: stimulation, association, reaction and inhibition; the complex processes include perception, ideas, activity, inner states and personality. A striking feature here is the grouping of actions, attention and thought processes together under the head of *activity*. Inner states are divided into simple feelings of pleasure and displeasure, emotions, and esthetic and intellectual attitudes.

The transition from individual to group processes is made through the study of race, sex, age and individual differences. It may be questioned whether such variations do not belong more properly to comparative than to social psychology; but as the author points out, the differences among individuals facilitate their grouping into social unity. The social grouping itself depends upon three elementary processes: union, submission and aggression. Those factors work together and result in the complex social processes of organization and achievement.

The second part of the work is devoted to purposive psychology. Here the object is not to describe the inner life, but to understand its meaning. By a curious *volte-face* the author discards the scientific explanation of mental phenomena which he has hitherto insisted upon rigorously, and considers only their teleological bearings. Psychology regarded from this standpoint is "entirely removed from the world of describable objects and understood as an account of those functions in the personality which point beyond themselves and are felt as deeds of the subject" (46). In connection with this change to the subjective standpoint Professor Münsterberg renames the facts themselves. Instead of psychical elements we have experiences; instead of perception we have immediate reality; ideas become meaning, activity becomes the will.

It is somewhat difficult to grasp the significance of this transformation. Granting that a plexus of ideational elements may be called

meaning, and that a certain plexus of activities constitutes will, the scientist may still question the propriety of abandoning the associational basis of meaning or ignoring the causal sequence of volitional acts, as Professor Münsterberg appears to do.

In other sciences the speculative hypotheses which have stood the test of criticism have been attempts to amplify or reconstruct the principles discovered by the science itself, rather than to deny its fundamental generalizations. Professor Münsterberg's reconstruction of psychology, on the contrary, starts out by repudiating the generalizations based on observed temporal sequences, and assuming that the acts of our inner life are not contained in time (301), that "our mental life is free" (296).

It would appear that the author makes altogether too crucial a distinction between *cause* and *purpose*. His interpretation of both terms is open to challenge. The analysis of the *purpose* concept has never been fully carried out, but at least we know that "prevision" and "activity toward an end" admit of biological interpretation in harmony with mechanistic principles. As for causality, the author's use of the concept is not in harmony with Hume's classic analysis, which demonstrated that "necessary" connection is not an essential feature of the causal sequence.

Science to-day generally accepts Hume's conclusions. The chemist and physicist regard the laws of their sciences as merely generalized statements of observed facts. They distinctly refuse to commit themselves as to whether causal sequences *must* be as they actually are. Since Darwin's time most biologists have interpreted the evolution of species and the stages of individual development in the same way. Scientific explanation at the present day does not seek to impose anthropomorphic compulsions upon nature. Nature has been found to be self-consistent in the past; the scientist assumes that the same self-consistency will be observed in the future. The generalized notion of uniformity and self-consistency is all that is implied in the scientific conception of *law*.

Professor Münsterberg interprets the term "law" as involving a "necessary connection" between phenomena. For example, if we have met a man and heard his name, "the law of association makes it necessary that if we meet the man again his name comes to our mind" (22). The author states specifically that "the scientist has a right to claim that all his laws are meant as expressions of causal necessity" (31). Yet this necessary connection is just what most physical scientists plainly disavow. They aim merely to generalize the uniformities of sequence observed in nature.

In any science it is quite legitimate to suggest a working hypothesis which goes beyond the facts and reconstructs them. The electron theory and Mendeleeff's periodic law are such reconstructions of physical and chemical data. So in psychology Professor Münsterberg may find grounds for his theory of "self as a system of purposes." But such a theory should be based on scientific foundations. Instead of two standpoints, the causal and purposive, we should have systematic description of mental phenomena and a suggested reconstruction; the latter should amplify the empirical laws, instead of rejecting them.

The author's attempt to formulate a system of psychology from the teleological standpoint will not appeal to the plain empirical psychologist, because it runs counter to the scientific development of the subject. It transcends the scientific limitations of both cause and purpose. "Necessity" is an anthropomorphic addition to causality. Failing to find any such necessary connection between mental events, the author throws his science to the winds and bases his teleological reconstruction on an equally anthropomorphic interpretation of purpose. The result is perplexing. It is not easy to attach a definite meaning to such statements as "the free act is free because it has no causes" (324). Nor can we take a definite attitude toward the assertion that "we can not imagine a purposive act the meaning of which is not a negation of an opposite purpose" (316).

In the third part of the volume Professor Münsterberg returns to more familiar terri-

tory and discusses the applications of psychology to science and art. He indicates the line of demarcation between psychology and the human sciences as follows: The understanding of mental operations is valuable in the study of history, sociology, etc., but the interpretation of the subject-matter in each case belongs to the special science and not to psychology. In his closing chapters the author considers the applications of psychological data and methods to education, law, economics, medicine and culture. To this applied field he gives the name psychotechnics. These chapters offer a most interesting presentation of the recent progress in applied psychology, a line of development which seems likely to bring about a closer connection between psychology and the professions.

Whether or not the reader agrees with Professor Münsterberg's fundamental positions, he will find the present work most stimulating and suggestive.

HOWARD C. WARREN

PRINCETON UNIVERSITY

Design of Polyphase Generators and Motors.

By HENRY M. HOBART. McGraw-Hill Book Company.

In "Design of Polyphase Generators and Motors," Mr. Hobart takes up the design of a simple three-phase generator and an induction motor from the standpoint of a designing engineer. This occupies the major portion of the book, but there are in addition two chapters devoted to a comparison of synchronous motors and induction motors and to the induction generator. Much useful information and many valuable tables compiled from empirical data obtained from existing machines are included.

The book follows the plan, outlined by the author in its preface, of taking up immediately without any preliminary discussion the design of a three-phase generator of definite rating, introducing the principles involved when required as the design progresses. In addition to the design of a three-phase generator, the design of a polyphase induction motor is also considered. The book should be valuable to the young designer who has a fair

knowledge of the principles underlying operation and design of electrical machinery.

It is to be regretted that a portion of the book is not devoted to a simple analytical study of the effect on the operating characteristics of machines of modifying their dimensions and windings in order that the young designer might learn to analyze existing designs and to be able to judge the fitness of any particular design for a definite class of service.

Two appendices give a full bibliography of the papers dealing with polyphase generators and motors which have been printed in the *Proceedings* of the American Institute of Electrical Engineers and in the *Journal* of the British Institute of Electrical Engineers.

RALPH R. LAWRENCE

Synchronous Motors and Converters. By ANDRÉ BLONDEL. Translated from the French by C. O. MAILLOUX. McGraw Hill Book Co. 1913.

"Synchronous Motors and Converters" is a translation of the admirable little book by André Blondel entitled "Moteurs Synchrones à Courants Alternatifs." Several chapters have been added to the translation in order to increase the scope of the book and to bring it up to date. The translation is divided into three parts. Part I. is a translation of the original book with one chapter added by Professor C. A. Adams, of Harvard University. Part II. relates to Rotary Converters and is made of new material by Professor Blondel and a translation of papers presented by him at the Paris Congress in 1900. Professor Adams has also added a chapter to this section relating to the split-pole converter. Part III. contains reprints of papers presented by Professor Blondel at the St. Louis Electrical Congress in 1904, relating to his "two reaction" method of treating the armature reaction of alternators.

The first part of the book takes up the general principles of synchronous motors and a study of their operation under different conditions, and is particularly valuable in giving the development of well-known Blondel bi-

polar circle diagram. In translating Professor Blondel's "Moteurs Synchrone," Mr. Mailloux has rendered a valuable service to English-speaking electrical engineers.

RALPH R. LAWRENCE

Storage Batteries. By HARRY W. MORSE.
New York, The Macmillan Company. 1912.

This little book of 263 pages on storage batteries is based upon lectures given by Professor Morse at Harvard University. It deals only with the theory and the characteristics of storage batteries. No attempt is made to discuss problems connected with storage-battery engineering. The first chapters are devoted to the laws underlying the action of storage cells and to the consideration of the fundamental reactions. A short discussion of the ionic theory and the energy relations involved in the action of a storage cell is included. Later chapters are given up to the operating characteristics, efficiency and capacity, and to the general principles underlying the methods of forming modern storage battery plates. The diseases and care of storage batteries are also discussed. In the last chapter a few pages are devoted to the iron-nickel-alkali cell. "Storage Batteries" is an excellent little book for any one who wishes a simple treatment of the theory, action and care of lead-lead-peroxide storage batteries.

RALPH R. LAWRENCE

SPECIAL ARTICLES

CORRELATION BETWEEN EGG-LAYING ACTIVITY AND YELLOW PIGMENT IN THE DOMESTIC FOWL¹

In the Leghorns and the so-called American breeds, such as the Plymouth Rocks, yellow, in the form of yellow fat,² is present in varying amounts in the legs and beak. In these breeds, individual birds may undergo considerable change in the amount of the yellow pigment visible. The paling or yellowing of the

legs has been attributed by poultrymen to various environmental factors. Of recent years, some individual poultrymen, however, have claimed that paling of the legs is due to heavy laying.³ The requirements of the "Standard of Perfection," which controls judges in the show room, as well as the common practise of poultry breeders, are opposed to a belief in any connection between laying and leg color. Woods⁴ under the title, "Has Leg Color Value Indicating Layers?" in the most recent discussion of the subject, concludes:

Personally we believe that, as a practical guide in the selection of heavy layers, . . . the leg color of itself has no real value.

So far as the writers are aware, no published data are available which show in how far the leg color may be of any value in selecting the laying hen, and such suggestions as have been made in this connection have confined themselves almost entirely to a consideration of the legs alone. The results tabulated in the present paper show conclusively, it is believed, that a close connection does in fact exist between the yellow pigmentation in a hen and her previous egg-laying activity, and that, in Leghorns, the color of the ear-lobes is perhaps a better criterion of laying activity than either legs or beak and is more readily recorded.

The hens investigated were in the egg-laying contest at Storrs, Conn., and were handled essentially alike. The influence of environmental factors, therefore, can be largely neglected. The amount of yellow was measured by means of the Milton Bradley color top, which, when spinning, acts as a color mixer. The top readings were taken of the White Leghorns listed in Tables I. and II. at three different periods in October.

In Table I., the records at the three different readings have been used. A bird laying on the day of record, or on a later day within the month is considered to be laying and credited

with a zero. If she laid on the day before the record but not later, she is credited with one "day since laying" and in a similar way a longer period of inactivity in laying is indicated by a larger number of days since laying. With the exception of a few cases where this is not possible three records were taken of each bird. Since October is the season of decreasing egg production, the majority of the birds increased their quantum of yellow and consequently most birds are listed in more than a single color grade. Beginning with the 41 records in

be seen that in general as the percentage of yellow increases the egg production falls off, and that the correlation is most marked during the periods nearest the time when the records were taken. A distinct correlation with color seems to show in the yearly averages but is largely an indirect one. It is generally only the best birds—those that make the large yearly records—that are laying in October. Therefore, any method that selects the laying birds at this season will select at the same time the birds laying above average

the 5-10 per cent. color grade, which show an average of only 0.4 days since laying, the number of days increases consistently with the amount of yellow in the ear-lobes. The percentage of records that indicate actual laying drops rapidly from 87.8 per cent. for 5-10 per cent. yellow to zero for grades of yellow above 30 per cent. The three cases of laying among records above 30 per cent. yellow were for sporadic layers. The table shows that it is practically certain that a bird with an ear-lobe showing more than 30 per cent. yellow at the time of the records is not in a laying condition.

Table II. shows the percentage of yellow in the ear-lobes of 312 birds according to the color records of October 20, together with egg records for the different color groups. It will

throughout the year, and consequently give high yearly totals. It will be observed that 30 per cent. seems to be a critical amount of yellow. Above this amount comes the sudden drop in egg production for the months of September and October and also above 30 per cent. yellow the yearly totals fall to between 130 and 140 with but slight change thereafter.

By the use of beak and leg color, similar results to those shown in Tables I. and II. have been worked out for other breeds than Leghorns and more complete data are being published elsewhere.

The data presented indicate a connection between the amount of yellow pigment showing in a hen and her previous laying activity. The most natural assumption is that laying removes yellow pigment with the yolks more

rapidly than it can be replaced by the normal metabolism, and in consequence, the ear-lobes, the beak and the legs become pale by this subtraction of pigment.

PROCEEDINGS OF THE ANNUAL MEETING
OF THE AMERICAN SOCIETY OF
ZOOLOGISTS HELD IN PHILADELPHIA 1914

THE American Society of Zoologists, in conjunction with the American Society of Naturalists and Section F of the American Association for the Advancement of Science, held its twelfth annual meeting (the twenty-fifth annual meeting of the society since its establishment as the American Morphological Society) in the zoological laboratory of the University of Pennsylvania, Philadelphia, Pennsylvania, on December 29 and 30, 1914.

At the session for transacting business, held on the afternoon of December 30, the following officers for the society were elected for the year 1915:

President—William A. Loe, Northwestern University, Evanston, Ill.

Vice-president—William E. Ritter, Scripps Institution, La Jolla, Cal.

Member at large of the Executive Committee—D. H. Tennent, Bryn Mawr College, Bryn Mawr, Pa.

Upon the recommendation of the executive committee the following persons were elected to membership in the society:

Cora J. Beckwith, assistant professor of zoology, Vassar College; Ralph V. Chamberlain, museum of comparative anatomy, Harvard University; Margaret H. Cook, instructor in zoology, Wellesley College; J. A. Dellefsen, assistant professor of genetics, University of Illinois; Howard E. Enders, associate professor of zoology, Purdue University; Nathan Fasten, instructor in zoology, University of Washington; Richard B. Goldschmidt, in charge of department of genetics, Kaiser Wilhelm Institut für Biologie, Berlin (Yale University); Joseph Grinnell, director, museum of vertebrate zoology, University of California; Carl G. Hartman, adjunct professor of zoology, University of Texas; Mildred A. Hoge, instructor in zoology, Indiana University; A. G. Huentsman, lecturer in biology, University of Toronto; B. F. Kingsbury, professor of histology and embryology, Cornell University; F. H. Kreeker, assistant professor of zoology, Ohio State University; K. S. Lashley, Adam T. Bruce Fellow, Johns Hopkins University; W. H. Longley, professor of botany, Goucher College; Elmer J. Lund, instructor in zoology, University of Pennsylvania; Roy L. Moodie, instructor in anat-

omy, University of Illinois; Julia E. Moody, instructor in zoology, Wellesley College; Anna H. Morgan, associate professor of zoology, Mount Holyoke College; T. S. Painter, instructor in biology, Yale University; B. M. Patten, instructor in histology and embryology, Western Reserve Medical School; B. H. Ransom, chief, zoological division, Bureau of Animal Industry, Washington, D. C.; E. E. Reinke, instructor in zoology, Rice Institute, Houston, Texas; Lucy W. Smith, instructor in zoology, Mount Holyoke College; A. H. Sturtevant, Cutting Fellow, Columbia University; Shiro Tashiro, instructor in physiological chemistry, University of Chicago; Ernest I. Werber, assistant in biology, Princeton University; Paul S. Welch, assistant professor of entomology, Kansas State Agricultural College.

The secretary-treasurer of the society was authorized to prepare and print a list of the names, addresses, etc., of the members and officers elected at this meeting and any corrections or additions needed to be made to the published list of members, and to distribute copies of the same to all members. He was also instructed to secure and distribute to members reprints of the proceedings of the Philadelphia meetings when the same shall have been published in SCIENCE.

The committee on premedical education, appointed at the last annual meeting, submitted no report and it was continued with instructions to report at the annual meeting in 1915.

The executive committee, to which the "Matthews Plan for the Organization of an American Biological Society" was referred last year for consideration and report to a future meeting, asked and was granted more time for this work.

The question of holding a mid-year meeting of the society, as a whole, in San Francisco in connection with the Panama Exposition was considered and, upon motion by Professor R. G. Harrison, the society took the following action: "The American Society of Zoologists urges its members who reside on the Pacific coast to form a section of the society, such as is provided for by the constitution, and that this section cooperate in organizing and holding a zoological meeting in San Francisco in connection with the Panama Exposition, and it assures these members of the sincere interest and approval of the society in such an undertaking."

A committee on resolutions on the death of Professor Charles Sedgwick Minot and Professor Seth Eugene Meek, consisting of Professors Frank R. Lillie, R. G. Harrison and H. V. Neal, was appointed and instructed to prepare resolutions and publish the same in SCIENCE and to transmit copies to the families of the deceased members.

The secretary-treasurer submitted the following financial statement which, having been examined and found correct by the auditing committee, consisting of Professors A. S. Pearse and E. A. Budington, was accepted by the society.

Receipts

1914		
Jan. 1	Balance on hand (Eastern Branch)	\$361.71
18	Received from Treasurer Central Branch	235.51
	Received during the year annual dues from members	247.03
Feb. 14	Received first dividend from the Permanent Fund from the Custodian, J. H. Gerould	22.50
Oct. 13	Received interest on Current Funds on deposit with the Title, Guarantee and Trust Co., Baltimore	23.58
Nov. 11	Received second dividend from the Permanent Fund from Custodian, J. H. Gerould	15.00
	Total receipts	\$905.33

Expenditures

Jan. 3	for "Smoker" supplies	\$19.00
14	for circular letter to new members	1.40
22	for typewriting by-laws for executive committee	1.75
26	for stamps for mailing the above50
26	for blanks forms for addresses, etc., of members	1.15
28	for express on MSS. of Proceedings to Science25
29	for typewriting circular letter to executive committee00
29	for express on "files" from Secretary, Central Branch	1.00
Feb. 6	for 1,000 special stamped (2 c.) envelopes	21.36
11	for I. P. Binder and two packages Journal sheets	2.25
28	for stamps	1.50
Mch. 31	for addressing and mailing due bills and circular letters	2.55
Apr. 13	for new journal50
May 30	for multigraphing blank forms	1.50
June 6	for typewriting constitution, by-laws, list of members	5.85
17	for express on files, typewriter and MSS. to Woods Hole	1.60
Sept. 17	for express on MSS. of List of Members to printer22
Oct. 1	for express of files and typewriter, Woods Hole to Baltimore	1.80
24	for 500 copies printed constitution, by-laws, list of members, etc.	75.00
26	for 500 Columbia Clap envelopes	3.50
26	for 500 copies printed blanks for nominations of new members	0.75

26	for mailing copies of Constitution, etc.	7.46
Nov. 4	for 300 copies announcement of Philadelphia meeting	3.25
4	for mailing announcements to members	1.50
Dec. 4	for 300 copies "Preliminary Program"	18.16
12	for mailing preliminary programs and map to members	3.85
18	for 280 special stamped (1 c.) envelopes	3.09
26	for 500 printed programs for the annual meeting	10.40
26	for 500 sheets typewriter paper	1.90
28	for R.R. fare of secretary to Philadelphia and return	4.90
30	for expense incurred by the Secretary in attending the annual meeting	16.00
	Total expenditures	\$216.18
	Total receipts	\$905.33
Dec. 30	Balance on hand	\$689.15

At sessions held during the forenoon and afternoons of December 29 and 30 the following papers were read either in full or by title:

In order to complete the program by the end of the fourth session and thus clear the way for adjournment to attend the session of the Naturalists scheduled for the forenoon of December 31, it was found necessary to provide for the simultaneous meeting of two sections of the Zoologists during the afternoon of December 30. At one of these sectional meetings papers grouped under *General Physiology* and some under *Miscellaneous* were read, and those under *Ecology* and the remaining *Miscellaneous* papers were read at the other. For the same reason practically no time was taken at any session for the discussion of facts and conclusions presented.

Comparative Anatomy

Nerve and Plasmodesma: H. V. NIEL. (With lantern.)

The present paper, based upon observations upon *Squalus* embryos preserved by the Bielchowsky-Paton method, attempts to give an answer to three controverted problems in nerve histogenesis:

1. Are connections between tube and myotome primary or secondary?

2. Are neuromuscular connections primarily undifferentiated plasmodesmata or are they primarily neurofibrillar?

3. Are neuromuscular connections effected by indifferent-neurilemma-cells or by medullary neuroblasts?

The answers given to these questions are:

1. Previous to the stage of 4.5 mm. there are no protoplasmic connections between tube and myotome in *Squalus* embryos.

2. Neurofibrillar substance is present in the first protoplasmic connections between tube and myotome. In the primary protoplasmic connections appear deeply staining neurofibrils which may be traced to bipolar neuroblasts within the neural tube. The claim that the primary connections consist of undifferentiated plasmodesmata therefore is based upon inadequate neurological methods.

3. In stages before protoplasmic connection between tube and myotome is effected certain medullary cells in zones where later the nerve anlagen make their appearance show in Bielchowsky-Paton preparations a deeply-staining neuro-reticulum. In slightly later stages when neuro-muscular connection is established similar neuro-reticular cells are found connected with neurofibrils extending into the nerve anlagen in the manner characteristic of medullary neuroblasts stained by specific neuro-fibrillar stains. The evidence of the presence of similar neurofibrillar substance in all parts of the nerve anlagen supports the inference that the neuromuscular connections are established—not by indifferent cells—but by medullary neuroblasts, as maintained by supporters of the Bidder-Kupffer theory. Indifferent cells participate in the formation of nerve anlagen only in more advanced stages by a process of migration from the neural tube.

The Components of the Fenestral Plate in Neoturus: H. D. REED.

In previous communications it has been pointed out that in certain urodele families the sound-transmitting apparatus consists of a single piece resulting from gradual growth during larval and early adult life. In such forms the plate is compound. The stylus represents columella or the extracotic element, while the plate itself arises from chondrification within the fenestral membrane and therefore otic in nature.

The fenestral plate in *Neoturus* has been considered as *columella*. It arises outside the ear capsule and gradually comes to lie against the fenestral membrane over the cephalic portion of which it spreads through growth eventually filling the fenestra at this level. Caudad the plate tapers coming to a point at about the middle of the fenestra. The plate thus formed is soon encased in bone. About the margin of this triangular columellar plate cartilage is formed by

chondroblasts which arise in the fenestral membrane. The matrix which is soon secreted is invaded by bone deposited in continuity with the previously formed bony case. Thus cell by cell the definitive structure is completed by additions to the margin of the columellar plate. The fenestral plate is to be considered, therefore, as a compound structure possessing both otic and extraotic elements and must be looked upon as a morphology intermediate of the condition found in *Ambystoma* and the *Plethodontidae*.

Variations in the Rays of Ten Thousand Star-Fish, Asterias Forbesii: FRANKLIN D. BARKER. (With lantern.)

A New Dignetic Trematode from the Crayfish: JOHN W. SCOTT.

In 1827 Von Baer described a fluke from the crayfish to which he gave the name *Distomum cirrigerum*. Warren ('03) described its anatomy and development, and Sulowioff ('11) discussed its structure and systematic position. During the past two years trematodes from American crayfish have been secured; these are all encysted, sexually mature, individuals. In certain points they are quite similar to the European form, but the differences are so striking as to place them in different species. Wright ('84) appears to have been the first to observe the fluke in this country, but mistook it for *D. nodulosum*. Linton ('92) gives a brief description of immature specimens, and calls attention to Wright's mistake. The American species differs from the European in the following particulars. It has no conical or plate-like cuticular scales; it has two lateral palp-like extensions of the oral sucker, and four papillae; the esophagus is short, the gastric coeca arising in front of the genital pit; the yolk glands extend nearer the anterior end of the body; both testes are median, or nearly so, and one lies in front of the other; small cuticular denticles are found on the oral sucker; the cerebral ganglia are wider apart, the prostate gland better developed, and the excretory bladder of somewhat different shape.

A full description of the new form, with a discussion of its probable systematic relationship, will soon be published.

The Reflex "Bleeding" of the Coccinellid Beetle, Epilachna borealis: N. E. McINDOO.

The Gland of the Clasper in Sharks: E. W. GUDGER.

In the claspers of sharks, on the inner and dorsal surface the tissues are modified to form a

groove. This is continued forward between the skin and the pelvic arch where it enlarges to form a sac, which in its turn is extended forward as a tube between the skin and the belly wall. Each tube ends blindly near the median line, in some extending nearly to the pectoral girdle. The function of this organ is entirely unknown.

These structures were described from *Hypoprion brevirostris* and *signatus*, and from the tiger shark, *Galeorhinus tigrinus* captured at Key West and at Tortugas, Florida. The longest gland (one foot, 7½ inches) was found in a 4 foot, 10 inch specimen of *H. signatus*.

The scanty literature of this organ from its discovery by Andrew Smith in 1849 was briefly sketched. The full data will be given later in an article in "Papers from the Tortugas Laboratory," published by the Carnegie Institution of Washington.

Pre-otic Somites in Cyclostomes: H. V. NEAL.
(With lantern.)

Concerning no other criterion of the metamorphism of the vertebrate head do observations so fully agree as with regard to the mesodermic divisions discovered by Van Wijhe ('82) in Selachian embryos. His discovery has been confirmed by Miss Platt ('91), Hoffman ('94), Neal ('96), Sowerzoff ('98), Braus ('99) and Johnston ('09). Moreover, Sowerzoff showed that the more numerous "microcoelic" divisions described by Dohrn ('90) and Killian ('91) in *Torpedo* embryos secondarily unite to form the somites of Van Wijhe. Furthermore, a mesodermic segmentation which may be compared with that of Elasmobranchs has been discovered by Miss Platt ('97) in Amphibia and by Koltzoff ('02) in Cyclostomes.

The mesodermic segmentation discovered by Koltzoff ('01) in *Petromyzon* embryos is especially significant and important, since in this animal according to Koltzoff the segmentation of the head mesoderm is complete as in *Amphioxus* and the somites develop as dorso-lateral diverticula of the endoderm. Thus *Petromyzon* is in this respect as in others intermediate between *Acrania* and *Gnathostomata*. Koltzoff finds that the three anteriormost somites give rise to the eye muscles as they do in the Elasmobranchs.

The importance of the evidence as bearing on the past history of the vertebrate head has led me to examine sections of *Petromyzon* embryos in the hope of confirming Koltzoff's results. In at least two series of eight-day *Petromyzon planeri* am-

bryos the evidence presented seems to bear out Koltzoff's contention that the pre-otic segmentation of the mesoderm is comparable with that of Elasmobranch embryos. The anterior head mesoderm is completely segmented as Koltzoff has asserted. No homologue of Miss Platt's "anterior" somites, however, is present in the Cyclostome.

The Absence of Male Reproductive Organs in Trematodes: FRANKLIN D. BARKER. (Lantern slides and demonstrations.)

Does Amphioxus Eat with His Left Ear?: H. V. NEAL. (With lantern.)

It was Van Wijhe ('93) who first suggested the homology of the larval mouth of *Amphioxus* with the left spiracle of Selachians and asserted that "Amphioxus can not hear; he eats with his left ear and consequently has lost his mouth." The homologue of the craniote mouth in *Amphioxus* is, according to Van Wijhe, the pre-oral pit.

The present paper raises the problem: Are we to accept the homology of the mouth of *Amphioxus* with the spiracular cleft of Craniotes?

The homology suggested by Van Wijhe is based on the following grounds:

1. The mouth of *Amphioxus* is an organ of the left side as evidenced by its development, its left-sided innervation and its topographic relations to the club-shaped gland, which Van Wijhe regards as the antimeric gill-pouch.

2. The relations of the larval mouth of *Amphioxus* to the second mesodermic cavity and to the splanchnic muscles derived from it are similar to those of the left spiracle of Craniotes to the second mesodermic head-cavity.

Van Wijhe's homology may not be accepted on the following grounds:

1. Since all median openings of *Amphioxus* are asymmetrically displaced, the left-sided position of the mouth is not significant.

2. The left-sided innervation is likewise incisive. If the homology suggested by Van Wijhe were the correct one, the velum should be innervated by the left nerve of the third pair. It is actually innervated by the left nerves of the 4-7 pairs. Primary nerve relations are obviously disturbed and inferences from innervation precarious.

3. The club-shaped gland and its duct represents a pair of gill-pouches and not a gill-pouch of the right side only, as Van Wijhe's homology would require. The club-shaped gland represents the second pair of gill-pouches and the endostyle anlage the first pair of gill-pouches of *Amphioxus*.

4. The chief objection to the homology maintained by Van Wijhe is the fact that the anterior endodermic diverticula of *Amphioxus* are homologous—not with the pre-mandibular head cavities of Elasmobranchs as assumed by Van Wijhe—but with the "anterior" head cavities. The homologues of the pre-mandibular cavities of Elasmobranchs (the first permanent myotomes) are the first permanent myotomes of *Amphioxus*.

Amphioxus does not eat with his left ear. The homologue of the left spiracle is the first transient gill cleft of *Amphioxus*. The mouth of *Amphioxus*, however, is not homologous with the mouth of *Craniotes*. If it is homologous with any organ of the *Craniotes*, that organ is the hypophysis.

Embryology

Internal Factors Producing the Swarming of the Atlantic Palolo: AARON L. TREADWELL.

Previous explanations of the swarming of annelids have been based on the influence of the external factors such as light, tidal pressure, etc. At the Carnegie Laboratory in the Dry Tortugas I was able with the cooperation of Dr. Tashiro to test the hypothesis that an internal factor co-operates in producing this effect. Since all the eggs of the Atlantic palolo are laid at one definite time, it is possible to test the eggs at any desired interval before the time when they would normally be laid. Testing with his biometer, Dr. Tashiro found that five days before laying each egg gave off 0.000,000,07 grams of CO₂ per minute; two days before laying 0.000,000,083 grams, while eggs taken from the body of a swarming female were eliminating 0.000,000,13 grams per minute. All eggs were taken from the body without mixture with sea water. This indicates an increase in metabolic activity as the time of swarming approaches, and the conclusion follows that this furnishes an internal stimulus of importance in producing the swarm. Probably a similar stimulus is operative in ordinary egg laying.

Are the Taste-buds of Elasmobranchs Endodermal in Origin? MARGARET H. COOK. (Introduced by H. V. Neal.)

An attempt to determine the origin, whether ectodermal or endodermal, of taste-buds in *Squalus acanthias*. A study was made of sections of embryos of 7 to 80 mm. supplemented by dissections of "pup" and adult stages.

Taste-buds in this species are limited to the region of the pharynx, which in all stages of ontogeny is lined with endoderm. No marked en-

croachment of the ectoderm is perceptible even in the mouth region.

Scales similar to those which characterize the outer skin arise in late stages of ontogeny in both the floor and roof of the pharynx. Thus two kinds of organs usually classed as ectodermal, viz., taste-buds and placoid scales, appear to arise from the endoderm of the pharynx of *Squalus acanthias*. To assert that the pharyngeal taste-buds and scales of *Squalus* are ectodermal would necessitate the assumption that the endodermic lining of the pharynx completely disappears during ontogeny and is replaced by ectoderm. Evidence of such substitution is wholly lacking.

These results extend to the Elasmobranchs the conclusion of Johnston ('98 and '10) that the taste-buds of Teleosts and Amphibia are derived from endoderm. They also add to the structures derived from the endoderm the pharyngeal scales which have hitherto been assumed to be ectodermal, and thus add another exception to the law of the specificity of the germ-layers.

*On the Larval and Post-larval Development of the Coral, *Agaricia Fragilis*, Dana:* J. W. MAYOR. (With lantern.) (Introduced by E. L. Mark.)

Tissue and Organ; Their Roles in Morphogenesis: HERBERT W. RAND.

Definiteness of form is the essential characteristic of an organ. Tissue is without form. Our attempt to discover the factors immediately responsible for the form of an organism will be furthered if we clearly distinguish the parts played by organic units of the several grades. How far does a given formative event depend upon cells acting as uncoordinated individuals, how far does it depend upon a system of cells co-ordinated into a tissue, and how far does it exhibit the impress of organization higher than that of tissue?

In the wound-closing activities of tentacles of actinians, cells, as such, play a minor and probably unessential part. The definitive structural closure is an autonomous tissue process. Accompanying activities of the neuro-muscular complex afford temporary protection and favor the carrying out of the tissue process. In these activities and in other reactions of the neuro-muscular complex, we observe polarity and a variety of definite relations to the form of the organism. These bespeak for the neuro-muscular complex a degree of organization higher than that of mere tissue, probably corresponding to the organism as a whole.

The neuro-muscular complex may be regarded as standing at a threshold of organization. Morphologically standing at the level of a tissue, it exhibits the physiological definiteness and differentiation which characterize an organ. Thus, in a sense, function anticipates structure.

(Based upon a paper now in press in *Archiv für Entwicklungsmechanik der Organismen*.)

The Form of the Stomach in Embryos of the Cat, Albino Rat, Pig and Sheep: CHESTER H. HEUSER.

Utero-gestation in the Sheep-nosed Shark, Scollion Terranova: E. W. DUDGER.

In a 37½-inch specimen with a girth of 13½ inches taken at Tortugas, Florida, the left ovary was twice as long as the non-functional left lobe, while the oviducal apparatus was paired, symmetrical, and had both sides functional. The eggs, each enclosed in a thin yellow shell with its long pointed ends curiously folded and plaited, lay in crypt-like lateral "nests" formed in the mucous lining of the uteri. The structure of the uterus and the formation of the "nests," with the relation thereto of the curious shells, were described and illustrated, as were also the young and their connection with the yolk and finally with the uterine wall. In all respects the eggs and their shells together with the uteri containing them are in close parallel with similar structures in the bonnet-head shark, *Sphyrna tiburo*, reported on by the speaker at the Princeton meeting of the society in 1911.

An article giving all the data at hand and illustrated by photographs will appear later in "Papers from the Tortugas Laboratory" of the Carnegie Institution of Washington.

Experimentally Fused Larvae, with Special Reference to Changes in Polarity, Symmetry, Synchronicity, Etc.: A. J. GOLDFARB.

Experiments in Cleavage: T. S. PAINTER. (Introduced by R. G. Harrison.)

Cytology

A Study of the Maturation Period in the American and European Molecrickets: F. PAYNE.

Regenerative Potencies of Dissociated Cells of Hydromedusae: CHARLES W. HADGITT.

The paper describes experiments made at the Zoological Station, Naples, several years ago. About a dozen species of hydroids, and one species of medusa were experimented on, and with

results which in the main confirm those of H. V. Wilson, published since my own were made. The paper also briefly reviews a series of similar experiments made by DeMorgan and Drew.¹ These latter experiments are the immediate occasion for giving publicity to my own work, as they appear to imply some doubt as to the conclusiveness of Wilson's work. Their experiments were made upon two species of *Antennularia*, and while serving to confirm earlier phases of those of Wilson they never gave rise to new hydranths. The authors declare "our experiments have resulted in the production of masses that are certainly abnormal and pathological, but nevertheless we would submit that the segregation and rearrangement of the cells after isolation, and the considerably long duration of life of the tumor-like masses to which they give rise, are facts of considerable theoretical interest."

The paper will show that the assumption as to the abnormality and pathological conditions apparent are not warranted by the more extended knowledge of facts from these and other sources. Indeed, many facts concerning the behavior of these organisms in development and regeneration seem to prove that fundamentally there is neither abnormality nor pathological process involved.

Microdissection Studies on the Physical Properties and Behavior of Cell Structures, Especially in Orthopteran Spermatogenesis: ROBERT CHAMBERS, JR.

Cells studied were of Orthopteran gonads, plant-root tips and pancreas of frog. Fresh material corroborates in many interesting details nuclear structures observed in fixed material. Mitochondria and the cytoplasm, however, largely show artifacts with fixatives.

Puncture of a cell by a needle generally causes irreparable injury. Slight injury hastens the normal reversible changes in the physical states of the colloids in the cell, but soon transforms them to an abnormal condition which leads to death.

Injury to the cell is followed by swelling accompanied by an increased imbibition of water.

Physiological salt solutions are more or less injurious to cells normally bathed in organic fluids.

A tension exists in the cell during division which is lost when any part of the cell is torn. Janus green (Hoechst) stains mitochondria rapidly. In the nucleus it is reduced to safranin, which kills the cell.

¹ *Jour. Marine Biol. Assoc.*, Plymouth, October, 1914.

Janus green produces coagulation phenomena in living protoplasm and therefore should not be used to identify mitochondria.

The mitochondria are rigid structures. In the Orthopteran germ they all change from granules to strands, they coalesce, they disappear and reappear and may be expressions of changes in the physical states of the cytoplasmic colloids.

The chromosomes behave almost as do the mitochondria. In the hyaline resting nucleus they appear in the form of granules ranged about a hyaline resistant core. The granules coalesce to form the homogeneous body of the metaphase chromosomes. In telophase the chromosomes swell and disappear. Some internal chemical condition may exist which so regulates the physical states of the nuclear colloids that a constant number of chromosomes periodically appears.

Spermatogenesis in Paratettix: MARY T. HARMAN.

1. The chromosomal complex of the spermatogonial divisions of *Paratettix leuconotus*—*leucothorax* consists of thirteen rod-shaped chromosomes which may be divided into two groups, one consisting of four large chromosomes and the other of nine smaller ones.

2. Eight of the smaller chromosomes are straight rods; one of the smaller ones and all of the larger ones are U-shaped. The chromosomes do not form equal pairs.

3. In the metaphase stage the chromosomes are at right angles to the spindle fibers, but in the anaphase they are parallel to them.

4. One chromosome is always far to the center of the spindle. Sometimes it is completely surrounded by the others and sometimes merely one end is at the center of the spindle. It is never the bent chromosome but is always one of the larger ones of the group of nine.

5. In the early prophase is always a mass of chromatin which never takes on the reticular condition, but has a more compact consistency and stains more intensely than the remainder of the chromatin material.

6. At the beginning of the growth period the nucleus becomes large, and some of the chromatin takes on the reticular condition and stains lightly, but there is one mass that is compact, stains intensely and has the appearance of a nucleolus. It forms the accessory chromosome.

7. In synizesis there is no polarization of the chromatin thread.

8. In the primary spermatocyte are always six

dumb-bell-shaped chromosomes but two are much larger than the others.

9. The first spermatocyte division is always a cross division. The accessory chromosome always lies near the periphery of the spindle and passes to one pole undivided much in advance of the others.

10. All the chromosomes divide in the second spermatocyte division.

Synapsis and the Individuality of the Chromosomes: D. H. WENRICH.

In attempting to determine whether synapsis in this Acridid grasshopper is end-to-end (telosynapsis) or side-by-side (parasynapsis), it was found that the only method by which conclusive evidence could be obtained was that of following the history of individual chromosomes.

Of the 12 haploid chromosomes present in this species, at least three were found to possess individual peculiarities by which they could be recognized throughout the growth period and the pro-phases of the first maturation division.

Parallel conjugation of the fine spireme threads of the early growth stages appeared to occur as a general rule, and different steps in the process could be followed for at least one of the differential chromosomes. Conjugation did not result in loss of identity of the uniting threads in the sense of forming "mixochromosomes," for the plane of separation between them remained visible throughout the spireme stages. However, pairs of granules often appeared to be fused into single ones. Spireme segments separate out as rods or loops with a single split, tetrads being formed by a second longitudinal split at right angles to the one already present.

Analysis of the spireme stages of one of the differential chromosomes revealed a series of granules (chromosomes) along its length, such that the relative size and position of the granules were constant not only in the cells of one individual, but in those of all the animals studied.

Chromosomes with peculiarities analogous to those found in the first spermatocyte could be recognized in the spermatogonia.

In the first maturation division the monosome passes to one pole undivided. The tetrads appear to divide equationally with one exception. In this tetrad the conjugants are very unequal and division is as often reductional as equational. When dividing reductionally the unequal dyads show, with reference to the monosome, a distribution according to the law of chance (Mendel's law).

The Orientation of the Nuclear Contents in the Motor Electric Cells of Torpedos: ULRIC DAHLGREN. (With lantern.)

The nucleus contains, besides the usual chromatin bodies, a large typical plasmosome and a somewhat smaller body, the para-nucleolus. These two are always oriented in a dorso-ventral position and the cause of this orientation was sought in either the electric current that passes through the tissue or in the influence of gravity. Electric currents of the same strength as those generated by the fish and when applied at right angles to or directly against the orientation in question failed to influence it even when applied for several hours. Stronger currents moved the nuclear contents, but also changed the structure and chemical composition of the parts. One fact seemed to be shown; that the plasmosome was not moved to either pole of the nucleus, but assumed a position between two materials that did occupy the two halves of the nucleus.

Gravity experiments were interesting and seemed to solve the question; at a lower rate of centrifugal force the plasmosome was moved to the side of the nucleus away from the force. At a higher rate the chromatin bodies were also moved, while with the greatest force used the para-nucleus was also moved. The Naples torpedos possess no parannucleolus in these cells.

Genetics

Bristle Inheritance in Drosophila: E. CARLETON MACDOWELL. (With lantern.)

A race of *Drosophila ampelophila* has been established from wild flies that has extra thoracic bristles. Crosses with normal flies prove that the extra bristled condition is a recessive Mendelian character. The number of extra bristles that appear in this race varies. The first six generations from parents selected for increase in bristle number showed a steady rise in the numbers of bristles. For thirteen generations after this, selection was apparently ineffective.

Three interpretations of successful selection may be examined.

1. Determiners may be inconstant; higher grades of a character have higher grade determiners. This would not account for the thirteen generations of ineffective selection, nor the genetic uniformity in the later generations which is evidenced by, (a) high and low grade parents from the same family giving like offspring, (b) analysis of high and low grades by crosses, (c) absence of

correlation between means of parents and offspring in whole generations after the sixth.

2. Selection may produce a more vigorous line, and this vigor may occasion the better development of the character. A large fly in the extra race is apt to have more bristles than a small one.

3. Multiple factors may exist which are reduced to a homozygous condition by selection. Extracted extra bristles have a lower distribution than the uncrossed extras, yet the high extremes of the selected race are equalled. This would be the result if selection had removed some accessory restricting genes. These facts do not agree with the second interpretation, whereas all observations are in accord with the third interpretation.

The Behavior of a Unit Character in the Grouse Locust, Paratettix: ROBERT K. NABOURS.

Size Dimorphism in the Spermatozoa and Its Relation to the Chromosomes: CHARLES ZELENY AND E. C. FAUST.

Further evidence has been obtained in favor of the view that the size dimorphism of the spermatozoa observed in several species by the authors is correlated with the chromosomal dimorphism of the spermatids. The ratio between the chromosomal volumes was calculated from published figures of the spermatogenesis in the three species, *Musca domestica*, *Alydus pilosulus* and *Anasa tristis*. From this ratio the expected ratio between the head lengths in the resulting spermatozoa was calculated on the assumption that the size of the heads is directly proportional to the amount of chromatin received and on the further assumption that the shape of the heads is the same for all sizes. The calculated ratios and the corresponding observed ratios are as follows: *Alydus pilosulus*, calculated 1.00:1.08, observed 1.00:1.055; *Musca domestica*, calculated 1.00:1.08, observed 1.00:1.07; *Anasa tristis*, calculated 1.00:1.11, observed 1.00:1.09. Complete data were given in the February, 1915, number of the *Journal of Experimental Zoology*.

Sex Controlled by Food Conditions in Hydatina Senta: DAVID D. WHITNEY.

The cause of the erratic proportion of the two sexes in *Hydatina senta* has been found to be due to diet. When three pedigreed parthenogenetic races of these rotifers were reared in the laboratory on a constant and uniform diet of a colorless flagellate, *Polytoma*, through 181-288 generations in 14-22 months they produced 96 per cent. to 100

per cent. of female grandchildren, thus showing that uniform food conditions cause nearly all females to be produced. However, when these rotifers that were producing almost exclusively female grandchildren on a uniform diet were suddenly put upon a new diet of the green flagellate, *Chlamydomonas*, they almost ceased producing female grandchildren and produced as high as 83 per cent. of male grandchildren. Moreover, if the first few eggs of each female that were laid in the *Chlamydomonas* diet were discarded all the grandchildren were males, thus showing that a sudden change from a uniform diet to a new diet causes the total suppression of nearly all females and the production of nearly all males.

Parthenogenesis and Sex in Anthothrips Verbasci:
A. FRANKLIN SHULL.

The life cycle of few species of *Thysanoptera* is definitely and completely known. In general, sexual reproduction has been inferred in species having abundant males, especially if mating has been observed in nature. Such a species is *Anthothrips verbasci*, the mullein thrips. However, adult females reared in isolation from pupae, and placed on thrips-free plants, have given rise to offspring. These offspring must have been produced parthenogenetically. It is not safe, therefore, to infer merely from the abundance of males or the occurrence of copulation, that any species is sexual. Whether *Anthothrips verbasci* exhibits both parthenogenetic and sexual reproduction has not yet been determined.

Twenty-eight of the parthenogenetically produced young have reached stages sufficiently advanced to allow their sex to be recognized. All were males. This suggests that the same relation exists between parthenogenesis and sex as in the honey bee and some other Hymenoptera, though other explanations are obviously possible.

Sex Control and Known Correlations in Pigeons:
OSCAR RIDDLE.

Some Internal Factors Influencing Egg Production in the Rhode Island Red Breeds of Domestic Fowl: H. D. GOODALE.

Multiple Human Births: G. H. PARKER.

A Note on the Origin of a Color Variety of Mice:
CLARENCE C. LITTLE.

A Modification of the Agouti Factor in a Cavy Species Cross: J. A. DETLEFSEN. (Introduced by W. E. Castle.)

The agouti character of the wild Brazilian cavy, *Cavia rufescens*, acts as a single unit in heredity, when transmitted to hybrids between this species

and the tame species, *C. porcellus*. This unit character, however, is often modified in the hybrids. The modification is essentially a weakening in the power to restrict black and brown pigments from the sub-apical portion of the hair. The weakened modified agouti character of the hybrids was found to be a recessive in crosses with the normal agouti guinea-pig. The normal agouti of the tame guinea-pig, the modified agouti of the hybrids, and non-agouti, are triple-allelomorphs.

The Effects of Long-continued Parthenogenetic Reproduction (127 Generations) upon Daphnia: A. M. BANTA.

The writer has kept pure lines of *Daphnia pulex* reproducing continuously by parthenogenesis alone for over three years. Some of the lines have now reached the 127th generation. If the sexual cycle is a necessary and essential feature of reproduction in this species the fact should ultimately become evident in the reduced vigor in the parthenogenetic lines. In order to discover if any reduction in vigor had actually occurred some "wild" *Daphnia pulex* were obtained from out-door ponds. These "wild" lines were treated in every way identically (except that no selection was made with them as with the older lines) with the lines already under observation. The age of the mother at the time her first brood appeared, the number of individuals in the first brood and the interval until a second brood was produced were taken as measures of the vigor of the individual. Average values obtained from large numbers of mothers of the "wild" lines and of the selection lines constituted the data finally obtained.

Measured by these standards, the lines reproducing parthenogenetically from the 70th to the 92d generation under laboratory conditions possessed somewhat less vigor than wild lines descending from the 1st to the 23d generation under laboratory conditions. During the summer (1914) food conditions were quite unfavorable. "Wild" lines descending from the 2d to the 9th generation showed a marked superiority in vigor as compared with the lines which during the same descended from the 98th to the 103d generation. However on the return of normally favorable food conditions the lines long reproducing parthenogenetically under laboratory conditions actually on each of the three points of comparison appeared to have a superiority of vigor.

GRADUATE MATHEMATICAL INSTRUCTION FOR GRADUATE STUDENTS NOT INTENDING TO BECOME MATHEMATICIANS¹

IN his "Annual Report" under date of November last, the President of Columbia University speaks in vigorous terms of what he believes to be the increasing failure of present-day advanced instruction to fulfill one of the chief purposes for which institutions of higher learning are established and maintained.

President Butler, in the course of an interesting section devoted to college and university teaching, says:

A matter that is closely related to poor teaching is found in the growing tendency of colleges and universities to vocationalize all their instruction. A given department will plan all its courses of instruction solely from the point of view of the student who is going to specialize in that field. It is increasingly difficult for those who have the very proper desire to gain some real knowledge of a given topic without intending to become specialists in it. A university department is not well organized and is not doing its duty until it establishes and maintains at least one strong substantial university course designed primarily for students of maturity and power, which course will be an end in itself and will present to those who take it a general view of the subject-matter of a designated field of knowledge, its methods, its literature and its results. It should be possible for an advanced student specializing in some other field to gain a general knowledge of physical problems and processes without becoming a physicist; or a general knowledge of chemical problems and processes without becoming a chemist; or a general knowledge of zoological problems and processes without becoming a zoologist; or a general

¹MSB. Intended for publication and books, etc., intended for review should be sent to Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

¹ An address delivered before Section A of the American Association for the Advancement of Science, December 30, 1914.

knowledge of mathematical problems and processes without becoming a mathematician.

This is a large matter, involving all the cardinal divisions of knowledge. I have neither time nor competence to deal with it fully or explicitly in all its bearings. As indicated by the title of this address it is my intention to confine myself, not indeed exclusively but in the main, to consideration of the question in its relation to advanced instruction in mathematics. The obvious advantages of this restriction will not, I believe, be counterbalanced by equal disadvantages. For, much as the principal subjects of university instruction differ among themselves, it is yet true that as instruments of education they have a common character and for their efficacy as such depend fundamentally upon the same educational principles. A discussion, therefore, of an important and representative part of the general question will naturally derive no little of whatever interest and value it may have from its implicit bearing upon the whole. It is not indeed my intention to depend solely upon such implicit bearings nor upon the representative character of mathematics to intimate my opinion respecting the question in its relation to other subjects. On the contrary, I am going to assume that specialists in other fields will allow me, as a lay neighbor fairly inclined to minding his own affairs, the privilege of some quite explicit preliminary remarks upon the larger question.

I suspect that my interest in the matter is in a measure temperamental; and my conviction in the premises, though it is not, I believe, an unreasoned one, may be somewhat colored by inborn predilection. At all events I own that a good many years of devotion to one field of knowledge has not destroyed in me a certain fondness for avocational studies, for books that deal with large subjects in large ways, and for men who, uniting the generalist with the spe-

cialist in a single gigantic personality, can show you perspectives, contours and reliefs, a great subject or a great doctrine in its principal aspects, in its continental bearings, without first compelling you to survey it pebble by pebble and inch by inch. I can not remember the time when it did not seem to me to be the very first obligation of universities to cherish instruction of the kind that is given and received in the avocational as distinguished from the vocational spirit—the kind of instruction that has for its aim, not action but understanding, not utilities but ideas, not efficiency but enlightenment, not prosperity but magnanimity. For without intelligence and magnanimity—without light and soul—no form of being can be noble and every species of conduct is but a kind of blundering in the night. I could hardly say more explicitly that I agree heartily and entirely with the main contention of President Butler's pronouncement. Indeed I should go a step further than he has gone. He has said that a university *department* is not well organized and is not doing its duty until it establishes and maintains the kind of instruction I have tried to characterize. To that statement I venture to add explicitly—what is of course implicit in it—that a *university* is not well organized and is not doing *its* duty until it makes provision whereby the various departments are enabled to foster the kind of instruction we are talking about. That in all major subjects of university instruction there ought to be given *courses* designed for students of "maturity and power" who, whilst specializing in one subject or one field, desire to generalize in others, appears to me to be from every point of view so reasonable and just a proposition that it would not occur to me to regard it as questionable or debatable were it not for the fact that it actually is questioned and debated by teachers of eminence and authority.

What is there in the contention about which men may differ? Dr. Butler has said that there is a "growing tendency of college and university departments to vocationalize all their instruction." Is the statement erroneous? It may, I think, be questioned whether the tendency is growing. I hope it is not. Of course specialization is not a new thing in the world. It is far older than history. Let it be granted that it is here to stay, for it is indispensable to the advancement of knowledge and to the conduct of human affairs. Every one knows that. There is, however, some evidence that specialization is becoming, indeed that it has become, wiser, less exclusive, more temperate. The symptoms of what not long ago promised to become a kind of specialism mania appear to be somewhat less pronounced. Recognition of the fact that specialization is in constant peril of becoming so minute and narrow as to defeat its own ends is now a commonplace among specialists themselves, many of whom have learned the lesson through sad experience, others from observation. Specialists are discoverers. One of our recent discoveries is the discovery of a very old truth: we have discovered that no work can be really great which does not contain some element or touch of the universal, and that is not exactly a new insight. Leonardo da Vinci says:

We may frankly admit that certain people deceive themselves who apply the title "a good master" to a painter who can only do the head or the figure well. Surely it is no great achievement if by studying one thing only during his whole lifetime he attain to some degree of excellence therein!

The conviction seems to be gaining ground that in the republic of learning the ideal citizen is neither the ignorant specialist, however profound he may be, nor the shallow generalist, however wide the range of his interest and enlightenment. It is not important, however, in this connection

to ascertain whether the vocationalizing tendency is at present increasing or decreasing or stationary. What is important is to recognize the fact that the tendency, be it waxing or waning, actually exists, and that it operates in such strength as practically to exclude all provision for the student who, if I may so express it, would qualify himself to gaze into the heavens intelligently without having to pursue courses designed for none but such as would emulate a Newton or a Laplace. If any one doubts that such is the actual state of the case, the remedy is very simple: let him choose at random a dozen or a score of the principal universities and examine their bulletins of instruction in the major fields of knowledge.

Another element—an extremely important element—of President Butler's contention is present in the form of a double assumption: it is assumed that in any university community there are serious and capable students whose primary aim is indeed the winning of mastery in a chosen field of knowledge but who at the same time desire to gain some understanding of other fields—some intelligence of their enterprises, their genius, their methods and their achievements; it is further assumed that this non-vocational or avocational propensity is legitimate and laudable. Are the assumptions correct? The latter one involves a question of values and will be dealt with presently. In respect of the former we have to do with what mathematicians call an existence theorem: Do the students described exist? They do. Can the fact be demonstrated—deductively proved? It can not. How, then, may we know it to be true? The answer is: partly by observation, partly by experience, partly by inference and partly by being candid with ourselves. Who is there among us that is unwilling to admit that he himself now is or at least once was a student of the kind?

Where is the university professor to whom such students have not revealed themselves as such in conversation? Who is it that has not learned of their existence through the testimony of others? No doubt some of us not only have known students of the kind, but have tried in a measure to serve them. We may as well be frank. I have myself for some years offered in my subject a course designed in large part for students having no vocational interest in mathematics. I may be permitted to say, for what the testimony may be worth, that the response has been good. The attendance has been composed about equally of students who were not looking forward to a career in mathematics and of students who were. And this leads me to say, in passing, that, if the latter students were asked to explain what value such instruction could have for them, they would probably answer that it served to give them some knowledge *about* a great subject which they could hardly hope to acquire from courses designed solely to give knowledge *of* the subject. Every one knows that it often is of great advantage to treat a subject as an object. One of the chief values of n -dimensional geometry is that it enables us to contemplate ordinary space from the outside, as even those who have but little imagination can contemplate a plane because it does not immerse them. Returning from this digression, permit me to ask: if, without trying to discover the type of student in question, we yet become aware, quite casually, that the type actually exists, is it not legitimate to infer that it is much more numerous than is commonly supposed? And if such students occasionally make their presence known even when we do not offer them the kind of instruction to render their wants articulate, is it not reasonable to infer that the provision of such instruction

would have the effect of revealing them in much greater numbers?

Indeed it does not seem unreasonable to suppose that a "strong substantial course" of the kind in question, in whatever great subject it were given, would be attended not only by considerable numbers of regular students but in a measure also by officers of instruction in other subjects and even perhaps by other qualified residents of an academic community. Only the other day one of my mathematical colleagues said to me that he would rejoice in an opportunity to attend such a course in physics. The dean of a great school of law not long ago expressed the wish that some one might write a book on mathematics in such a way as would enable students like himself to learn something of the innerness of this science, something of its spirit, its range, its ways, achievements and aspiration. I have known an eminent professor of economics to join a beginners' class in analytical geometry. Very recently one of the major prophets of philosophy declared it to be his intention to suspend for a season his own special activity in order to devote himself to acquiring some knowledge of modern mathematics. Similar instances abound and might be cited by any one not only at great length, but in connection with every cardinal division of knowledge. Their significance is plain. They are but additional tokens of the fact that the race of catholic-minded men has not been extinguished by the reigning specialism of the time, but that among students and scholars there are still to be found those whose curiosity and intellectual interests surpass all professional limits and crave instruction more generic in kind, more liberal, if you please, and ampler in its scope, than our vocationalized programs afford.

As to the question of values, I maintain

that the desire of such men is entirely legitimate, that it is wholesome and praiseworthy, that it deserves to be stimulated, and that universities ought to meet it, if they can. Indeed, all this seems to me so obvious that I find it a little difficult to treat it seriously as a question. If the matter must be debated, let it be debated on worthy ground. To say, as proponents sometimes say, that, inasmuch as all knowledge turns out sooner or later to be useful, students preparing for a given vocation by specializing in a given field may profitably seek some general acquaintance with other fields *because* such general knowledge will indirectly increase their vocational equipment, is to offer a consideration which, though in itself it is just enough, yet degrades the discussion from its appropriate level, which is that of an ideal humanity, down to the level of mere efficiency and practicalism. No doubt one engaged in minutely studying the topography of a given locality because he intends to reside in it might be plausibly advised to study also the general geography of the globe on the ground that his special topographical knowledge would be thus enhanced, and that, moreover, he might some time desire to travel. But if we ventured to counsel him so, he might reply: What you say is true. But why do you ply me with such low considerations? Why do you regard me as something crawling on its belly? Don't you know that I ought to acquire a general knowledge of geography, not primarily because it may be useful to me as a resident here or as a possible traveler, but because such knowledge is essential to me in my character as a man? The rebuke, if we were fortunately capable of feeling it, would be well deserved. A man building a bridge is greater than the engineer; a man planting seed is greater than the farmer; a man teaching calculus is greater than the

mathematician; a man presiding at a faculty meeting is greater than the dean or the president. We may as well remember that man is superior to any of his occupations. His supreme vocation is not law or medicine or theology or commerce or war or journalism or chemistry or physics or mathematics or literature or any specific science or art or activity; it is intelligence, and it is this supreme vocation of man as man that gives to universities their supreme obligation. It is unworthy of a university to conceive of man as if he were created to be the servant of utilities, trades, professions and careers; these things are for *him*: not ends but means. It is said that intelligence is good because it prospers us in our trades, industries and professions; it ought to be said that these things are good because and in so far as they prosper intelligence. Even if we do not conceive the office of intelligence to be that of contributing to being in its highest form, which consists in understanding, even if we conceive its function less nobly as that of enabling us to adjust ourselves to our environment, the same conclusion holds. For what is our environment? Is it wholly or mainly a matter of sensible circumstance—sea and land and sky, heat and cold, day and night, seasons, food, raiment, and the like? Far from it. It is rather a matter of spiritual circumstances—ideas, sentiments, doctrines, sciences, institutions, and arts. It is in respect of this ever-changing and ever-developing world of spiritual things, it is in respect of this invisible and intangible environment of life, that universities, whilst aiming to give mastery in this part or that, are at the same time under equal obligation to give to such as can receive it some general orientation in the whole.

And now as to the question of feasibility. Can the thing be done? So far as mathematics is concerned I am confident that

it can, and I have a strong lay suspicion that it can be done in all other subjects.

It is my main purpose to show, with some regard to concreteness and detail, that the thing is feasible in mathematics. Before doing so, however, I desire to view the matter a little further in its general aspect and in particular to deal with some of the considerations that tend to deter many scientific specialists from entering upon the enterprise.

One of the considerations, and one, too, that is often but little understood, and so leads to wrong imputations of motive, though it is in a sense distinctly creditable to those who are influenced by it, is the consideration that relates to intricacy and technicality of subject-matter and doctrine. Every specialist knows that the principal developments in his branch of science are too intricate, too technical and too remote from the threshold of the matter to be accessible to laymen, whatever their abilities and attainments in foreign fields. Not only does he know that there is thus but relatively little of his science which laymen can understand but he knows also that the portions which they can not understand are in general precisely those of greatest interest and beauty. And knowing this, he feels, sometimes very strongly, that were he to endeavor by means of a lecture course to give laymen a general acquaintance with his subject, he could not fail to incur the guilt of giving them, not merely an inadequate impression, but an essentially false impression, of the nature, significance and dignity of a great field of knowledge. His hesitance therefore, is not due, as it is sometimes thought to be, to indifference or to selfishness. Rather is it due to a sense of loyalty to truth, to a sense of veracity, to an unwillingness to mislead or deceive. Of course strange things do sometimes happen, and it is barely con-

ceivable that once in a long time nature may, in a sportive mood, produce a kind of specialist whose subject affects him much as the possession of an apple or a piece of candy affects the boy who goes round the corner in order to have it all himself. But if the type exist, not many men could claim the odd distinction of belonging to it. Specialists are as generous and humane as other men. Their subjects affect them as that same boy is affected when, if he chance to come suddenly upon some strange kind of flower or bird, he at once summons his sister or brother or father or mother or other friend to share in his surprise and joy. There is this difference, however—the specialist must, unfortunately, suffer *his* joy in solitude unless and until he finds a comrade in kind. I admit that the deterrent consideration in question is thoroughly intelligible. I contend that the motive it involves presents an attractive aspect. But I can not think it of sufficient weight to be decisive. It involves, I believe, an erroneous estimate of values, a fallacious view of the ways of truth to men. A few years ago, when making a railway journey through one of the most imposing parts of the Rocky Mountains, I was tempted like many another passenger to procure some photographs of the scenery in order to convey to far-away friends some notion of the wonders of it. So far, however, did the actual scenery surpass the pictures of it, excellent as these were, that I decided not to buy them, feeling it were better to convey no impression at all than to give one so inferior to my own. No doubt the decision might be defended on the ground of its motive. Did it not originate in a certain laudable sense of obligation to truth? Nevertheless, as I am now convinced, the decision was silly. For in accordance with the same principle it is plain that I ought to have wished to have my own impressions

erased, seeing that they must have been quite as inferior to those of a widely experienced mountaineer as those which the pictures could have given were inferior to mine. Who is so foolish as to argue that no one should learn anything about, say London, unless he means to master all its plans, its architecture and its history in their every phase, feature and detail? Who would contend that, because we are permitted to know only so little of what is happening in the European war, we ought to remain in total ignorance of it? Who would say that no one may with propriety seek to learn something about ancient Rome unless he is bent on becoming a Gibbon or a Mommsen? It is undoubtedly true that an endeavor to present a body of doctrine or a science to such as can not receive it fully must result in giving a false impression of the truth. But the notion that such an endeavor is therefore wrong is a notion which, if consistently and thoroughly carried out, would put the human mind entirely out of commission. All impressions, all views, all theories, all doctrines, all sciences are false in the sense of being partial, imperfect, incomplete. "Il n'y a plus des problèmes résolus et d'autres qui ne le sont pas, il y a seulement des problèmes *plus ou moins résolus*," said Henri Poincaré. Every one must see that, but for the helpfulness of views which because incomplete are also in a measure false, even the practical conduct of life, not to say the advancement of science, would be impossible. There is no other choice: either we must subsist upon fragments or perish.

Again, many a specialist shrinks from trying to present his subject to laymen because he looks upon such activity as a species of what is called popularization of science, and he believes that such popularization, even in its best sense, closely resembles vulgarization in its worst. He

fancies that there is a sharp line bounding off knowledge that is mere knowledge from knowledge that is scientific. In his view science is for specialists and for specialists only. He declines, on something like moral and esthetic grounds, to engage in what he calls playing to the gallery. It might, of course, be said that there is more than one way of playing to the gallery. It could be said that one way consists in acting the rôle of one who imagines that his intellectual interests are so austere and elevated and his thought so profound that a just sense of the awful dignity of his vocation imposes upon him, when in presence of the vulgar multitude, the solemn law of silence. It would be ungenerous, however, if not unfair, to insist upon the justice of such a possible retort. Rather let it be granted, for it is true, that much so-called popularization of science is vicious, relieving the ignorant of their modesty without relieving them of their ignorance, equipping them with the vocabulary of knowledge without its content and so fostering not only a vain and empty conceit, but a certain facility of speech that is seemly, impressive and valuable only when, as is too seldom the case, it is accompanied by solid attainments. To say this, however, is not to lay an indictment against that kind of scientific popularization which was so happily illustrated by the very greatest men of antiquity, which was not disdained even by Galileo in the beginnings of modern science nor by Leonardo da Vinci, and which in our own time has engaged the interest and skill of such men as Clifford and Helmholtz, Haeckel and Huxley, Mach, Ostwald, Enriques and Henri Poincaré. It is not to arraign that variety of popularization which any one may behold in the constant movement of ideas, once reserved exclusively for graduate students, down into undergraduate curricula and which has,

for example, made the doctrine of limits, analytical geometry, projective geometry, and the notions of the derivative and the integral available for presentation to college freshmen or even to high-school pupils. It is not to condemn that kind of popularization which is so natural a process that it actually goes on in a thousand ways all about us without our deliberate cooperation, without our intention or our consent, and has enriched the common sense and common knowledge of our time with countless precious elements from among the scientific and philosophic discoveries made by other generations of men.

Finally it remains to mention the important type of specialist in whom strongly predominates the predilection for research as distinguished from exposition. He knows, as every one knows, that through what is called practical applications of science many a scientific discovery is made to serve innumerable human beings who do not understand it and innumerable others who never can. He may or may not believe in avocational instruction; he may or may not regard intelligence as an ultimate good and an end in itself; he may or may not think that the arts and agencies for the dissemination of knowledge, as distinguished from the discovery and practical applications of truth, are important; he may or may not know that the art and the gifts of the great expositor are as important and as rare as those of the great investigator and less often owe their success to the favor of accident or chance. He may not even have seriously considered these things. He does know his own predilection; and so strong is his inclination towards research that for *him* to engage in exposition, especially in popular exposition, in avocational instruction for laymen, would be to sin against the authority of his vocation. This man, if he have intellectual powers fairly corresponding to the seeming author-

ity and urgency of his inner call, belongs to a class whose rights are peculiarly sacred and whose freedom must be guarded in the interest of all mankind. It is not contended that every representative of a given subject is under obligation to expound it for the avocational interest and enlightenment of laymen. The contention is that such exposition is so important a service that any university department should contain at least one man who is at once willing and qualified to render it.

I come now to the keeping of my promise. It is to be shown that the service is practicable in the subject of mathematics and how it is so. Let us get clearly in mind the kind of persons for whom the instruction is to be primarily designed. They are to be students of "maturity and power"; they do not intend to become teachers, much less producers, of mathematics; they are probably specializing in other fields; they do not aim at becoming mathematicians; their interest in mathematics is not vocational, it is avocational; it is the interest of those whose curiosity transcends the limits of any specific profession or any specific form or field of activity; each of them knows that, whatever his own field may be, it is penetrated, overarched, compassed about by an infinitely vaster world of human interests and human achievements; they feel its immense presence, the poignant challenge of it all; as specialists they will win mastery over a little part, but they have heard the call to intelligence and are seeking orientation in the whole; this they know is a thing of mind; they are aware that the essential environment of a scholar's life is a spiritual environment—the invisible and intangible world of ideas, doctrines, institutions, sciences and arts; they know or they suspect that one of the great components of that world is mathematics; and so, not as candidates for a profession or a degree, but in their higher

capacity as men and women, they desire to learn something of this science viewed as a human enterprise, as a body of human achievements; and they are willing to pay the price; they are not seeking entertainment, they are prepared to work—to listen, to read and to think.

And now we must ask: What measure of mathematical training is to be required of them as a preparation? In view of what has just been said it is evident that such training is not to be the whole of their equipment nor even the principal part of it, but it is an indispensable part. And the question is: How much mathematical knowledge and mathematical discipline is to be demanded? I have no desire to minimize my present task. I, therefore, propose that only so much mathematical preparation shall be demanded as can be gained in a year of collegiate study. Most of them will, of course, have had more; but I propose as a hypothesis that the amount named be regarded as an adequate minimum. But it does not include the differential and integral calculus. And is it not preposterous to talk of offering graduate instruction in mathematics to students who have not had a first course in the calculus? I am far from thinking so. A little reflection will suffice to show that in the case of such students as I have described it is very far from preposterous. In my opinion the absurdity would rather lie in demanding the calculus of them. No one is so foolish as to contend that a first course in the calculus is a *sufficient* preparation for undertaking the pursuit of graduate mathematical study. But to suppose it necessary is just as foolish as to suppose it sufficient. There was a time when it *was* necessary, and the belief that it is necessary now owes its persistence and currency to the inertia then acquired. Formerly it *was* necessary, because formerly all advanced courses, at

least all initial courses of the kind, were either prolongations of the calculus, like differential equations, for example, or else courses in which the calculus played an essential instrumental rôle as in rational mechanics, or the usual introductions to function theory or to higher geometry or algebra. But, as every mathematician knows, that time has passed. It is true that courses for which a preliminary training in the calculus is essential still constitute and will continue to constitute the major part of the graduate offer of any department of mathematics. And quite apart from that consideration, it seems wise, in the case of intending graduate students who purpose to specialize in mathematics, to enforce the usual calculus requirement as affording some slight protection against immaturity and the lack of seriousness. But every mathematician knows that it is now practicable to provide a large and diversified body of genuinely graduate mathematical instruction for which the calculus is strictly not prerequisite.

Fortunately it is just the material that is thus available which is in itself best suited for the avocational instruction we are contemplating. As the calculus is not to be presupposed it goes without saying that this subject must find a place in the scheme. For evidently an advanced mathematical course devised and conducted in the interest of general intelligence can not be silent respecting "the most powerful weapon of thought yet devised by the wit of man." Technique is not sought and can not be given. The subject is not to be presented as to undergraduates. For the most part these gain facility with but little comprehension. It is to be presented to mature and capable students who seek, not facility, but understanding. Their desire is to acquire a general conception of the nature of the calculus and of its place in science and

the history of thought—such a conception as will at least enable them as educated men to mention the subject without a feeling of sham or to hear it mentioned without a feeling of shame. A few well-considered lectures should suffice. At all events it would not require many to show the historical background of the calculus, to explain the nascence and nature of the scientific exigencies that gave it birth, to make clear the concepts of derivative and integral as the two central notions of its two great branches, and to present a few simple applications of these notions to intelligible problems of typical significance. Even the idea of a differential equation could be quickly reached, the nature of a solution explained, and simple examples given of physical and geometric interpretations. As to the range and power of the calculus, a sense and insight can be given, in some measure of course by a reference to its literature, but much more effectively by a few problems carefully selected from various fields of science and skillfully explained with a view to showing wherein the methods of the calculus are demanded and how they serve. Is not all this elementary and undergraduate? In point of nomenclature, yes. It is not necessary, however, to let words deceive us. We teach whole numbers to young children, but even Weierstrass was not aware of the logico-mathematical deeps that underlie cardinal arithmetic.

The calculus, however, is hardly the topic with which the course would naturally begin. A principal aim of the course should be to show what mathematics, in its inner nature, is—to lay bare its distinctive character. Its distinctive character, its structural nature, is that of a "hypothetico-deductive" system. Probably, therefore, it would be well to begin with an exposition of the nature and function of postulate systems and of the great rôle such systems

have always played in the science, especially in the illustrious period of Greek mathematics and even more consciously and elaborately in our own time. It is plain that such an exposition can be made to yield fundamental insight into many matters of interest and importance not only in mathematics, but in logic, in psychology, in philosophy, and in the methodology of natural science and general thought. The material is almost superabundant, so numerous are the postulate systems that have been devised as foundations for many different branches of geometry, algebra, analysis, *Mengenlehre* and logic. A general survey of these, were it desirable to pass them all in review, would not be sufficient. It will be necessary to select a few systems of typical importance for minute examination with reference to such capital points as convenience, simplicity, adequacy, independence, compatibility and categorialness. The necessity and presence of undefined terms in any and all systems will afford a suitable opportunity to deal with the highly important, much neglected and little understood subject of definition, its nature, varieties and function, in light of the recent literature, especially the suggestive handling of the matter by Enriques in his "Problems of Science." A given system once thus examined, the easy deduction of a few theorems will suffice to show the possibility and the process of erecting upon it a perfectly determinate and often imposing superstructure. And so will arise clearly the just conception of a mathematical doctrine as a body of thought composed of a few undefined together with many defined ideas and a few primitive or postulated propositions with many demonstrated ones, all concatenated and welded into a form independent of will and temporal vicissitudes. Revelation of the charm of the science will have been begun. A

new revelation will result when next the possibility is shown of so interchanging undefined with defined ideas and postulates with demonstrated propositions that, despite such interchange of basal with superstructural elements, the doctrine as an autonomous whole will remain absolutely unchanged. But this is not all nor nearly all. It is only the beginning of what may be made a veritable apocalypse. Of great interest to any intellectual man or woman, of very great interest to students of logic, psychology, or philosophy, should be the light which it will be possible in this connection to throw upon the economic rôle of logic and upon the constitution of mind or the world of thought. I refer especially to the recently discovered fact that in interpreting a system of postulates we are not restricted to a single possibility, but that, on the contrary, such a system admits in general of a literally endless variety of interpretations; which means, for such is the make-up of our *Gedankenwelt*, that an infinitude of doctrines, widely different in respect of their psychological character and interest, have nevertheless a common form, being isomorphic, as we say, logically one, though spiritually many, reposing on a single base. And how foolish the instructor would be not to avail himself of the opportunity of showing, too, in the same connection, how various mathematical doctrines that differ not only psychologically, but logically also, are yet such that, by virtue of a partial agreement in their bases, they intersect one another, owning part of their content jointly, whilst being, in respect of the rest, mutually exclusive and incompatible. If, for example, it be some Euclidean system that he has been expounding, he will be able readily to show upon how seemingly slight changes of base there arise now this or that variety of non-Euclidean geometry, now a projective or an inversion

geometry or some species or form of higher dimensionality. I need not say that analogous phenomena will in like manner present themselves in other mathematical fields. And it is of course obvious that as various doctrines are thus made to pass along in deliberate panorama it will be feasible to point out some of their salient and distinctive features, to indicate their historic settings, and to cite the more accessible portions of their respective literatures. Naturally in this connection and in the atmosphere of such a course the question will arise as to why it is that, or wherein, the hypothetico-deductive method fails of universal applicability. So there will be opportunity to teach the great lesson that this method is not rudimentary, but is an ideal, the ideal of intellect and science; to teach that mathematics is but the name of its occasional realization; and that, though the ideal is, relatively speaking, but seldom attained, yet its lure is universal, manifesting itself in the most widely differing domains, in the physical and mechanical assumptions of Newton, in the ethical postulates of Spinoza, in our federal constitution, even in the ten commandments, in every field where men have sought a body of principles to serve them as a basis of doctrine, conduct or achievement. And if it shall thus appear that mathematics is very high-placed as being, in respect of its method and its form, the ideal and the lure of thought in general, the fault must be imputed, not to the instructor, but to the nature of things.

In all this study of the postulational method the impression will be gained that the science of mathematics consists of a large and increasing number of more or less independent, somewhat closely related and often interpenetrating branches, constituting, not a jungle, but rather an immense, diversified, beautifully ordered for-

est; and that impression is just. At the same time another impression will be gained, namely, that the various branches rest, each of them, upon a foundation of its own. This impression will have to be corrected. It will have to be shown that the branch-foundations are not really fundamental in the science but are, literally and genuinely, component parts of the superstructure. It will have to be shown that mathematics as a whole, as a single unitary body of doctrine, rests upon a basis of primitive ideas and primitive propositions that lie far below the so-called branch-foundations and, in supporting the whole, support these as parts. The course will, therefore, turn to the task of acquainting its students with those strictly fundamental researches which we associate with such names as C. S. Peirce, Schroeder, Peano, Frege, Russell, Whitehead and others, and which have resulted in building underneath the traditional science a logico-mathematical sub-structure that is, philosophically, the most important of modern mathematical developments.

It must not be supposed, however, that the instruction must needs be, nor that it should preferably be, confined to questions of postulate and foundation, and I will devote the remainder of the time at my disposal to indicating briefly how, as it seems to me, a large or even a major part of the course may concern itself with matters more traditional and more concrete.

Any one can see that there is an abundance of available material. There is, for example, the history and significance of the great concept of function, a concept which mathematics has but slowly extracted and gradually refined from out the common content and experience of all minds and which on that account can be not only defined precisely and intelligibly to such laymen as are here concerned, but can also be clarified

in many of its forms by means of manifold examples drawn from elementary mathematics, from the elements of other sciences, and from the most familiar phenomena of the work-a-day world.

Another available topic is the nature and rôle of the sovereign notion of limit. This, too, as every mathematician knows, admits of countless illustration and application within the radius of mathematical knowledge here presupposed. In this connection the structure and importance of what Sylvester called "the Grand Continuum," which so many scientific and other folk talk about unintelligently, will offer itself for explanation. And if the class fortunately contain students of philosophic mind, they will be edified and a little astonished perhaps when they are led to see that the method and the concept of limits are but mathematicized forms of a process and notion familiar in all domains of spiritual activity and known as idealization. Not improbably some of the students will be sufficiently enterprising to trace the mentioned similitude in some of its manifestations in natural science, in psychology, in philosophy, in jurisprudence, in literature and in art.

I have not mentioned the modern doctrine variously known as *Mengenlehre*, *Mannigfaltigkeitslehre*, the theory of point-sets, assemblages, manifolds or aggregates: a live and growing doctrine in which expert and layman are about equally interested and which, like a subtle and illuminating ether, is more and more pervading mathematics in all its branches. For the avocational instruction of lay students of "maturity and power" how rich a body of material is here, with all its fascinating distinctions of discrete and continuous, finite and infinite, denumerable and non-denumerable, orderless, ordered, and well-ordered, and with its teeming host of near-

lying propositions, so interesting, so illuminating, often so amazing.

Finally, but far from exhausting the list, it remains to mention the great subjects of invariants and groups. Both of them admit of definition perfectly intelligible to disciplined laymen; both admit of endless elementary illustration, of having their mutual relations simply exemplified, of being shown in historic perspective, and of being strikingly connected, especially the notion of invariance, with the dominant enterprise of man: his ceaseless quest for the changeless amid the turmoil and transformation of the cosmic flux.

CASSIUS J. KEYSER

COLUMBIA UNIVERSITY

PRELIMINARY REPORT ON A SHALER
MEMORIAL STUDY OF CORAL REEFS

A LIBERAL grant from the Shaler Memorial Fund of Harvard University, supplemented by a generous subsidy from the British Association for the Advancement of Science with an invitation to attend its meeting in Australia last August as a foreign guest, enabled me to spend the greater part of the year 1914 in visiting a number of islands in the Pacific Ocean with the object of testing various theories that have been invented to account for coral reefs. Thirty-five islands, namely, Oahu in Hawaii, eighteen of the Fiji group, New Caledonia of which the entire coast line was traced, the three Loyalty islands, five of the New Hebrides, Rarotonga in the Cook group, and six of the Society islands, as well as a long stretch of the Queensland coast inside of the Great Barrier reef of northeastern Australia, were examined in greater or less detail. A brief statement of my results has been published in the *Proceedings of the National Academy of Sciences* for March, 1915. A full report will appear later, probably in the *Bulletin of the Museum of Comparative Zoology* at Harvard College. The general conclusions reached are here briefly summarized.

Any one of the eight or nine theories of

coral reefs will satisfactorily account for the visible features of sea-level reefs themselves, provided the postulated conditions and processes of the invisible past are accepted; hence a study of the visible features of the reefs alone can not lead to any valid conclusion. Some independent witnesses must be interrogated, in the hope of detecting the true theory. The only witnesses, apart from sections obtained by deep and expensive borings, available for sea-level reefs are the central islands within oceanic barrier reefs, or the mainland coast within a continental barrier reef. The testimony of these witnesses has been too largely neglected, apparently because most investigators of coral reefs have been zoologists, little trained in the physiography of shore lines. Elevated reefs afford additional testimony in their structure and in the relation of their mass to its foundation; but these witnesses also have been insufficiently considered, perhaps because most investigators of reefs have, as zoologists, been little trained in structural geology; hence it seemed desirable to give as much time as possible on the Pacific islands to questioning the independent witnesses above designated, rather than to the study of the reef themselves.

The testimony of the first group of witnesses—the central islands of barrier reefs—convinced me that Darwin's theory of subsidence is the only theory competent to explain not only the development of barrier reefs from fringing reefs, but also the shore-line features of the central (volcanic) islands within such reefs; for the embayment of the central islands testify emphatically to subsidence, as Dana long ago pointed out: thus my results in the study of this old problem of the Pacific agree with those of several other recent students, especially Andrews, Hedley and Taylor of Australia, and Marshall of New Zealand. Darwin's theory of subsidence also gives by far the most probable explanation of atolls; for it is unreasonable to suppose that a subsidence of the ocean bottom should occur only in regions where the central islands of barrier reefs are present to attest it, and not in neighboring regions where reefs of identical appearance,

but without a central island, are given another name.

The testimony of the second group of witnesses—massive elevated reefs such as occur on certain Fiji Islands—convinced me that Darwin's theory of subsidence gives the only satisfactory explanation of the origin of such reefs also; for their limestones rest unconformably on the normally eroded surface of a preexistent foundation. The erosion of the foundation surface shows that it stood above sea-level before the reef was deposited upon it; and the occurrence of the reef shows that the eroded foundation subsided to receive its marine cover. Only after this subsidence was the compound mass uplifted. The mere occurrence of elevated reefs above sea level does not for a moment prove that they were formed during the emergence of their foundation.

All the still-stand theories of barrier reefs—that is, all the theories which involve a fixed relation of the reef foundation to the sea level during the formation of the reef mass—are excluded by evidence of submergence found in the embayed shore lines of the central islands within barrier reefs. It may seem overbold thus at a stroke to set aside several well-known theories, accepted by experienced observers; and so indeed it would be if these observers had discussed the features of the embayed central islands and had explicitly shown that their embayments are not due to submergence, but to some other cause. It is, however, a regrettable fact that the observers who adopted one or another of the still-stand theories took, like Darwin himself, practically no account of the embayed central islands, essential as the testimony of these islands is in the solution of the coral-reef problem. Such neglect is all the more remarkable in view of the clear statement, long ago published by Dana, regarding the pertinence and the value of the testimony afforded by the central islands of barrier reefs.

The glacial-control theory of coral reefs, recently elaborated by Daly with special reference to the lagoons of atolls, will not hold for barrier reefs. This theory assumes that no subsidence of the reef foundations took place,

and explains the lagoon floors of atolls as platforms abraded across preglacial sea-level reef-masses by the lowered and chilled sea of the glacial period after the corals were killed; the preglacial reef-masses having been formed by upward or outward growth on their still-standing foundations. It then explains the encircling reefs which now surround the lagoons as having been built up while the sea was rising and warming in postglacial time. But if the broad lagoons of large atolls, 20 or 30 miles in diameter, were thus formed, the central islands within narrow-lagoon barrier reefs should be cliffed all around their shore line, and they are not. Furthermore, this theory explains the embayments of central islands within barrier reefs as occupying new-cut valleys that were eroded during the glacial period of lowered sea level; but if this were the case, the new-cut valleys should be prolonged upstream from the embayment heads as incisions in the floors of preglacial valleys, thus producing a "valley-in-valley" landscape; and this is not true in any one of the hundreds of embayments seen during the past year. Furthermore, many of the embayments are so wide that, if they were opened by slow subaerial processes, all the spur ends ought to have been well cliffed by the sea; yet, as above stated, they are not cliffed. Finally many of the embayments are too wide to have been eroded during the last glacial epoch, or even during all the glacial epochs of the entire glacial period, if the valleys of the formerly glaciated volcanoes of central France are taken as standards of the amount of erosion that could be accomplished in such masses during such intervals of time. The glacial-control theory thus proves incompetent to explain barrier reefs, and it is therefore held to be generally incompetent to explain atolls also; it may have more importance on the borders of the coral zone, where the corals would most likely have been killed during the glacial period: the Marquesas Islands promise interesting results in this connection. The glacial-control theory has its greatest importance in conjunction with Darwin's theory of subsidence, for submergence during subsidence may have been

almost neutralized by the lowering of the sea-level during the oncoming of a glacial epoch, and at such a time coral reefs would broaden and lagoons would become shallow; but with the passing of a glacial epoch the return of ice-sheet water to the ocean would accelerate the submergence due to subsidence, and at such a time coral reefs might be more or less completely drowned: thus the discontinuity of certain reefs on so-called "platforms" may be explained.

All the phenomena which testify to the formation of coral reefs on subsiding foundations can be equally well explained by the assumption of a rise of the ocean surface around or over fixed foundations: but a rise of the ocean surface in any coral-reef region demands a rise of the whole ocean surface; and if the coral-reef foundations are to stand still, a rise of the whole ocean surface can be explained only as the diminished result of a greater rise of the ocean floor in some non-coral-reef region. The conditions involved in this alternative for the simple theory of local subsidence are so extravagantly improbable that, as soon as they are explicitly defined, they must be rejected.

No absolute demonstration of the origin of coral reefs, or, for that matter, of any other geological structure, is possible: the most that can be hoped for is a highly probable conclusion. The conclusions announced above in favor of Darwin's theory are believed to have about the same order of probability as that usually accepted as "proof" in geological discussions.

A number of local conclusions may be briefly announced as follows:

The elevated reef along the south coast of Oahu, Hawaii, was formed during or after a sub-recent period of subsidence, for its limestones enter well-defined valleys that must have been eroded when the island stood higher than now, before the reef-limestones were deposited in them.

The Fiji group has suffered various movements of subsidence and elevation by which its many islands were affected in unlike ways. Elevation has taken place at different times in different islands, for some of the elevated reefs

are elaborately dissected, others are very little dissected, and still others remain at sea-level. The embayments due to the latest subsidence on the larger islands, Viti Levu and Vanua Levu, are now largely filled with delta plains. All the reefs, those now elevated as well as those at sea-level, appear to have been formed during periods of subsidence, the evidence afforded by the elevated reefs of Vanua Mbalavu, Mango and Thithia, being especially significant on this point. The medium-sized island of Taviuni has few visible reefs, because its flanks and shores are flooded by sheets of recent lava. The small island of Wakaya seems to be a tilted block of lava beds, not a dissected volcano.

The extensive barrier reef of New Caledonia has grown up during a recent subsidence by which that long and maturely dissected island has been much reduced in size and elaborately embayed; but unlike most encircled islands this one was strongly cliffed around its southeastern end and along much of its northeastern side before the recent subsidence took place.

The two southeastern members of the Loyalty group, Maré and Lifu, are former atolls, evenly uplifted about 300 feet: Maré shows a small hill of volcanic rock in the center of its limestone plateau or elevated lagoon floor. Uvea, the northwestern of the three Loyalty Islands, is a slightly tilted atoll; its eastern side shows an uplifted reef in crescentic form, 100 or more feet high at the middle of its crescent, and slowly descending to sea-level at its horns; the tilted lagoon floor slowly deepens westward and is enclosed by disconnected, upbuilt reef-islands.

The New Hebrides show signs of uplift in their elevated reefs, and of depression in their embayments. There is some evidence that certain uplifted fringing reefs on the island of Efaté, near the center of the group, were formed during pauses in a subsidence that preceded their uplift, and not during pauses in their uplift as inferred by Mawson. The narrowness of the lagoons enclosed by the barrier reefs that encircle certain strongly embayed islands in this group may be explained by supposing alternations of slow and rapid subsi-

dence, so that the earlier-formed reefs, which began to grow when the subsidence was slowly initiated, were drowned when it was later accelerated; and new reefs, thereupon begun on the shore line of that time would after a second period of slow subsidence stand near the present shore line, though the shore line is strongly embayed because the total subsidence has been large. The absence of reefs around the island of Ambrym is due to its abundant eruptions in recent time, the latest one being in December, 1913; scattered corals were seen growing on one of its sea-cliffed lava-streams, thus illustrating the initial stage of a fringing reef.

The Great Barrier reef of Australia, the largest reef in the world, with a length of some 1,200 miles and a lagoon from 15 to 70 or more miles wide, has grown upward during the recent subsidence by which the Queensland coast has, after a long period of still-stand, been elaborately embayed, as was pointed out by Andrews in 1902. A very recent uplift of ten feet has occurred, as was long ago noted by Jukes. There is reason for believing that a broadened reef-plain, with extensive land-fed deltas along the continental margin, had been formed before the recent subsidence took place; and it is this broadened reef, now submerged, that is thought to form the "platform" on which the Great Barrier reef has grown up. Guppy's suggestion that the platform or "submarine ledge" is due to marine abrasion before coral reefs were established here and that no subsidence has taken place can not be accepted. It is highly probable that the well-attested recent subsidence was due to a gentle flexure, by which the off-shore sea-bottom was bent down; and if so, the coastal submergence will give much too small a measure of the thickness of the distant barrier reef. In this respect the Great Barrier reef along the shore of a continent differs significantly from smaller barrier reefs around oceanic islands, in which the subsidence of the island and its reef are essentially uniform.

A few hours on shore at Raretonga, the southernmost member of the Cook group, sufficed to show that extensive embayments

formerly entering its elaborately carved mass are now occupied by delta plains and perhaps in part by slightly elevated reef- and lagoon-limestone.

Five islands of the Society group exhibit signs of recent subsidence in their intricately embayed shore lines, as has lately been announced by Marshall. A sixth, the cliff-rimmed island of Tahiti, the largest and youngest of the group, has suffered moderate subsidence after its cliffs were cut, but the resulting bays are now nearly all filled with delta plains which often advance into the narrow lagoon; hence a pause or still-stand has followed the latest subsidence. All the barrier reefs of this group appear to have been formed during the recent subsidence that embayed their central islands.

W. M. DAVIS

HARVARD UNIVERSITY

SCIENTIFIC NOTES AND NEWS

DR. RICHARD P. STRONG, professor of tropical diseases at the Harvard Medical School, has been appointed leader of the American Red Cross Sanitary Commission, which will assemble in Salonica about the middle of next month and proceed to the districts of Serbia and Austro-Hungary which are stricken with epidemics of typhus, cholera and other contagious diseases. The commission will be supported by the Red Cross and the Rockefeller Foundation. Dr. Strong has already sailed for Greece, and the rest of the expedition will sail by the end of this month. It includes Dr. Thomas W. Jackson, of Philadelphia; Dr. Hans Zinsser, professor of bacteriology, Columbia University; Dr. Andrew W. Sellards, Dr. George C. Shattuck and Dr. Francis B. Grinnell, of the Harvard Medical School. Dr. Nicolle, the French expert on typhus, has been invited to cooperate with the commission. Mr. Charles S. Eby, of Washington, lately connected with the United States Immigration service, is disbursing officer and secretary for the commission.

THE Rockefeller Foundation has made comprehensive plans for improving medical and hospital conditions in China. These are based

on the report of the special commission sent by the foundation to China. To carry out this work the foundation has established a special organization to be called the China Medical Board of the Rockefeller Foundation, constituted as follows: John D. Rockefeller, Jr., chairman; Wallace Buttrick, director; Harry Pratt Judson, Frank J. Goodnow, Dr. Simon Flexner, Jerome D. Greene, John R. Mott, Dr. William H. Welch, Wickliffe Rose, Starr J. Murphy, Dr. Francis W. Peabody and Frederick T. Gates. E. C. Sage is secretary of the board, and Roger S. Greene is to be the resident director in Pekin. The plan outlined by the commission looks to the development of medical education in China as the first step. With a view to building up a body of Chinese medical men able to teach medical science, the foundation has decided to establish six fellowships, each of \$1,000 gold a year and traveling expenses, to enable Chinese graduates to study abroad. Six fellows have been appointed, one of whom is already in this country.

The fifth annual award of the Willard Gibbs Medal, founded by William A. Converse, of Chicago, has been made to Arthur A. Noyes, director of the research laboratory of physical chemistry, Massachusetts Institute of Technology. Dr. Noyes in receiving the medal will address the Chicago Section of the American Chemical Society upon the evening of April 16, his medal address being "A System of Qualitative Analysis including nearly all the Metallic Elements." The recipient of this medal is determined by a jury of twelve, six of whom only can be members of the Chicago section, those outside the section being Alexander Smith, W. A. Noyes, W. H. Walker, T. W. Richards, Leo Baekeland and W. F. Hillebrand. Previous awards of this medal have been to Arrhenius, T. W. Richards, Baekeland and Remsen.

PROFESSOR ROBERT HALLOWELL RICHARDS was given a complimentary dinner on March 18 by the Mining and Metallurgical Society of America, the feature of which was the presentation of the gold medal of the society by the president, William R. Ingalls, former student under Professor Richards at the Massachusetts

Institute of Technology. The banquet was in the Chemists' Club, New York, with a distinguished gathering of representative metallurgists from various parts of the country. The speakers besides Mr. Ingalls and Professor Richards were: W. L. Saunders, president of the American Institute of Mining Engineers; Charles W. Goodale, general manager of the Boston and Montana Department of the Anaconda Copper Mine; F. A. Lidbury, president of the American Electro-Chemical Society, and David H. Browne, metallurgical expert of the International Nickel Company.

DR. J. WILLIAM WHITE, professor emeritus of surgery and one of the trustees of the University of Pennsylvania, expects to enter the American Ambulance Service in Paris during the coming summer, taking with him a number of surgeons, physicians and nurses from the University of Pennsylvania staff.

The following have been selected by the council of the Royal Society to be recommended for election into the society: Professor Frederick William Andrewes, Professor Arthur William Conway, Mr. Leonard Doncaster, Mr. John Evershed, Dr. Walter Morley Fletcher, Professor Arthur George Green, Mr. Henry Hubert Hayden, Dr. James Mackenzie, Professor John Cunningham McLennan, Dr. Arthur Thomas Masterman, Professor Gilbert Thomas Morgan, Dr. Charles Samuel Myers, Mr. George Clarke Simpson, Mr. Alan A. Campbell Swinton, and Mr. Arthur George Tansley.

To Surgeon-General William C. Gorgas has been awarded the Louis Livingston Seaman medal for progress and achievement in the promotion of hygiene and the mitigation of occupational disease.

At the thirty-third annual dinner of the faculty of medicine of McGill University held in Montreal on February 18, Dr. Lewellys Franklin Barker, of the Johns Hopkins University, was the guest of honor.

PROFESSOR GEORGE PEGRAM, of the department of physics of Columbia University, has been elected president of the Columbia chapter of the Sigma Xi.

DR. CHARLES H. T. TOWNSEND has been elected the first honorary member in the New York chapter of the Alpha Mu Pi Omega Medical Fraternity.

PROFESSOR A. LOOSS, formerly connected with the school of medicine, Cairo, Egypt, has retired from that position. His present address is Stephanstrasse 18, Leipzig, Germany.

DR. J. C. BOSE, who has been lecturing in the United States on physiological botany, sailed from San Francisco for the Orient on March 20.

DR. W. J. HUSSEY, professor of astronomy at the University of Michigan and director of the observatory, has returned to Ann Arbor, after having spent the past six months at La Plata University in South America.

News has been received from the University of Pennsylvania's Amazon expedition through its director, Dr. W. C. Farrabee. It is the first news that has come through in four months. Dr. Farrabee reports that he has spent three months at work in the interior, where he has been successful in getting much information and many specimens. He further states that he has just started for the highlands on the borders of Bolivia, Peru and Brazil, from which he had to turn back last August.

PROFESSOR WILLIAM TRELEASE, of the department of botany of the University of Illinois, has been granted leave of absence from the university until May 1, for a botanical expedition to Guatemala, Central America.

DR. JULIUS STIEGLITZ, professor of chemistry and director of analytical chemistry in the University of Chicago, has accepted an invitation to give courses in chemistry at the University of California during the summer term that begins June 21 and closes on August 1. Professor Stieglitz will give a seminar on special topics in organic chemistry and also a college course in organic chemistry.

ON March 3, Professor E. E. Barnard, director of the Yerkes Observatory, lectured before the California chapter of the Sigma Xi upon the subject: "Some of the Visible Results of Astronomical Photography." The

lecture was illustrated by a remarkable series of astronomical photographs.

DR. LELAND O. HOWARD delivered a lecture on "Insects and Disease" before the biological club and students of the medical department of Georgetown University, Washington, D. C., on March 11.

DR. L. A. BAUER gave an illustrated lecture, on March 15, at Smith College, Northampton, under the auspices of the Physics Club, entitled "Following the Compass."

PROFESSOR DAYTON C. MILLER, of the Case School of Applied Science, lectured, on March 4 and 5, at the State University of Iowa. His subjects were (1) "The Science of Musical Sounds" and (2) "The Physical Characteristics of Vowels." Professor Miller also addressed the seminar of the department of physics on some of the more technical parts of his investigations. Professor C. G. Derick, of the University of Illinois, delivered two lectures at the university on March 13. The first was on the subject "The Teacher in Research." The second was upon the study of valence through ionization and dealt largely with Professor Derick's own work.

DR. OTIS W. CALDWELL, professor in the University of Chicago, recently spent several days at the Kansas State Agricultural College, where he delivered several lectures to the students and scientific organizations of the college.

DR. FREDERICK WINSLOW TAYLOR, of Philadelphia, past president of the Society of Mechanical Engineers, known for his inauguration of methods of "scientific management," died on March 21 at the age of sixty-nine years.

It is announced that Dr. Philip Beck, head of the Austrian Army Medical staff, recently died of typhus fever.

DR. F. A. BATHER, of the British Museum, writing in the *Museum Journal* of February, 1915, states that some international scientific activities continue between the countries now at war. Thus the German collaborators of the International Catalogue of Scientific Literature continue to send their manuscript to the

central office in London, while the members of the International Commission on Zoological Nomenclature still record their votes without distinction of country. The British government also permits a limited import of scientific books from Germany and Austria.

A CABLEGRAM to the daily papers was quoted in the issue of SCIENCE of December 25, to the effect that the trained horses of Elberfeld had been requisitioned for an artillery battery and that they had been killed on the battlefield in Flanders. Fortunately this report has proved to be untrue. According to the *Frankfurter Zeitung* of January 22, Herr Krall, the owner of the horses, has written to that paper to the effect that they are safe and well in the hands of a competent horseman, although the experiments upon them are in abeyance during the war.

SIR CHARLES A. PARSONS, the distinguished engineer, has given £5,000 to the Royal Institution, London, for the general purposes of the institution.

THE thirty-seventh annual meeting of the American Library Association will be held at Berkeley, Calif., on June 30.

THE eighth annual meeting of the American School Hygiene Association will take place in the city of San Francisco, June 25-26, 1915. Arrangements for this meeting are being made through the organization committee of which Professor Lewis M. Terman, Stanford University, Stanford, Calif., is chairman. Professor Terman is also chairman of the program committee. The influence of the American School Hygiene Association was very largely responsible for the great success of the Fourth International Congress on School Hygiene which was held in the city of Buffalo in the summer of 1913. It is hoped that the general interest stimulated by this International Congress may be productive of a large and an effective meeting in San Francisco.

UNIVERSITY AND EDUCATIONAL NEWS

WE have received the following telegram signed by five professors of the University of Utah:

"Fourteen members of the University of Utah faculty have resigned—Cummings, dean of art and science; Holman, dean of law school; six department heads—Roylance, history; Ebaugh, chemistry; Vorhies, biology; Mattill, physiology and physiological chemistry; Peterson, psychology, and six others—Butler and Blood, English; Sharp, histology; Hedger, registrar; Stephens, law; Thiel, German. Of the eleven members of the American Association for the Advancement of Science in the University of Utah, but three remain. The immediate cause is the recent dismissal of Knowlton, in physics, Wise, in German, and Bing and Snow, in English, and the demotion of Professor Marshall, for twenty-three years head of the English department and Reynolds, professor of English. For specious and fluctuating reason, without heed to petition from students, faculty, alumni and others, the president refuses an investigation and has been upheld by the board of regents. This is the culmination of a policy of repression that has been growing steadily in the past two or three years, resulting in an entire lack of mutual confidence. We believe this should be known at once for the safeguarding of our successors in the profession. They should come only with their eyes open."

THE dedication of the new Julius Rosenwald Hall in connection with the ninety-fourth convocation of the University of Chicago was held on the morning of March 16. The program included addresses by President Harry Pratt Judson, Professor Rollin D. Salisbury, head of the department of geography and dean of the Ogden Graduate School of Science; Professor Thomas Chrowder Chamberlin, head of the department of geology, and seven alumni of the university who took their degrees in the departments which will use the new building: Eliot Blackwelder, A.B., '01, Ph.D., '14, professor of geology, the University of Wisconsin; Frank Walbridge De Wolf, S.B., '03, director of the State Geological Survey of Illinois; William Harvey Emmons, Ph.D., 1904, professor of mineralogy and geology, the University of Minnesota, director of

the Geological Survey of Minnesota; Wallace Walter Atwood, S.B., '97, Ph.D., 1903, professor of physiography, Harvard University; Edwin Bayer Branson, Ph.D., 1905, professor of geology, the University of Missouri; Ermine Cowles Case, Ph.D., 1898, professor of historical geology and paleontology, the University of Michigan; George Frederick Kay, Ph.D., '14, professor of economic geology and petrology of the State University of Iowa, director of the Geological Survey of Iowa. The exercises were held in the lecture room of the new hall, and the entire building, with its equipment, was then placed on exhibition.

A new site for the Fuertes Observatory of Cornell University has been approved by the committee on buildings and grounds, on the recommendation of a subcommittee which had considered the matter in consultation with Dean Haskell of the College of Civil Engineering. The observatory was torn down last fall to make room for the new drill hall. It is to be erected on the summit of a knoll just north of Beebe Lake, near the east end of the lake. The site is on a part of the Kline farm which was purchased by the university a year or two ago. It is just 900 feet above sea level.

At a meeting of the Yale corporation on March 15, Dr. John Zeleny, professor of physics at the University of Minnesota, was appointed professor in the Sheffield School to succeed Professor Charles S. Hastings. Dr. J. M. Slemons, professor of obstetrics and gynecology in the University of California, was appointed to the corresponding chair in the medical school. Dr. Hiram Bingham was promoted to be professor of Latin-American history; Dr. T. S. Taylor, now instructor, was made assistant professor of physics in the college; Dr. A. F. Holding, of the Cornell Medical School, was made assistant professor of radiography in the medical school; Dr. A. M. Bateman, of Queen's College, was made instructor in biology, and Mr. H. L. Bruce, of the University of California, instructor in engineering.

Dr. HERBERT M. EVANS, associate professor of anatomy in the Johns Hopkins University

and research associate in the department of embryology of the Carnegie Institution of Washington, has accepted a call to the professorship in anatomy and directorship of the department of anatomy of the University of California. Dr. Evans will assume his new duties on July first.

Dr. W. V. BINGHAM, assistant professor of psychology and education at Dartmouth College and for the past three years director of the summer session, has accepted appointment as professor of psychology in the Carnegie Institute of Technology at Pittsburgh. Dr. Bingham will not leave Hanover until September, after the summer session.

AMONG new promotions at the University of Chicago are the following: To a professorship: Henry Chandler Cowles, of the department of botany, Charles Joseph Chamberlain, of the department of botany; Otis William Caldwell, of the college of education (botany). To an assistant professorship: J. Harlen Bretz, of the department of geology; George William Bartelmez, of the department of anatomy; Elbert Clark, of the department of anatomy. To an instructorship: Harold S. Adams, of the department of physiology.

Dr. CHARLES KENNETH TINKLER has been appointed to the readership in chemistry tenable in the home science department of King's College for Women, London. He has been a research student of the University of Edinburgh, and since 1904 lecturer and demonstrator in chemistry in the University of Birmingham.

DISCUSSION AND CORRESPONDENCE

CONRAD RÖNTGEN

THE twenty-seventh of March marks the seventieth birthday of Conrad Röntgen, an event which was to have been jointly commemorated by physicists of all nationalities, especially English, French and German, the three which have contributed most markedly to the development of the new era in physics—an era which may with some reason be dated from the announcement in January, 1896, of the discovery of X-rays.

But when last summer the spirit of this new world which has been created by modern science, the spirit of reason, of cooperation, or internationalism, was submerged in the wave of blind nationalism which swept the world back a thousand years towards barbarism, when the crowning glory of science, the objective, impartial search for truth was forgotten, and prejudice and hate alone dictated the words and acts of men, then it was felt necessary to abandon the plans for the Röntgen celebration.

But here in America where, let us hope, the spirit and the method of science still find some advocates, it is fitting that on the twenty-seventh of March we bring honor and appreciation to the seventy-year-old author of one of the world's greatest discoveries—Conrad Röntgen.

UNIVERSITY OF CHICAGO,
March 18, 1915

THE CONTENTS OF A SHARK'S STOMACH

TO THE EDITOR OF SCIENCE: I have received from Mr. W. F. Cameron, of Zamboanga, P. I., a Stanford engineer, a photograph of a rare shark, *Rhinodon typicus*, a specimen about twenty feet long, taken on the island of Cebu. A notable feature about this shark, which has a very big mouth and small teeth, is that it had in its stomach 7 leggings, 47 buttons, 3 leather belts and 9 shoes. He had probably captured the cast-off garments of some company, otherwise the question arises—What became of the odd legging and the odd shoe?

DAVID STARR JORDAN

LELAND STANFORD JUNIOR UNIVERSITY

THE SCALED AMPHIBIA OF THE COAL MEASURES

THE preservation of scales among true Amphibia has been well known for many years, and their presence has been commented on by Huxley, Cope, Dawson and others. Recently the question of the crossopterygian ancestry of the Amphibia has received considerable support through the researches of Gregory, Watson, Broom and Williston, so that it will be of interest to state here the conditions of

the scales among the few species of Amphibia from the Coal Measures which show these structures. Scales are known on several genera of diverse relationship and seem to have been present independent of any common ancestry. These structures, presently to be described, are true scales, and are not to be confused with osseous scutes and ventral scutellæ. These latter structures will be dealt with more fully in another place.

Small scales hexagonal in form have been observed in a branchiosaurian genus, *Micrerpeton*, from North America, though this discovery has not so far been confirmed on additional material, although known to occur in another genus, *Eumicrerpeton*. From the Coal Measures of Ohio come two scaled microsaurian genera, one of which is *Cercariomorphus*, described by Cope, though never figured. The scales in this genus do not show many of the fish characteristics, though they resemble remotely some of the more aberrant forms. The scales are dermal tubercles inserted in the skin, without any definite plan of imbrication, such as is common among the fishes, although the scales have a definite arrangement simulating the fishes. The pattern shows a remote resemblance to some of the early ganoids. They are, moreover, true scales, and as such possibly indicate one more link added to the already full chain of facts which ally the Amphibia and the fishes.

The other genus from Ohio possessing scales is imperfectly known, but was tentatively allied, some years ago, to the genus *Ichthyerpeton*, described many years ago by Huxley from the Coal Measures of Ireland. There is no assurance that the forms are so closely related. They both possess scales of a similar pattern and have an identical form of vertebra. The scales in the only known American species are so badly scattered that nothing can be said of their arrangement. Dawson's work on the scaled Amphibia of the Coal Measures of Nova Scotia is well known. He has figured and described very completely the scales of *Hylonomus*. They bear a great resemblance to the scales of *Cercariomorphus*.

The question now before us is whether the

scales of these few species of Coal Measures Amphibia are sufficiently fish-like to be of service in the derivation of the Amphibia from the fishes. One would think that they might be, and it is the intention of the writer to describe and illustrate these structures fully; clearly distinguishing between scales, osseous scutes and ventral scutellæ. These latter may be scale-like, but are always confined to the myomeres of the abdomen, thorax and throat. That some of the ventral scutellæ have a scale-like arrangement is certain, but this arrangement can be accounted for on other grounds. The writer is confident that the ventral scutellæ have an entirely different origin, ontogenetically and phylogenetically, from true scales.

THE COTTON WORM MOTH IN 1912

AN enormous migratory flight of the cotton worm moth, *Alabama argillacea* Hubn., was recently reported by Dr. A. P. Saunders¹ as occurring at Clinton, N. Y., on October 10, 1912, the moths swarming into town about 3 A.M. He states also that two or three days earlier a large invasion of the moths occurred at London, Ontario.

It is therefore of especial interest to note that another huge swarm, probably of the same wave of migration, appeared at Hanover, N. H., two days later than at Clinton, N. Y., viz., the early morning of October 12, 1912. Wind-dows and doors of business houses that had been brightly illuminated during the night were literally covered in the morning with these handsome brown moths.

The facts, so far as they go, seem to warrant the conclusion, or at least the hypothesis, that a great wave of these insects from the cotton growing Gulf States was moving in a northeasterly direction at the rate of about 80-100 miles per night. This would require an average rate of flight of only 8-10 miles per hour. Continuing on the same course at the same rate the wave would have reached Augusta,

and perhaps Bangor, Me., on October 14, though it is quite possible that the rather heavy rain that fell in New Hampshire on the night of the 12th and 13th may have delayed the flight or changed the direction of its course. Records from that region will be awaited with much interest. Clinton, N. Y., is roughly 300 miles due east of London, Ont., lat. 43° N. Hanover, N. H., is about 160 miles northeast of Clinton, and 43° 42' N. The part of the wave front that passed through London, Ont., presumably passed considerably to the north of Clinton, if the moths were guided at all by the prevailing winds of October 9 in that vicinity, and traveled, as would be expected, in a northeasterly direction over the length of Lake Ontario.

In a case of this kind, in which winged creatures wander far from their native habitat, it is natural to suppose that the wind has played a prominent part in the dispersal, as when an occasional murre is driven inland by the storms of winter. So far as I have been able to learn, however, from a somewhat superficial examination of the records of the weather conditions of the time, I have found no evidence of any notable atmospheric disturbance sufficient to account for this apparently large and extensive migration. In Ontario and the northeastern states the moths would seem to have encountered only moderate southwest winds, followed on the 10th-12th by unsettled weather and variable winds of no great velocity.

It is impossible at present to say whether light, which has such a powerful control over the movements of butterflies and, to a more limited extent, of moths, was or was not an important factor in this case, but it is a matter worth considering.

This migratory wave seems to have passed to the north of Massachusetts, if one may judge from the scanty data at hand, though Professor Fernald² has reported that earlier in the season (Sept. 21-25, 1912) a few of these moths were taken in that state. He mentions a large invasion in 1911, during the last week in September, and another on October 17, 1914,

¹ SCIENCE, January 8, 1915.

² SCIENCE, November 27, 1914.

around Worcester, Mass., and, about the same time, in Pittsfield.

These sporadic and easily traceable migrations of the cotton worm moth, in the opinion of the writer, afford a rare opportunity, with the cooperation of many observers, for a thorough investigation into the causes of insect dispersal. Such an investigation would be likely to bring to light some important facts, of common interest to students of evolution and of economic entomology.

DARTMOUTH COLLEGE,
HANOVER, N. H.

SCIENTIFIC BOOKS

Sugar Analysis: For Cane-sugar and Beet-sugar Houses, Refineries and Experiment Stations and as a Handbook of Instruction in Schools of Chemical Technology. By FERDINAND G. WIECHMANN, Ph.D. New York, Jno. Wiley & Sons. Third edition. 8vo. Pp. xiii + 307. 7 figs. Cloth, \$3.00.

The author "has endeavored to cast his material in a form in which it would prove most readily available in the several branches of the sugar industry," and has reduced repetition to a minimum. "The methods and means used in the analysis of sugar and in the analysis of materials used in sugar production, have first been fully discussed, and then specific analytical control of cane-sugar manufacture, of beet-sugar manufacture, and of refining, has been taken up for detailed consideration."

The first seven chapters are devoted to Properties of Sucrose; Instruments Used in Sugar Laboratories; Polariscopes and Accessories; Sucrose Determination by Optical Analysis; Sucrose Determination by Chemical Analysis; Sucrose Determination by Optical and Chemical Analysis; and, Constituents of Sugar Other Than Sucrose; the eighth chapter to Materials Used in the Sugar Industry, the ninth, tenth and eleventh chapters, respectively, to Analytical Control in Cane-sugar Manufacture; Analytical Control in Beet-sugar Manufacture; and, Analytical Control in Refineries. In the twelfth chapter, a *Résumé* of the Work of the International

Commission for Uniform Methods of Sugar Analysis is given. Twenty well-selected sugar tables and the index to the volume occupy the last 70 pages.

The portions dealing with the properties of sucrose, instruments, polariscopes and accessories, sucrose determination by optical methods, by chemical methods, by optical and chemical methods, and the constituents of sugar other than sucrose, are clear in definition without being overburdened with detailed description to be found in references cited. In some instances, however, more detailed directions would add value to the volume when being used for instructional purposes. For example, on page 123, in the direction for the determination of woody fiber, no precaution, such as covering the beaker with washed muslin, etc., is directed to prevent loss of portions of fiber in decanting, other than: "The water . . . is decanted carefully, in order to avoid any loss of the weighed sample."

On pages 71 and 178-179, in giving the method of Clerget, the author states that the use of subacetate of lead as a clarifying agent is not permissible, recommending, on page 71, specially prepared blood-carbon, and on pages 178-179 specially prepared bone-black, "if a decolorant must be used."

Some of the methods given in chapter 8, for the analysis of materials used in the sugar industry, could be substituted by more modern and expedient ones. That given on page 146, for the determination of calcium sulphide, could be substituted by the more expedient evolution method used in the steel and iron industry. On page 151, seventh line from the top, in the method for the determination of total phosphoric acid in phosphate paste, the direction, after making alkaline with ammonia and clearing with nitric acid, is: "Add about 10 grams of ammonium nitrate." This is neither necessary nor advisable, when the method of solution is that recommended at the top of the same page, viz., by nitric and hydrochloric acids. The rest of the method, as outlined on this page, could be substituted by that of the Association of Official Agricultural Chemists as given in Bulletin 107, Bureau of Chemistry. On page 153,

"the latent heat of steam formation" is given as 967, instead of 970.4. On page 154, the method given for the determination of moisture and volatile carbon in coal could be replaced by standard ones. On page 155, the author states that, from the data of the proximate analysis, "the calorific power of the coal can be *approximately* calculated by Lenoire's formula" which he gives. A description and instruction in the use of a standard calorimeter at this point would not be amiss. On page 158, under "Water," the direction is to dry total solids and the residue, before driving off organic and volatile matter, at 130 degrees Centigrade to constant weight, instead of at 103 degrees for one half hour. On page 162, the soap method for hardness is given, but no mention is made of the titration methods.

In the chapters on analytical control in cane-sugar factories, beet-sugar factories and refineries, the author tabulates the work involving control of sugar materials and products, indicating what determinations are necessary on each. He avoids repetition as much as possible by referring to the directions for analytical methods given in the chapters devoted to outlines and discussions. One would call attention to the direction for determination of sucrose in molasses, on page 181. Under Clerget, on this page the following is given: "The direct polarization and the polarization after inversion should be carried out on portions of one and the same solution; for this reason two or three times the normal weight of molasses should be dissolved in 500 c.c. of water. The determination is then carried out as previously directed." Doubtless he intends that the dilution should be to 500 c.c. instead of "dissolved in." Since in giving the method of Clerget on pages 71 and 178-179, it is stated that the use of subacetate of lead is not permissible, but if a decolorant must be used specially prepared blood-carbon or bone-black should be employed, the operator or student would refer to these directions when preparing his solution for the double polarization of molasses, thereby omitting clarification with lead compounds and subsequent deleading but resorting to decolorization with bone-

black or blood-carbon, unless he perchance referred to the Meissel-Hertzfeld method as given in chapter 6, page 94, which he is hardly expected to do since this method is given and discussed in the chapter given to the determination of sucrose by optical and chemical methods and not to the determination by optical methods as Clerget calls for. Evidently the author would not recommend clarification of molasses with subacetate of lead when determining sucrose by the Clerget method.

Chapter 12 is an invaluable addition to the volume, as a résumé of the work of the International Commission is here given, which is not always at the hands of the chemist, either in the original transactions or in compilation. It is commendable that this so-important work is compiled and condensed in an available form.

The tables given are well selected and will meet the needs of the sugar analyst, except table 18 (that used in calculating the percentage of commercial sugar recovered from the sucrose in the massecuite as given by I. H. Morse), which is incomplete and would be of little service except in refineries.

The subject-matter of the volume is well correlated, repetitions are few, and the style and appearance of the book are good. Although criticism is here brought of some of the methods of analysis, as given in chapter 8, and attention called to the method for the preparation of the solutions in the determination of sucrose in molasses, and to the incompleteness of table 18, this work will be an addition to any technical library and of aid to the analyst experimenter and student, when working on commercial sugars and allied products and following routine analytical work in sugar houses and refineries.

C. S. WILLIAMSON, JR.

TULANE UNIVERSITY OF LOUISIANA

Electric Arc Phenomena. By EWALD RASCH. Translated from the German by K. TORNBERG. New York, D. Van Nostrand Company. 1913. Pp. 194.

The introduction contains a discussion of the relative merits of the electromagnetic and

the electrodynamic theory of light in which the author demonstrates the ascendancy of Wilhelm Weber over James Clerk Maxwell and predicts that "the explanations furnished by the electronic theory . . . contain the germs of future progress in electric-light engineering." The reasons for this prophecy, however, are not disclosed.

After explaining what an arc is, the conditions under which it is formed and the method of adjustment the author describes the physical and chemical properties of typical electrode materials and the process of manufacture of carbon electrodes. This is followed by a brief discussion of the theory of electrical discharges based upon the electronic theory. In the fifth chapter the author reviews some of the investigations made upon spark discharges between electrodes of different shapes in air. The treatment of this subject seems scant and antiquated in view of the many pertinent investigations made during the past ten years. The effect of gas pressure, humidity, temperature and kind of gas is not considered.

The most valuable contributions to the subject are made in the last three chapters. The sixth chapter has to do with the voltage and current conditions in the direct and alternating-current carbon arc lamp, the seventh with the distribution of energy in carbon arc lamps and vapor tubes, and the eighth with the relation between power and light emitted by plain and mineralized carbon arc lamps and vapor tubes.

The author confesses that some of his remarks are of purely didactic nature, and these digressions, although prohibitive of smooth development of the subject, contain many valuable suggestions. In expressing his disapproval of the term "watts per candle" the author has anticipated the recent suggestion of the term "lumens per watt." In remarking that "physiological effects can no more be expressed in mechanical horse-power than can, for instance, Beethoven's 'Ninth Symphony'" it would seem, in view of the measurements reported by our modern nutrition laboratories, that the author might have chosen a less vulnerable example. The text at times seems to rise above the subject, the discussion

in places being supported by cosmogonic reflections and the fourth dimension.

MASSACHUSETTS INSTITUTE OF TECHNOLOGY

SPECIAL ARTICLES

LIGHT AND THE RATE OF GROWTH IN PLANTS

A STUDY of the development of about a hundred seed-plants in darkness in an equable temperature chamber from 1900-03 in the New York Botanical Garden gave foundation for the following statement:

The failure of a large proportion of the forms examined to make an accelerated or exaggerated growth when freed from the influence of light, even when provided with an adequate food-supply, shows that light has no invariable or universal relation to increase in length, or thickness or to the multiplication or increase in volume of separate cells.¹

Precision appliances for the measurement of illumination and of other environmental conditions in daylight were not available at that time, and it was therefore not possible to follow the contrasting reactions which accompanied illumination and shading of the large plants which were the subjects in the extended experiments. In one series, however, the peduncles and scapes of *Arisaema* nearing the end of their period of elongation showed in initial acceleration when light was totally excluded from the plants. This acceleration reached its maximum in twenty-four hours then decreased to a minimum equivalent to the original rate in about four times this period. The older plump assertion that "light retards growth" continued to be cited without modification by writers of text-books and compendiums. The few investigators who turned attention to the subject have been content with referring to such cyclopedias. Thus Blaauw² says, in discussing positive and negative photogrowth reactions:

¹ MacDonal, "Influence of Light and Darkness on Growth and Development," *Mem. N. Y. Bot. Garden*, 2, pp. 307, 308, 1903.

² "The Primary Photogrowth Reaction and the Cause of the Positive Phototropism in *Phycomyces nitens*," *Kon. Akad. van Wetensch. te Amsterdam. Proc. of meeting*, January 31, 1914.

With regard to the existence of a sharply defined reaction of this kind, practically nothing can be deduced from literature references, at least the general opinion about the influence of light on growth is completely at variance with these facts. In the first place so far as concerns the positive or negative influence of light, the general conception, supported by numerous facts, is that light exercises a retarding influence on growth.

Blaauw's results which are described in the paper mentioned above and in a later paper³ confirm my original thesis that light does not exercise a flat or invariable effect on growth. Furthermore Blaauw's beautifully arranged experiments by which sporangiophores of the mould were exposed to illumination from four or eight sides, with controlled intensities, demonstrate that the first reaction of this organ to a sudden illumination is an accelerated rate of growth, followed by a gradual decrease from which a recovery is made to the original rate. It is to be seen that the general mode of change is similar to that of massive organs deprived of light as described above. American reviewers seem to have been equally ignorant of my earlier experiments, which had the force of rendering the older generalization invalid. Furthermore the indirect effect of light in conditioning differentiations of tissues and thus affecting growth-elongations was pointed out. Blaauw has made an important contribution by his experimental analysis of the action of light on such simple structures as the sporangiophore of a mould.

The elongation or enlargement of a cell or of any structure like that of the sporangiophore of *Phycomyces* may be taken as the expression of inequality between the extensibility of the cell material, and its membrane, and of some internal expanding or stretching force. The osmotic pressure of the contents of the vacuoles, or of solutions filling the protoplasmic interstices has hitherto been relied upon to furnish the necessary force of growth.

Borowikow has recently established a parallel between the growth of certain seedlings in known definite solutions and the hydration of colloids in the same solutions. This author is therefore led to believe that the stretching

³ "Light und Wachstum," *Zeitschr. f. Botanik*, Hft. 8, 1914.

force of growth is not osmotic but hydration pressure, and he relegates osmotic pressure, turgidity and its corollaries to an inconsequential place in the entire matter.⁴

Several features of the growth and hydration of cacti are not without importance in connection with any consideration of this matter. The researches of Richards and of Spoehr at the Desert Laboratory show that the acidity (malic and oxalic) of the sap of cylindropuntias and platypuntias decreases from its maximum at daybreak to a minimum at about 4 p.m. in the open. The decrease has been shown to be due to the conjoint disintegrating action of temperature and chiefly of light. The calibrations made by Mr. E. H. Long (paper now in press) brought out the fact that if small cylinders were cut from the bodies of these cacti in series beginning at daybreak and extending to the period of minimum acidity, the hydration capacity of the pieces increases independently of osmotic pressure throughout the day and is greatest in those which have been taken from the plant at the time when collateral tests would indicate the lowest acidity.

Extensive auxanometric records of *Opuntia Blakeana* made chiefly in March and April show that the growth of the enlarging joints is at a minimum in the morning, with a rapid acceleration parallel with the rising temperature of the open, reaching a maximum about noon and then decreasing to a minimum before 3 p.m. The curves of decreasing acidity and increasing hydration capacity are symmetrical through the range of acidity from N/10 to N/20 according to available data obtained from these plants, and would probably sustain a similar relation in weaker solutions if the acidity were reduced still further.

From the records cited above however it is to be seen that the acceleration of the rate of growth does not follow that of hydration to its customary daily maximum. Whether this divergence is due to a shrinkage following a heightened water-loss is not yet known. An ample supply was available to the absorbing

⁴ Borowikow, "Ueber die Ursachen des Wachstums der Pflanzen," *Biochem. Zeitschrift*, 48: pp. 230-46, 1913.

surfaces within a few cm. of the expanding masses of cells, but local transpiration may have resulted in actual shrinkage. The optimum temperature for this plant is also a feature not yet determined.

The growth of the opuntias therefore takes place during a period of decreasing acidity resulting from the disintegrating action of light and rising temperatures. This statement applies not only to the diurnal behavior of the plants during the growing season, but to the growing season as a whole, which as Dr. H. M. Richards has pointed out in a paper now in press is one of diminishing acidity. The acidities of the cacti are calculated for the sap of the plants. The acidities of N/100 to N/3,000 found by Borowikow to be favorable for hydration and growth were of the culture solution; that of the sap of the seedling used was probably still much lower.

Light and temperature in lesser degree are seen to exercise a totalized releasing effect on growth coincident with reduced acidity and increased hydration, to a certain limit. Beyond this growth rate is checked. Further analytical tests will be necessary to determine the limiting factors.

D. T. MACDOUGAL

DESERT BOTANICAL LABORATORY

PROCEEDINGS OF THE ANNUAL MEETING
OF THE AMERICAN SOCIETY OF
ZOOLOGISTS HELD IN PHILA-
DELPHIA, 1914. II

Multiple Human Births: G. H. PARKER.

Multiple births are well known among human beings and the proportions of twins, triplets, and quadruplets to single births have often been recorded. Instances of five and six children at a birth are very rare but apparently well authenticated. All cases above six are very doubtful. In the *Boston Medical and Surgical Journal*, Volume 10, page 224, 1872, is recorded from Trumbull County, Ohio, a case of eight children at a birth. This very circumstantial account, which has been quoted in numerous books and journals, proves on investigation by the county clerk of Trumbull County to be entirely fictitious.

Comparative and General Physiology

Effect of Electrolytes Upon the Rate of Nerve Conduction in Cassiopea: ALFRED G. MAYER.

Further Studies on the Behavior of Amœba: ASA A. SCHAEFFER.

The Significance of Certain Internal Conditions of the Organism in Organic Evolution: F. H. PIKE AND E. B. SCOTT.

Zoologists, while studying the phenomena of form regulation in animals, have given comparatively little thought to the regulation of internal conditions—the changes in matter and energy in the organisms which underlie the changes of form.

The data accumulated in the physiological laboratories show that in the higher animals there is a regulation, varying within relatively narrow limits, of body temperature, the blood pressure, the tension of carbon dioxide and oxygen, of the concentration of hydrogen and hydroxyl ions, of the osmotic pressure, and of the general composition, quantitative as well as qualitative, of the fluids of the body, brought about by a number of systems and organs of the body.

From the point of view of the physical chemist, the general constancy of internal conditions of the higher organism may be interpreted in terms of chemical equilibrium. If the reactions within the body are of the nature of the "slow" reactions of the chemical laboratory, the constant temperature and the constant physico-chemical concentration of the body fluids would be attended by a speed of reaction within the body which would be, in a considerable degree, independent of the conditions in the environment. The internal mechanisms of the organisms lie at the base of the diminishing effect of the environment, or the greater degree of independence of the animal from the conditions of the environment as the organisms occupy successively higher positions in the evolutionary scale.

Experiments on X-Radiation as the Cause of Permeability Changes: A. RICHARDS.

Some Factors Concerned in the Death of Paramacium at High Temperatures: M. H. JACOBS.

The Effect of Color in the Environment on the Color Changes of Anolis Carolinensis: MANTON COPELAND.

It is well known that the so-called *Florida chameleon*, *Anolis carolinensis* Cuv., becomes green in the dark and almost invariably turns brown in daylight. To test the effect of color in the environment on the color changes in the skin of the lizard, the animals were placed in boxes lined in part with colored paper and exposed to daylight. It was found that the green color was often assumed under such conditions. A yellow environment always induced a change from brown to

green. Green surroundings were nearly as effective in bringing about this reaction, whereas red and blue were much less so. When placed in a white box certain individuals became green. The brown color was assumed when a box lined with black paper was substituted for a color box. The green hue persisted with slight change for several hours when the animal was in the yellow environment.

When a lizard was blindfolded it remained brown in the yellow box, and numerous tests showed conclusively that the organs concerned in receiving light stimuli, which induced a color change in the skin from brown to green, were the lateral eyes.

The Absorption of Fat by Fresh-water Mussels.

E. P. CHURCHILL. (Introduced by Caswell Grave.)

The work was undertaken for the U. S. Bureau of Fisheries with the object of ascertaining whether or not aquatic animals use food which is in solution in the water. Mussels were kept in soap solutions made from olive oil, both unstained and stained with Sudan III. Histological examination of such mussels and of controls revealed the fact that fat is absorbed abundantly and carried over the body by the blood corpuscles and plasma. Sections of mussels kept in fat solutions short periods, as 18 or 24 hours, showed such a heavy loading of fat in the epithelium of gills, mantle and foot that it seemed very probable that the cells of such epithelium absorbed the fat directly from the solution. Mussels with the valves wedged open were suspended over the solution, so that only the ventral part of the foot and mantle were immersed, the mouth and siphons being above the solutions. Examination after some hours of the parts of epithelium so exposed showed more fat than in the epithelium of other parts or in that of the corresponding regions of the control. Fat can be absorbed from solution by the epithelium of intestine and probably outer body walls.

Vision in Flounders: S. O. MAST.

Flounders, especially *Paralichthys* and *Anoxylosetta*, simulate the background to a most remarkable degree. The process of simulation involves changes in shade, in pattern and in color. Since all of these changes are controlled by stimuli received through the eyes, the nature and the degree of simulation of the background constitutes an excellent criterion of vision, in so far as this term may be used in a purely objective sense.

On the basis of this criterion it was found that, in regard to shade and color, vision in fishes is es-

entially the same as it is in human beings. It was also found that these animals distinguish between dots 2 mm. and 3 mm. in diameter respectively, that they recognize dots 1 mm. in diameter but that they do not recognize dots 0.5 mm. in diameter.

By means of a background consisting of a rotating disk which contained alternate black and white sectors, it was found that the fusion-rate of images in flounders corresponds very closely with that in the human being, indicating that in regard to motion vision in fishes is as acute as it is in man.

On a background containing only gray or black and white, no color is produced in flounders regardless of the shade or pattern or the intensity of the light. Simulation in color is consequently dependent upon the length of the waves of the light, not upon differences in its intensity. It therefore strongly supports the contention that fishes have color-vision. This is, moreover, supported by the fact that flounders adapted to a given color tend to select a background of the same color, and the fact that this selection is of such a nature that it can not be accounted for on the basis of difference in the intensity of the light reflected by the different colors. Thus the contention that fishes have color-vision is supported both by the reactions of the animals and by the reactions of the chromatophores in the skin.

Influence of Thyroid Ingredients on Division-rate in Paramæcium: R. A. BUDINGTON AND HELEN F. HARVEY.

Paramæcia of known ancestry were placed in bacterial infusions of known composition. These were kept on hollow slides in moist chambers in the usual manner. To certain slides were added equal amounts of dried thyroid glands taken from types of each of the five main subdivisions of Vertebrata. Besides each thyroid-treated line was carried a control line, two progeny of a single dividing individual being used in the experiment.

The number of individuals resulting from fission in each line was counted each day; at the end of six days the following were the data secured, each figure being the average of three repetitions of the same experiment:

Fish thyroid	70.6
Control	36.6
Amphibian thyroid	112.3
Control	80.0
Reptilian thyroid	135.3
Control	24.3

Avian thyroid	222.0
Control	48.6
Mammalian thyroid	315.3
Control	57.3

The conclusion is that throughout the evolution of the vertebrate phylum, the thyroid has retained certain of its physiological characters intact. The observations previously made by Nowikoff, later by Shumway, on mammalian thyroid influence on *Paramaecium* are thus confirmed, and the significance of the facts extended so as to include the homologous glands of each of the other four classes of vertebrates.

The Effect of the Removal of the Marginal Sense Organs on the Rate of Regeneration in Cassiopea Xamarcana: LEWIS R. CARY.

The results of the investigations of most workers on regeneration has shown that no direct effect of the nervous system upon regeneration could be demonstrated. Zeleny concluded as a result of his work on *Cassiopea* that when the sense organs were removed the animals regenerate sometimes faster and sometimes slower than do specimens with the sense organs intact. Stockard removed the sense organs from one half of a *Cassiopea* disk and insulated the two halves by removing a strip of sub-umbrella tissue so that one half was active, the other inactive, and found that the rate of regeneration was the same in both halves. From these experiments he concluded that muscular activity had no influence on the rate of regeneration.

In a large series of experiments on *Cassiopea* disks prepared in the manner just mentioned I have obtained the following results:

1. When entire disks are used for the experiments those from which the sense organs have been removed may regenerate slower or faster than those retaining their sense organs on account of individual variation in the rate of regeneration.

2. In specimens prepared so that one half is active, the other inactive, the active side (that bearing the sense organs) always regenerates fastest. The difference in rate is particularly noticeable in earlier stages of regeneration.

3. When the sense organs are removed from one half of the disk, but the halves not insulated, the rate of regeneration is the same for both sides. If only a single sense organ remains the results are the same.

4. In a solution made up of sea water to which has been added 15 volumes per cent. of 0.6 M

MgSO₄, the regeneration is equal from both sides, but at the rate of the inactive half of a specimen from which one half the sense organs have been removed.

5. In specimens from which all sense organs have been removed but in which one half is kept in pulsation by means of a trapped wave of contraction, the regeneration is the same for both halves, although the rate of contraction in the active half may be higher than for a half disk on which the sense organs are present.

The rate of metabolism as determined for the writer by Dr. S. Tashiro is higher for the half disk bearing sense organs than for the inactive half, or for the half that is kept in contraction by means of a trapped wave.

The Locomotion of Actinians: G. H. PARKER.

The creeping habits of *Metridium* and *Sagartia* were studied at Woods Hole and of *Condalactis* and *Actinia* at Bermuda. *Metridium* and *Sagartia* creep slowly and in directions which may be in one individual at right angles to its axis of structure, in another coincident with it, and in still another oblique to it. Whether one individual could assume in sequence all these directions was not ascertained for these sea anemones. In *Condalactis* and *Actinia* the creeping was more actively carried out than in *Metridium* and *Sagartia*. A single *Actinia* crept now in the direction of its axis, now at right angles to it, and now in some other direction. There is no reason to suppose that this freedom is not possessed by the other sea anemones. In all the forms studied locomotion was accomplished by a wave-like movement of the foot. This began at the rear edge of the foot and proceeded to the front edge. It was exactly like the direct type of wave seen in the mollusk foot, but could be established temporarily on any axis. In *Condylactis* it required about three minutes for a wave to pass over the foot and with each wave the animal progressed a little over a centimeter in distance.

The Behavior of an Enteropneust: W. J. CZOZIER.

A species of *Ptychodera* found in Bermuda was studied with reference to its movements and sensory reactions. The orderly progression of peristaltic waves on the thorax and abdomen was found to depend upon the continuity of the dorsal and ventral nerve cords. At night the animal responded to general mechanical stimulation by the emission of a phosphorescent material from the collar region. *Ptychodera* showed "differential sensitivity" to light; it was not photographic.

Local reactions were obtained in response to mechanical and chemical stimulation, the order of decreasing sensitivity of the parts of the animal being: proboscis, posterior end, genital pleuræ, the alkaline metals the normal lyotropic series, abdominal surface, collar. For the chlorides of $K > NH_4 > Li > Na$, was found to express their stimulating efficiency; this was mainly a kation stimulation, but in the case of salts ($CaCl_2$, *e. g.*) which did not stimulate strongly, other anions (in this case $Ca(NO_3)_2$) were effective as stimulating agents. Photic sensitivity was readily separated, by exhaustion or anesthetics, from mechanical and chemical; but for the two latter forms of irritability no physiological separation was discoverable. It is therefore suggested that in *Ptychodera* there are generalized receptors open to stimulation by both mechanical and chemical means.

On a Certain Fibrin Reaction Which Occurs in Living Cultures of Frog Tissues: GEORGE A. BAITSSELL.

In living cultures of various tissues of the adult frog there occurs, in many instances, a transformation of the fibrin net of the plasma clot in which the living tissue is embedded. In general the changes which occur first make their appearance when the culture is from two to three days old. During these changes the elements of the fibrin net appear to fuse or consolidate and as a result there are formed a great number of fine wavy fibrils which unite to form bundles of fibers, and these freely intertwine and anastomose as they ramify throughout the area of the plasma clot. The transformation of the fibrin net begins first in the region of the clot which lies in immediate contact with the embedded tissue and gradually extends to the distal regions of the clot until after a time practically the entire plasma clot becomes changed into a tissue greatly resembling that found in various types of connective tissues. Photographs of both living and preserved cultures have been made to show the transformation of the clot and the development of the fibers. Experimental work shows definitely that the fibers arise by a transformation of the fibrin net and are not due to any intracellular action. The work also indicates that the transformation will not take place without the influence of living tissues, although mechanical factors may be introduced which will aid in the formation of the fibers. Various experiments made to determine the true nature of the fibers give conflicting results. The fact, however, that the fibers have also been found

to occur in the fibrin net during wound healing indicates that they play an important part in such a process. Studied histologically with a Mallory stain, there appears to be nothing to differentiate them from regular connective tissue fibers. Work is in progress to determine their final fate and the relation they bear to permanent connective tissue fibers.

Studies on the Phosphorescent Substance of the Fire-fly: E. NEWTON HARVEY.

Dried powdered luminous tissue of the fire-fly will phosphoresce strongly if moistened with water containing oxygen. If first extracted with boiling ether or a mixture of equal parts boiling ether and alcohol for eight hours and the solvent then removed, strong phosphorescence still occurs when water containing oxygen is added to the dry powder residue. Similar results are obtained with hot chloroform and acetone, and cold carbon tetrachloride and toluol.

If oxygen-free water is added to the dry powdered luminous tissue no phosphorescence occurs. If oxygen is then added light is emitted. But if no oxygen be admitted until an hour or more after contact of the powder with oxygen-free water, then phosphorescence does not occur. Salt, acid and alkaline solutions give similar results.

From these experiments we may conclude: (1) that the photogenic material is not a fat or a lecithin; (2) that the photogen or some accessory substance is unstable and decomposes in the presence of aqueous solvents even though oxygen be absent. The change is therefore not oxidative in nature. It is well known that the photogen oxidizes readily in presence of oxygen and is used up with light production.

Dried luminous bacteria give similar results, with this exception, that extraction with chloroform, acetone and a mixture of equal parts boiling alcohol and ether destroys or weakens the powder to phosphorescence. The bacterial photogen is also unstable if the bacterial cell is broken up in the absence of oxygen.

Some Experiments on Fundulus Eggs Aiming at the Control of Monstrous Development: E. J. WEBER.

Starting from the assumption that human and other mammalian monsters found in nature may be due to a pre-uterine or intra-uterine poisoning by the substances found in the blood under pathological conditions of metabolism, such as diabetes, nephritis, jaundice, etc., eggs of *Fundulus hetero-*

clitus were subjected to the action of solutions of urea, butyric acid, lactic acid, sodium glycocholate and ammonium hydroxide. Conclusive results were obtained only with butyric acid and acetone.

The effects of both these substances are very similar. If *Fundulus* eggs are subjected to their influence, they will give rise to a great variety of monsters. Cyclopia, asymmetric monophthalmia and neuroplastic development (microembryones, hemiembryones anteriores) were found to occur most frequently. Not uncommonly is the occurrence of acardia in malformed embryos. In some eggs a heart and rudimentary blood-vessels have developed without the presence of an embryo.

The ear vesicles are very often involved in malformations, their size being enormous, owing apparently to edema. Some locomotor anomalies in embryos, which had hatched, pointed to injury sustained by the semicircular canals.

The rarest in occurrence, but probably the most significant from the standpoint of experimental embryology, were found some cases where all that had developed in the egg was a fragment of brain tissue which had given rise to an eye. This "solitary" eye was found to be almost perfect in some cases, while in others the choroid fissure had failed to close ("coloboma"). Sections of one of these eggs show an eye typical in structure. This would seem to establish the fact of the ability of independent development of the eye.

Reactions to Light in Vanessa lantiopa, with Special Reference to Circus Movements: WM. L. DOLLEY, JR. (Introduced by S. O. Mast.)

The Reactions of the Melanophores of Amblystoma Larvae: HENRY LAURENS.

A Case of the Change of Fat, in Nature, to Calcium Soap: R. W. H. WOLCOTT.

The Balance Between the Hydrochloric Acid of the Stomach and the Sodium Carbonate of the Pancreas in Its Relation to the Absorption and Utilization of Sugar: J. R. MUELLER.

The Electric Nerve Centers in the Skates: ULRIK DAHLGREN. (With lantern.)

Food Reactions of the Proboscis of Planaria: WM. A. KEPNER AND ARNOLD RICH.

The removal of part of the proboscis sheath results in exploratory movements of the proboscis. As the sheath is further removed these exploratory movements become more pronounced. Such movements, however, are not maintained for more than two minutes.

Sectioning the living animal posterior to the

base of the proboscis does not disturb in any other manner the proboscis. By removing anterior parts of the body little disturbance of the proboscis results until the plane of sectioning gets quite near the base of the proboscis, when the latter undergoes either mechanical or autoamputation and leaves the proboscis sheath and for at least ten minutes swims about as an independent organism, ingesting food in a futile manner. The proboscis thus freed frequently turns upon its own body and by ingesting it reduces the body to mere pulp.

It is concluded, therefore, that there is resident in the proboscis an instinct to ingest objects. The inhibitory control of this instinct does not lie in the dorsal ganglion, but in a region of the body anterior to and quite near the base of the proboscis.

Preliminary Report on the Relations Between the Reactions of Rhabdoceres and Their Environments: WM. A. KEPNER AND W. H. TALIAFERRO.

In a previous paper² the authors showed that *Microstoma caudatum* when kept under laboratory conditions shows two physiological conditions. In the first place if they are experimented on a few hours after collection they will distinguish between their aquarium water and 5/100 per cent. ordinary salt solution. However, if they are experimented on over a day after collection they do not make this distinction, thus showing that their physiological condition has been lowered. We, likewise, showed that this lowering of physiological condition is due to the rapid accumulation of bacteria under laboratory conditions.

While experimenting on a number of other species of *Rhabdoceres* we found that some showed this loss of physiological condition just as *Microstoma*, while others showed no lowering of their physiological condition, no matter how long they lived under laboratory conditions.

To find an explanation of these results, which at first seemed contradictory, we investigated the natural habitat of the various animals. Here we found that those animals which showed a lowering of physiological condition lived rather deep under the surface of the pond, on roots, where there were relatively few bacteria. On the other hand those that did not show this lowering of condition lived near the surface, in the presence of a great amount of decaying vegetable matter, and hence a great number of bacteria.

²"Sensory Epithelium of Pharynx and Ciliated Pits of *Microstoma Caudatum*," *Biol. Bull.*, Vol. XXIII, No. 1, 1912.

From these experiments we conclude that those animals that live in the presence of a great number of bacteria can withstand the action of these bacteria, while those that do not, can not withstand this action, or that the natural habitat of the animal is the real conditioning factor in its reactions.

The Rhythmic Pulsation of the Cloaca of Holothurians: W. J. CROZIER.

The cloacal region of pedate holothurians contains within itself the mechanism of its coordinated pulsation. The isolated cloacal end pulsates rhythmically for many hours after its separation from the rest of the animal, and forms a very simple prepared object with which to investigate phenomena of rhythmic movement. The rate of pulsation of the isolated cloacal extremity of *Stichopus marbiti* was found to have a temperature coefficient of about 2.4; it was capable of long continuance in water practically free from dissolved oxygen. The coordinating mechanism was much more powerfully affected by nicotine and atropine than by cocaine or morphine. The duration of pulsation and of irritability to mechanical stimulation in diluted sea water was proportional to about the square of the concentration. The alkaline chlorides preserved pulsation and irritability in the order:

was a more powerful depressant than isomolecular or (Mg-) isonic MgCl_2 . Each one of the salts of sea water was necessary for the continuance of pulsation; this was notably true of MgSO_4 , which led to normal relaxation after systole. Alteration of the C_H from $\rho_H = 8.0$ (normal) to $\rho_H = 6.0$ was sufficient to produce stoppage of pulsation within 5 minutes. The brownish skin pigment was given out under abnormal ionic or osmotic conditions, and afforded some index of permeability changes.

Ecology

Altitudinal Distribution of Plankton Crustacea in Colorado: G. S. DODDS.

In 284 collections from 124 lakes and ponds, at elevations between 4,100 and 12,188 feet, the author found 50 species of Entomostraca. Other records raise the list to 69 species (Phyllopoda 14, Cladocera 35, Copepoda 20). There are 22 species confined to the mountains, 27 found only in the plains, and 20 range more or less widely through both areas. More definitely, there may be recognized four zones, marked more or less clearly

by physiographic, climatic and faunal characters, as follows: Plains Zone, up to 5,400 feet; Foot-hill Zone, 5,400 to 8,500 feet; Montane Zone, 8,500 to 11,000 feet; Alpine Zone, above 11,000 feet. In determining distribution of species and boundaries of zones, temperature seems to be the most important factor.

In climate and fauna, these zones have their nearest geographical equivalents as follows: Alpine zone to Labrador, southern Greenland and extreme north of Russia; Montane and Foot-hill zones to the region north of Lake Superior, Newfoundland, and the main part of Norway and Sweden. The plains zone to the Mississippi valley and the lowlands of Europe, except that the semi-arid climate gives some specialized features.

The Land and Fresh-water Crustacea of Colombia: A. S. PEARSE. (Lantern slides.)

The Vertical Distribution of Some Plankton Protozoa in Wisconsin Lakes: CHANCEY JUDAY.

An Experimental Transmission of Sarcocystis Tenella: JOHN W. SCOTT.

Exceptional Life-histories Among the Unionidae: ARTHUR D. HOWARD.

Glochidia of a fresh-water mussel (Unionidae) were found upon the external gills of *Necturus maculosus*. Eighty per cent. of the collections from the Mississippi were infected. By keeping the necturus alive from October to May the larval mussels were carried through the metamorphosis. The species was still unknown, as it did not correspond with any of the collection of glochidia available and which was supposed to be complete for the region. Study of the ranges of all reported forms revealed one rare species, *Hemilastena ambigua* Say, which might be the adult desired. Gravid mussels containing glochidia were found after considerable search late in September and a comparison with the glochidia in question removed all doubt that they were of the same species. The mussel has the unusual habit of living under flat stones of the flag-stone type. As *Necturus* is known to frequently seek such shelter, the manner of infection is explained.

Anodonta imbecilis has been reported by Sterki as normally hermaphroditic and by Howard as non-parasitic. The embryos have been observed within the egg-membrane up to the attainment of the juvenile stage. They were found to escape from the parental marsupium in late spring and their development followed to a growth of shell many times that of the original glochidium. Observations of the degree of development at various

seasons show a lack of agreement with conditions to be seen in most bradytictic or long period breeders. The following counts illustrate this:

Locality	Date	Eggs				Total
		Early Embryo	Late Embryo	Glochidia	Juveniles	
Moline, Ill.	November 7, 1913	7	3	7	5	22
Fairport, Ia.	May 1, 1914	2	1	5	6	14

Glochidia of *Strophitus edentulus* escaping at various times during the spring from the parent mussel were tested for reactions to sodium chloride, the blood of fishes and contact of fins. A closing reaction was seen in each case. This led to an attempt at normal infection with entire success. The juvenile stage was obtained after a parasitic period of 27 days on the black bass. We have failed, after studies covering two years, to observe development without parasitism in this species. It would seem, therefore, that non-parasitic development as reported for this species is exceptional.

The Isolation of the Okefenokee Swamp Islands, a Segregative or Convergent Factor in Species Formation: ALBERT H. WRIGHT.

The Reaction of Herring and Other Salt-water Fishes to Decomposition Products Normal to Sea-water: V. E. SHELFORD. (With lantern.)

Herring are very sensitive to hydrogen sulfide and carbon dioxide, dying very quickly in small quantities of the former and more quickly than fresh-water species in fatal concentrations of the latter. They turn back upon encountering hydrogen sulfide in sea water and react to hydrogen ions, selecting essential neutrality with a precision showing sensitiveness equal to litmus. When differences in acidity are present they do not react to differences in salinity and density. They react to differences in temperature as small as 0.2° C.

Some Results of the Indiana Lake Survey: WILL SCOTT.

Some Phenomena of Parasitism with Especial Reference to the Unionidae: ARTHUR D. HOWARD.

The usual type of parasitism among the Unionidae is little more than commensalism, apparently. The young mussel or glochidium is embedded in the epidermis of the host, where in the process of metamorphosis little besides protection

and transportation are afforded. In addition to this common and intermediate condition we meet with two extremes; on the one hand, a pronounced dependence upon the host in which considerable growth of the parasite takes place as in the Proptera group. On the other, a complete loss of parasitism with independence of a host in which the glochidium remains in the maternal marsupium until the adult form is reached, as in *Anodonta imbecillis*. The existence of these extremes with intermediate gradations presents quite a range of conditions. The observation of loss of parasitism in *Anodonta imbecillis* brought up the question as to how far the normal appearing glochidia had lost the function for which their structure adapted them. Fresh-cut fins with the blood from live fishes were presented. The snapping reaction was obtained. Infection on fishes was tried without success until glochidia from a number of individuals were used. Infection with complete encystment was then secured. They were not carried beyond this stage.

The recognition of restricted parasitism among the Unionidae has led to the discovery of some interesting ecological relationships, such as *Anodonta pustulosa* to the catfishes, *Quadrula ebena*, to the herring; *Lampsilis anodontoides* to the grapiques, the Proptera group and the Plagiolas to the sheepshead.

The relationship between *Hemilastena ambigua* and *Necturus* is about the only case of which we have anything like a complete knowledge. The others mentioned are only a few of those known from hundreds of species of mussels the hosts of which are not known.

The elimination by fish of inappropriate mussel parasites is a phenomenon which we have often observed. The process seems to be one of catarhal shedding of the external epithelial cells of the fish's gills. Such mechanisms of immunity raise the question as to the perhaps more wonderful adaptations seen in the persistence of the parasitic glochidium when it finds the appropriate host species.

Miscellaneous

Problems of Antarctic Bird Life: R. G. MURPHY.
Some Experiments on Protective Coloration: R. G. YOUNG.

The various theories of protective coloration are based on the assumption of the usefulness of such color. This has frequently been questioned, and lacks as yet adequate experimental support. In order to test the usefulness of color in protecting

animals from their enemies, a series of about 140 experiments, covering a period of six years, has been carried out with various species of caged, and in a few cases with wild birds, to which were fed several kinds of small mammals and insects. The latter were placed upon different backgrounds, with some of which they formed strong contrasts, while others they closely resembled. The birds were then allowed to choose between that prey which resembled, and that which contrasted with its background.

The experiments may be divided into two classes—those in which the birds usually approached their prey swiftly from a short distance, and those in which they approached it slowly, and seized it only after careful inspection. In the former class over 90 per cent. of the combinations chosen were contrasting, while in the latter, the contrasting combinations were chosen but little oftener than the non-contrasting ones.

The experiments indicate that the color of a motionless animal has a decided survival value when it is attacked by birds which approach it swiftly from a distance of even a few feet.

Immunity of Fowls to Cysticerci of Certain Cestodes: J. E. ACKERT

Regeneration of Head Parts in Earthworms After Removal of the Anterior Portion of the Digestive Tube: H. R. HUNT. (Introduced by Herbert W. Rand.)

The object of these experiments was to determine whether the brain and commissures could be regenerated and the stomodeum formed in regenerating earthworms in the absence of the anterior end of the digestive tube. The first three anterior segments of the worms were removed and the digestive tube carefully removed from the first five or six segments posterior to the point where the head was cut off. One hundred and seventy-seven individuals of *Eisenia fetida* and thirty-two individuals of *Helodrilus colliginosus* were used. Seventy-eight worms survived. In six specimens head parts regenerated when the anterior end of the digestive tube was three to five segment lengths from the anterior end of the worm. The six worms fall into three classes: in the first class a stomodeum was formed; in the second class a brain fundement and commissures were regenerated; in the third class a brain fundement and commissures regenerated and a stomodeum was formed.

I am indebted to Professor H. W. Rand, of Harvard University, for many helpful suggestions.

An Interesting Snail from Minnesota and a Problem in Geographical Distribution: R. W. H. WOLCOTT.

Exhibits

During the meeting the following exhibits were made in one of the rooms of the Zoological Laboratory of the University of Pennsylvania:

Exhibits and Demonstrations

Franklin D. Barker: The Absence of Male Reproductive Organs in Trematodes.

J. W. Mavor: The Larval and Post-larval Development of the Coral, *Agaricia Fragilis*, Dana.

Chester H. Heuser: Drawings and Models of the Stomachs of Embryo Cat, Albino Rat, Pig and Sheep.

E. J. Werber: Demonstrations of Some Sectioned and Unsectioned Material of Monstrous Embryos of Fundulus.

of Zoologists

SOCIETIES AND ACADEMIES

THE AMERICAN MATHEMATICAL SOCIETY

THE one hundred and seventy-fifth regular meeting of the society was held at Columbia University on Saturday, February 27, 1918, with an attendance of 39 members at the two sessions. President E. W. Brown occupied the chair, being relieved by Vice-president Oswald Veblen at the afternoon session. The following persons were elected to membership: Professor J. V. Balch, Bethany College; Professor E. J. Berg, Union College; Mr. Millar Brainard, Chicago, Ill.; Mr. L. C. Cox, Purdue University; Mr. C. H. Forsyth, University of Michigan; Dr. H. C. Gossard, University of Oklahoma; Mr. M. S. Knebelman, Lehigh University; Dr. W. V. Lovitt, Purdue University; Dr. L. C. Mathewson, Dartmouth College; Mr. A. L. Miller, University of Michigan; Dr. Bessie I. Miller, Johns Hopkins University; Mr. I. B. Pounder, University of Toronto; Mr. L. L. Steinley, Indiana University; Mr. Child-Chew

Yen, Tangehan Engineering College. Three applications for membership were received.

The following papers were read at this meeting:

M. Fréchet: "Sur les fonctionnelles bilinéaires."

A. S. Hathaway: "Gamma coefficients."

P. H. Lanehan: "Equilog invariants of irregular and regular analytic curves."

B. H. Camp: "Multiple integrals over infinite fields."

A. R. Schweitzer: "On the methods of mathematical discovery."

P. R. Rider: "An extension of Bliss's form of the problem of the calculus of variations, with applications to the generalization of angle."

E. B. Wilson: "The Ziwet-Field note on plane kinematics."

O. E. Glenn: "Ternary transvectant systems."

E. J. Miles: "Note on the application of the calculus of variations to a problem in mechanics."

A. B. Frizell: "The permutations of the natural numbers can not be well ordered."

C. H. Forsyth: "Osculatory interpolation formulas."

J. F. Ritt: "A function of a real variable with any desired derivatives at a point."

J. F. Ritt: "On Babbage's functional equation."

The next meetings of the society will be in Chicago, April 2-3, and New York, April 24. The summer meeting will be held at the University of California and Stanford University, August 3-5.

F. N. COLE,

Secretary

THE BIOLOGICAL SOCIETY OF WASHINGTON

THE 533d meeting of the Biological Society of Washington was held in the Assembly Hall of the Cosmos Club, Saturday, January 9, 1915. It was called to order by President Bartsch at 8 P.M. About 40 members were present.

The minutes of the 531st meeting were read and approved.

Waldo Schmitt, of the U. S. National Museum, was elected to active membership.

Under the heading Brief Notes and Exhibition of Specimens, Dr. L. O. Howard made remarks on the meetings held at Philadelphia during convocation week and Dr. Pilsbry discussed certain aspects of the Hawaiian land-shell problem. The latter said early collecting was done in the valleys, but recent work showed chief home of species to be on ridges. Distribution of forms oc-

curred in groups and there were many instances of Mendelian inheritance between different forms carried out on large natural scale.

The first paper on the regular program was by Wm. Palmer: "An Unknown Fossil." Mr. Palmer exhibited the specimen from the Calvert Cliffs of Chesapeake Bay and hoped members would express views as to its nature. His own view was that it might represent the lower jaw of an unknown turtle. From the same locality other fossils were shown that had previously proved very difficult to identify. Mr. Palmer's communication was discussed by Professor Hay.

The second paper was by Professor Hay: "An Albino Terrapin." The unique specimen was exhibited; it was hatched near Beaufort, N. C.; an attempt was made to raise it, but it lived only a few months. Professor Hay took occasion to show excellent lantern slides of certain interesting crustaceans, especially of *Limnoria lignorum*, wood-boring isopod, and of *Xylotria*, a wood-boring mollusk. Professor Hay's communication was discussed by Messrs. Bartsch, Wilcox, Palmer, Smith, Hopkins and by Miss Rathbun.

The last communication was by M. W. Lyon, Jr.: "Notes on the Physiology of Bats." The speaker stated little was known of exact physiology of bats, but discussed subject from broad standpoint of their physiology of locomotion, of food, adaptation and of special senses. Need of careful experiments on use of, and modern histological work on structure of nose leaves was pointed out. Paper was discussed by Messrs. Howard, Bishop, Hunter, Palmer and Stiles; Mr. Bishop giving an account of a bat roost near San Antonio, Texas, erected with the idea that bats would consume large numbers of malarial mosquitoes. Mr. Hunter stating that an examination of stomach contents of bats showed food of *Nyctinomus mexicanus* consisted of 95 per cent. moths, the rest being carabid beetles, hymenopterous insects and a few crane flies, the only Diptera found, no mosquitoes being observed.

On Tuesday, January 10, 1915, at 8:30 P.M., the Biological Society held a joint meeting with the Washington Academy of Sciences in the auditorium of the National Museum. Dr. Johan Hjort, Director of Fisheries of Norway, delivered an illustrated lecture on "Migrations and Fluctuations of the Marine Animals of Western Europe." About 200 persons were present.

THE 534th meeting of the society was held in the Assembly Hall of the Cosmos Club, Saturday, January 23, 1915, with President Bartsch in the chair and 75 persons present.

Mr. R. A. Ward was elected to active membership.

Under heading Brief Notes, etc., Dr. Johan Hjort, Director of Fisheries of Norway, called attention to the large numbers of herring caught in Norwegian waters during the last few years, most of them belonging to what he termed the "1904 Class." Dr. Hjort attributed the great success of the "1904 Class" to the known lateness of season when it had been spawned and when the plankton was abundant. Early in spring the sea is practically barren of plankton and fish hatching at that time have little food.

The regular program was an illustrated paper by Mrs. Agnes Chase on "Developing Instincts of a Young Squirrel." Mrs. Chase had made careful observations and notes on the bringing up of a young gray squirrel during the past spring and summer. The animal was very young when first acquired by the speaker, needing to be fed on milk with a medicine dropper. Mrs. Chase described its growth, acquisition of squirrel-like habits and instincts. It was not brought up as a pet, but was given every freedom to develop its natural traits. At maturity it met with wild members of its own species, at first returned home, but finally remained away. Mrs. Chase had a few records of the squirrel after it had left; at one time it was seen in company with seven wild squirrels in a strawberry patch where it had once learned to feed. Wild squirrels had not been seen in this patch before and the speaker concluded they had been taught to eat strawberries and shown the place by her former pet.

The rest of the evening was given over to an exhibition of lantern slides on biological subjects. W. W. Cooke showed views of bird life; Dr. Smith, of Japanese silk industry; Wm. Palmer, of seals and birds of Pribilof Islands; Dr. Bartsch, of local birds.

M. W. LYON, JR.,
Recording Secretary

THE NEW ORLEANS ACADEMY OF SCIENCES

THE regular monthly meeting of the New Orleans Academy of Sciences was held at Tulane University on Tuesday, January 19. In the absence of the President, Dr. Irving Hardesty presided. Two papers were presented at the meeting, the first by Dr. W. O. Scroggs, of the history department of Louisiana State University, on "The

Mosquito Kingdom and Henry L. Kinney." According to Dr. Scroggs:

Early in the nineteenth century agents of Great Britain on the Mosquito coast, in eastern Nicaragua, persuaded the native chiefs in this region to recognize one of their number as king, and this half-breed sovereign was persuaded in turn to place his realms under the protection of the British Crown. In the United States it was feared that the British claims thus set up would prove an obstacle to the construction of the interoceanic canal. The Mosquito king meanwhile had made vast grants of his land to enterprising traders along the coast, and these concessions were bought up by an American adventurer, Henry L. Kinney, who undertook in 1855 to colonize the Mosquito coast with Americans and counteract British influences. Kinney's plans were laid on an elaborate scale, but he encountered such opposition from a syndicate of American capitalists at home and from a rival adventurer in Nicaragua, William Walker, that the enterprise failed, and he was financially ruined.

The second paper was by Dr. Gustav Mann, professor of physiology, Tulane University: "What part does water play in our economy?"

Dr. Mann discussed water metabolism. After a general survey of the total quantity of water in individuals of different ages and of that for individual tissues the absorption of water by the intestines, its storage especially in the muscles and its formation inside the body as a result of oxidation of fats, sugars and proteins was gone into. Then the advantages of the circulation of water within the body, the elimination by the salivary glands, the stomach and the intestines and re-absorption of water along with dissolved food substances was pointed out. The work done by Hawk along with Mattill and Hattrem was criticized. There can not be any doubt that an absorption of 4 to 5 liters of water per day greatly helps the digestion of carbohydrates, fats and proteins. It is necessary, however, to constantly bear in mind the amount of salt which is taken with the food. The effect which an excess of salt produces is to render the globulins of the body more soluble while large quantities of water produce the opposite effect. The great advantage of giving nutritive solutions hypodermically and thereby insuring a slow absorption of food radicals in contradistinction to giving salt solutions intravenously for purposes of raising blood pressure was explained. When talking about the elimination of water by the skin, lungs and kidney, the advantage of breathing through the nose and thus keeping the air passages moist to allow foreign material to be caught in the nasal passages was emphasized.

Both papers were the subject of considerable discussion. At the conclusion of the papers, Dr. Mann made an exhibit of brain and thalamus dissections made permanent by infiltration with solid paraffin.

MISS. Intended for publication and books, etc., intended for review should be sent to Professor J. McKean Cattell, Garrison-Hudson, N. Y.

IN preparing a presidential address one has always to meet and answer the same old question that has confronted presidents and retiring presidents of societies ever since presidents and presidential addresses were invented, i. e., Should the effort be primarily to entertain and amuse, or to instruct? I fear that any effort of mine to entertain would be a grievous failure, while an effort to instruct may be but little more successful. Since of two evils we are advised to choose the lesser, I have decided to attempt something more in the line of instruction than entertainment. Instruction is usually regarded, I believe, as a more or less normal function of a specialist, and as modern social and economic conditions have compelled specialization, we must accept the consequence.

The subject of plant pathology properly includes all the phenomena connected with abnormal forms and functions of plants. These abnormal conditions may be grouped in three classes, according to their origin: First, those which are of non-parasitic origin; second, those which are caused by plant parasites; third, those which are caused by animals. Excluding from present consideration diseases directly due to animals, we have left the two classes, non-parasitic and parasitic. By far the greater part of the trouble with which the phytopathologist has to deal are caused by plant parasites. In fact, the greater part of the phytopathology of to-day might quite properly be designated parasitology, and

¹ Address of the retiring president of the Botanical Society of Washington, March 2, 1915.

parasitology is of course only a branch of mycology.

Plant pathology is a subject of very recent development and can scarcely be said to have existed before the middle of the last century. During the period from 1830 to 1850 attention began to be given to this subject. Unger, Wiegmann, Meyen, Raspail and Regel wrote on the diseases of plants. These authors took up the subject from the standpoint of general botany and human pathology rather than mycology. Some very curious ideas prevailed; *e. g.*, it was believed that fungi such as rusts were produced by the puncture of insects (Raspail, 1846). Unger's idea was that certain fungi were outgrowths or modifications of the tissues of the diseased plant. These and earlier works contained various more or less academic discussions of various diseases, based largely upon erroneous ideas of the structure and nature of the parasite as well as the host. As an illustration of how persistent medieval ideas and conceptions are I may cite a recent instance. A correspondent, in explaining the cause of a strawberry disease, states that it is due to "elemental debasement." This reminds one of the "original sin" of the old theology, to which it may perhaps be closely akin.

Under the influence of the important contributions to the knowledge of the cellular structure and tissues of plants, which were made during this period, together with the work of contemporary mycologists, the foundation was laid for a more rational and correct interpretation of plant diseases and parasites.

Since the great majority of plant diseases are caused by fungi, it is quite proper that mycology should be considered the chief cornerstone of this branch of science and should be thoroughly understood by the plant pathologist.

In order to get a proper conception of any subject and to understand and appreciate its present condition and needs, a knowledge of its past history and development is necessary. It is quite appropriate that Florence, the chief seat of learning and the leader in literature, religion, art and science during the Renaissance and beginning of the modern era, with the illustrious names of Dante, Savonarola, Raphael and Michael Angelo should have produced the great botanist, Micheli, who may be justly considered the father of mycology. His great work, "*Nova Plantarum Genera*," published in 1729, was devoted largely to the description and illustration of fungi. This work remained unsurpassed for fifty years and is still recognized as a classic on this subject. Micheli's collections of fungi are still preserved in Florence beside those of Cesalpini. Some of his specimens compare favorably with those of much more recent mycologists.

Following Micheli some twenty-five years later came Battara, also an Italian. During the latter half of the eighteenth century Tode, Hoffman, Batsch, Bulliard and Persoon made important contributions to descriptive mycology. In the early part of the nineteenth century the most distinguished students of the subject were Persoon, Greville, Wallroth, Link, Sowerby, Fries and Corda in Europe, while in America the illustrious Schweinitz laid the foundations of American mycology and took rank among the first mycologists of the world. Following him in this country came Curtis, Ravenel, Peck, Ellis, Farlow and Burrill. Most of the work of the early writers was systematic, and may appear to some of us to be very crude and unsatisfactory, but when we consider the conditions under which they labored and the tools and technique available, it will be found that their work is of as high quality

as could be expected; and is perhaps no more imperfect than ours will appear to mycologists and pathologists a century hence.

Beginning about 1850, there was a great change and improvement in methods and aims in mycological work. The two most conspicuous men of this period were De Bary and Tulasne, who understood a careful comparative study of all that was known of the morphology and physiology of fungi, as well as original investigations of the life histories of the organisms. At the same time Berkeley in England, while devoting his time chiefly to descriptive work, gave much attention to the pathological aspects of the subject and published a very important series of papers in the *Gardener's Chronicle* (1854) on "Vegetable Pathology." In this connection, M. C. Cooke, who has recently passed away, should be mentioned. In America Farlow, Bessey and Burrill first introduced laboratory methods of studying fungi, taking up the work along the lines indicated by De Bary and Tulasne.

NOMENCLATURE

In considering the various phases of mycology in their relation to plant pathology, the subject of nomenclature deserves mention. The plant pathologist as well as the mycologist must use plant names. It is therefore important that this matter should be given careful consideration, in order to devise means of securing as nearly as possible uniformity and stability of usage. Unfortunately at present there is no generally accepted method of accomplishing these ends. It is therefore desirable that pathologists take an active interest in this subject and assist in determining what the fundamental requirements are to secure uniformity and stability and exercise their influence to secure the general adoption of

such regulations. One of the subjects of most fundamental importance in this connection is that of types. It does not seem possible to secure any great degree of uniformity in the use of names until generic and specific names are fixed to definite types. Teachers of mycology and pathologists should consider these matters in a scientific spirit and without reference to personal preference or professional affiliations.

Closely related to this subject is that of terminology in general. There is at present a decided lack of accuracy and uniformity in the use of the various technical terms used in mycology and pathology. With the exception of the rusts, the descriptive terms used have not been accurately defined and coordinated in accordance with our present knowledge; *e. g.*, the term conidium is variously applied to spores produced either on external sporophores or within pycnidia. There is also lack of general agreement and uniformity in regard to the names applied to the various conidial and pycnidial forms of the Ascomycetes. We have such terms as stylospore, spermatium, micro- and macro-pycnospor, micro- and macro-conidium variously applied by different writers.

Of great importance also to the pathologist is the standardizing of methods and technique as far as possible. Though absolute standards in these matters can not well be attained, effort should be made to approximate definite standards as closely as possible.

TAXONOMY

Mycology formerly consisted chiefly of the identification of old species and the describing of so-called new species. This of course was natural and necessary, as there was a vast unknown group of organisms most of which had not been named or described. Unfortunately, the overwhelm-

ing number of the species and the few workers made it impossible for them to devote the time and study to the organisms necessary for satisfactory segregation and description. Species were usually based upon supposed host relations, slight morphological differences or geographical distribution. More recent and thorough studies have shown that these can not be generally depended upon. While one species of a genus may have very definite host relations, the next one may be very indefinite in this respect. In the same way morphological characters which are reliable in one genus or species may be very variable and unreliable in another. The same may be said of geographical distribution. Some species are apparently more or less cosmopolitan, while others are confined to rather limited geographical areas. These facts can only be determined by the most thorough monographic study of each genus or group. Our studies of *Endothia* have brought out these points with great clearness and emphasis. For instance, one of our American species, *E. gyrosa*, extends from the Atlantic coast to the Pacific, and from Connecticut and Michigan to Florida and Texas, whereas its near relative, *E. radicalis*, is restricted to the Appalachian region in America. Such facts are of exceeding importance to the pathologist in determining the nature and possibilities of a parasite.

LIFE HISTORIES

Of still greater importance to pathology, however, is a knowledge of the life histories of parasites. This subject is not only of exceeding importance to pathology, but also to phylogeny and taxonomy in general, and has important bearings on all other branches of mycology. The work of Tulasne and De Bary and their contemporaries was the first important contribution to this subject. Following the discovery

of the pleomorphy of the Ascomycetes there was a tendency on the part of some mycologists to connect up all the various known forms of the so-called Fungi Imperfecti upon the basis of association, similarity or other more or less uncertain evidence. One of the most striking cases of this is furnished by Fuckel in his "Symbolæ Mycologicæ," 1869, where supposed pycnidial or conidial forms are given for the majority of the Ascomycetes listed. In some cases the author was probably correct, but none can be accepted without being verified by cultural studies or other reliable methods. The work of Tulasne, while much more reliable and satisfactory, was based primarily upon the intimate association or union in the same stroma of the different forms of fructification. Much of his work has already been verified by later investigators. Brefeld in his great work on the life histories of the fungi made an exceedingly important contribution to this subject. Unfortunately, many of the conidial and pycnidial forms which he obtained in culture from ascospores can not be identified and connected with certainty with forms already described.

It has already been thoroughly demonstrated that some of the Pyrenomyces have from one to three metagenetic spore forms besides ascospores; e. g., *Sphaerella*, *Glomerella*, *Guignardia*, *Plowrightia*, etc. It is also well known that some of the stages of a fungus may be parasitic and others apparently saprophytic; e. g., many Pyrenomyces mature their perithecia upon dead vegetable matter, while their pycnidial or conidial forms may be actively parasitic. This has led to the classification of most of the Pyrenomyces, whose life histories are not known, as saprophytes. It is clear, therefore, that to even be able to classify an organism satisfactorily as a

parasite or saprophyte its life history must be known.

Here is a vast field for investigation which offers great opportunities for making valuable contributions to knowledge. Thousands of pleomorphic species whose life histories are unknown await the patient and properly equipped investigator. Present culture methods must be improved and new methods probably devised in order to induce many of these fungi to pass through their complete life cycles. It is in this field that we may expect very important discoveries in regard to the factors which determine the production of any particular spore form in the life cycle of a fungus. Of such factors we have very little definite knowledge at present.

PARASITISM

The exact nature of parasitism, its origin and modifications, is naturally of the utmost significance to pathology. This problem can perhaps be attacked with the greatest promise of successful solution in those cases which appear to be near the border line between saprophytic and the parasitic species. If we admit that evolutionary processes are still active, there seems no reason to doubt that parasites are at present in process of evolution. Whether this evolution is brought about by mutation or by a gradual accumulation of slight variations or by some other process or complex of processes not yet discovered, it would seem possible to get further light on this subject by a thorough investigation and comparison of some of the active parasitic Ascomycetes and their near relatives which seem to be saprophytic or only very weakly parasitic. A striking example of this condition of affairs is presented by the genus *Endothia* already referred to. *Endothia parasitica* is a most virulent parasite, whereas its near relative, *E. radicalis*,

which occurs on the same host, shows little or no parasitic tendencies, while some of the other species show slight indications of parasitism.

ECOLOGY

In this connection it may be well to call attention to the great possibilities in the study of the ecology of the fungi. At present, unfortunately, there is little exact knowledge of the distribution and environmental relations of fungi. The exact limits of distribution of but very few species is known, and in fact the exact identity of many species is still doubtful. The question of their host relations is also not well understood except in the case of the rusts, smuts and powdery mildews. Our studies of *Endothia* appear to indicate that, in this group at least, the species have very definite geographical ranges which are not determined by their host relations, but apparently are very intimately associated with climatic and other environmental conditions, as well as competition with other fungi. All these things are of vital interest to the pathologist, especially in connection with the possibilities in the way of the spread of any particular parasite, or in determining the probable behavior of any foreign species which might be introduced. To know what fungi exist in any region and what their natural distribution and host relations are, is of the utmost importance in devising ways and means to prevent their introduction into other countries. In this connection I may quote from Winthrop Sargent in the Final Report of the Pennsylvania Chestnut Tree Blight Commission, 1914, page 12, as he presents the case in a very plain and forceful manner:

In conclusion, it seems necessary to call sharp attention to the real lesson to be learned from the chestnut blight epidemic—viz.: the necessity of more scientific research upon problems of this

character; to be undertaken early enough to be of some value in comprehending, if not controlling the situation. We have seen that the blight might have been kept out of the country in the first place by inspection, or, once in, that it might have been destroyed, or at least checked, before it had gotten widely distributed. But instead it was permitted to enter, and to spread for many years without scientific notice, and for several more years without any organized attempt to control it, or even to study it seriously. Are we doing any better now with reference to the future?

GENETICS

While perhaps not having the same direct bearing upon pathological problems, still it may be worth pointing out that fungi appear to offer one of the simplest and easiest points of attack on the general problems of evolution, such as mutation, variation, and inheritance; in fact, the various problems of genetics. Here we have organisms comparatively simple in structure, either asexual or at least not complicated by possible hybridization and capable of rapid reproduction and cultivation under controlled conditions.

Coming finally to questions of prevention and control of diseases caused by parasites, it is only stating a truism to say that whatever success may be attained in this direction must depend chiefly upon the completeness of our knowledge of the parasite in all its aspects and relations.

Finally, mycologists, pathologists and all real scientists are searchers after truth. This implies not only large opportunities, but also obligations. "Noblesse oblige" is particularly applicable to the scientist. In these days of storm and stress it is, if possible, more important than ever that we should live up to the highest ideals of truth, and make individual and united effort to establish the universal reign of justice, peace, and brotherly love among mankind.

An excellent example of what the scientist should strive to be in all his human re-

lations has been given us by Professor Charles E. Bessey, the distinguished botanist and beloved teacher, whom death has so lately taken from us. He not only sought truth and taught truth, but lived it, making the world not only wiser and richer, but better. May we all leave as noble a record when called to lay life's burdens down.

C. L. SHERAR

EDWARD WESTON'S INVENTIONS

The pioneer work of Dr. Edward Weston is not easy to describe in a few words. His restless inventive activity has been spread over so many subjects, has intertwined so many interlocking problems, that in order to understand its full value, it would be necessary to enter into the intimate study of the various obstacles which opposed themselves to the development of several leading industries which he helped to create: the electro-deposition of metals, the electrolytic refining of copper, the construction of electric generators and motors, the electric illumination by arc- and by incandescent-light, and the manufacture of electrical measuring instruments. An impressive list of subjects, but in every one of these branches of industry, Weston was a leader, and it was only after he had shown the way in an unmistakable manner, that the art was able to make further progress and develop to its present-day magnitude.

But why was Weston able to overcome difficulties which seemed almost unsurmountable to his predecessors and coworkers in the art?

The answer is simple: He introduced in most of his physical problems a chemical point of view—a chemical point of view of his own; a point of view which was not satisfied with general statements, but which went to the bottom of things. He did not

get his chemistry wholesale as it is dispensed in some of our hot-bed-method educational institutions. He had to get at his facts piecemeal, one by one, adjust them, ponder over them—collect his facts with much effort and discrimination; he did not acquire his knowledge merely to pass examinations, but to use it for accumulating further knowledge.

It seems rather fortunate for him that one of the first employments he got in New York was with a chemical concern which made photographic chemicals. This was the time of the wet-plate, when photographers made their own collodion, their own silver bath, their own paper. Whoever went through those delicate operations knew the difficulties, the uncertainties which were caused by small variations in the composition of chemicals or in the way of using them. Photochemistry is excellent experience for any young chemist who is disposed to generalize too much all chemical reactions by mere chemical equations. Whoever has to deal with those delicate chemical phenomena, which occur in the photographic image, knows that many unforeseen facts can not easily be accounted for by our self-satisfying but often superficial generalizations of the text-books.

Weston's tendency to observe small details in chemical or physical phenomena led him to improve the art of nickel-plating and electrolytic deposition of metals to a point where it entered a new era. When he undertook the study of the difficulties in this art, he took nothing for granted, but by close observation he succeeded in devising methods not only of improving the physical texture of the deposit, but for increasing enormously the speed and regularity with which the operations could be carried out; all these improvements are now embodied in the art of electro-typing, nickel-, gold- and silver-plating.

At this time, attempts had already been made for the commercial refining of copper by means of the electric current. But this subject was then in its first clumsy period, far removed from the importance it has attained now amongst modern American industries. Here again, Weston brought order and method, where chaos reigned. His careful laboratory observations, harnessed by his keen reasoning intellect, established the true principles on which economic, industrial, electrolytic-copper-refining could be carried out. Professor James Douglass¹ referred to this fact in a recent address:

I suppose I may claim the merit of making in this country the first electrolytic copper by the ton, but the merit is really due him (Weston) who in this and innumerable other instances, has concealed his interested work for his favorite science and pursuits under a thick veil of modesty and generosity.

The whole problem of electrolytic refining, when Weston took it up, was hampered by many wrong conceptions. One of them was that a given horsepower could only deposit a maximum weight of copper regardless of cathode- or anode-surface. This fallacious opinion was considered almost an axiom until Weston showed clearly the way of increasing the amount of copper deposited per electrical horsepower, by increasing the number and size of vats and their electrodes, connecting his vats in a combination of series and multiple, the only limit to this arrangement being the added interest of capital and depreciation on the increased cost of more vats and anodes, in relation to the cost of horsepower for driving the dynamos.

The electro-deposition of metals forced Weston into the study of the construction of dynamos. Until then, the electric cur-

¹ Commencement address, Colorado School of Mines, *Metallurgical and Chemical Engineering*, Vol. XI, No. 7, July, 1913, page 377.

rent used for nickel-, silver- and gold-plating, as well as for electro-typing, was obtained from chemical batteries. Weston says that it was almost a hopeless task to wean electroplaters from these cells to which they had become tied by long experience and on the more or less skillful use of which they based many of the secrets of their trade.

If the dynamo as a cheap and reliable source of electric current was advantageous for nickel-plating, it became an absolutely indispensable factor for electrolytic copper refining. At that time, the dynamo was still at its very beginning—some sort of an electrical curiosity. It had been invented many years before by a Norwegian, Soren Hjorth, who filed his first British patent as far back as 1855. Similar machines had been built both in Europe and America, but little or no improvement was made until Weston, in his own thorough way, undertook the careful study of the various factors relating to dynamo efficiency.

In 1876, Weston filed his first United States patent on rational dynamo construction, which was soon followed by many others, and before long he had inaugurated such profound ameliorations in the design of dynamos that he increased their efficiency in the most astonishing manner. Heretofore, the dynamos which had been constructed showed an efficiency not reaching over fifteen to forty per cent., gross electrical efficiency, but the new dynamos constructed after Weston's principles increased this to the unexpected efficiency of ninety-five per cent., and a commercial efficiency of eighty-five to ninety per cent. He thus marked an epoch in physical science by constructing the first industrial machine which was able to change one form of energy, motion, into another, electricity, with a hitherto unparalleled small loss. As

the improvements in dynamos depend almost exclusively on physical considerations, and have little relation with the field of chemistry, I shall dispense with going further into this matter. But I should be permitted to point out that the first practical application of electrical power transmission for factory purposes in this country, was first utilized in Weston's factory; the success of this installation induced the Clark Thread Works, also located in Newark, to adopt this method of power transmission for some special work; a method which now has become so universal. For this purpose, Weston had to invent new devices for starting, and for controlling, as well as for preventing injuries to motors by overload.

In Weston's factory also the electric arc was used for the first time in the United States for general illumination.

In fact, from 1875 to 1886, Weston was very energetically engaged with the development of both systems of arc- and incandescent-illumination by electricity. We see him start the manufacture of arc-light-carbons according to methods invented by him, and thus he became the founder of another new industry in America. He continued this branch of manufacture until 1884, at which epoch this part of the business was transferred to another company, which has made a specialty of this class of products, and has developed it into a very important industry. Here again, Weston introduced chemical methods and chemical points of view. Amongst the many objections which the public had against the electrical arc was the bluish color of its light. Women especially complained that the blue-violet light did not bring out their complexion to the best advantage. Weston first tried to use shorter arcs which gave a whiter light, but this was only a partial remedy. He soon found a more radical

and more complete cure by the introduction of vapors of metals or metallic salts or oxide in the arc itself, so as to modify at will the color of the light, and thus he became the inventor of the so-called "flaming arc." It is noteworthy that it took about twenty years before electricians and illuminating engineers became so convinced of the advantages of the flaming arc, that it had to be "reinvented" during these late years, and now it is considered the most efficient system of arc-illumination.

In relation to this invention, it is interesting to quote the following extract of the specifications from his United States Patent 210,380, filed November 4, 1878:

This rod or stick may be made of various materials, as, for example, of so-called "lime glass," or of compounds of infusible earths and metallic salts, silicates, double silicates, mixtures of the silicates with other salts of metals, fluorides, double fluorides, mixtures of the double fluorides, fusible oxides, or combinations of the fusible oxides with the silicates—the requirements, so far as the material is concerned, being that it shall be capable of volatilization when placed on the outer side of the electrode to which it is attached, and that its vapor shall be of greater conductivity than the vapor or particles of carbon disengaged from the carbon electrodes. The foreign material added to the carbon may be incorporated into the electrode by being mixed with the carbon of which the electrode is composed, or it may be introduced into a tubular carbon; but I have found it best to place it in a groove formed longitudinally in the side of the electrode, as shown.

In his endeavors to make the electric incandescent lamp an economic possibility, we see him introduce over and over again, chemical methods and chemical considerations. He first tried to utilize platinum and iridium, and their alloys, which he fused in a specially constructed electric furnace, devised by him, antedating the furnace described by Siemens. This is probably the first electrical furnace, if you will except the furnace which Hare used in his laboratory in Philadelphia.

But these platinum metals showed serious defects aside from their high cost, and by that time, Weston had become so familiar with the properties of good carbon that like other inventors, he became convinced that the ultimate success lay in that direction.

And now we see him join in that race of rivalry among inventors who all engaged their efforts in search of the real practical incandescent lamp. Among this group of men, the names of Edison here in the United States and that of Swan in England, have been best known. To go in the details of this struggle for improvement is entirely outside of the scope of this short review.

Edison succeeded in making incandescent lamp filaments by carbonizing selected strips of bamboo. But even a carbon made of this unusually compact and uniform material was far from being sufficiently regular and homogeneous. Indeed, all the then known forms of carbon conductors had the fatal defect of a structural lack of homogeneity. On account of this, the resistance varied at certain sections of the filament, and at these very spots, the temperature rose to such an extent that it caused rapid destruction of the filament; this is somewhat similar to the chain which is just as strong as its weakest link.

These irregularities in the filament reduced enormously the term of service of any incandescent lamp. Weston tried to solve this difficulty by means of his chemical knowledge. He remembered that as a boy, when he went to visit the gas works to obtain some hard carbon for his Bunsen cell, this carbon was collected from those parts of the gas retort which had been the hottest, and where the hydrocarbon gas had undergone dissociation, leaving a dense deposit of coherent carbon.

In this chemical phenomena of dissociation at high temperature, he perceived a

chemical means for "self-curing" any weak spots in the filament of his lamp. The remedy was as ingenious as simple. In preparing his filament, he passed the current through it while the filament was placed in an atmosphere of hydrocarbon gas, so that in every spot where the temperature rose highest on account of greater resistance, brought about by the irregular structure of the material, the hydrocarbon gas was dissociated and carbon was deposited automatically until the defect was cured, with the result that the filament acquired the same electric resistance over its whole length. But this invention, however brilliant, did not limit his efforts. He had become imbued with the idea that the ideal filament would be an absolutely structureless, homogeneous filament, with exactly the same composition and the same section throughout its whole length. He reasoned that such a filament could not be obtained from any natural products, neither from paper nor bamboo, but that it had to be produced artificially in the laboratory from an absolutely uniform, structureless chemical substance. After various unsuccessful attempts, he finally secured this result by applying his old knowledge of the days when he used to make collodion. He produced a homogeneous, structureless transparent film of nitrocellulose by evaporating a solution of this material in suitable solvents. As he could not carbonize this film on account of the well-known explosive properties of so-called "gun-cotton," he obviated this difficulty by eliminating the nitrate group of the molecule of cellulose-nitrate by means of ammonium-sulphhydrate. This gave him a flexible, transparent sheet, very similar in appearance to gelatine; this material he called "Tami-dine." Such films could be cut automatically with utmost exactitude, producing filaments of uniform section, which then

could be submitted to carbonization, before fastening them to the inside of the glass bulb of the incandescent lamp.

It is interesting to note here that the modern Tungsten lamp, in all its perfection, made of ductile tungsten, is after all, the fullest development of the principle of an entirely structureless homogeneous chemical filament. The Tungsten-filament can stand much higher temperatures than carbon and this property gives it higher lighting efficiency, but the former tungsten filaments of a few years ago, which had a granular structure, had the same defect as the earlier carbon lamps, namely, a non-homogeneous texture and correspondent short life.

While Weston was wrestling with all his electrical problems, and more particularly with the construction of dynamos and motors, he was handicapped continuously by the clumsy and time-consuming methods of electrical measurements which were the best existing at that period. Up till then, these methods had been found good enough for physical laboratories, where the lack of accuracy did not result disastrously in hitting the pocket of the manufacturer, or where time—abundant time for observations and calculations—was always available. But progress in the electrical industries lagged behind the delay and uncertainties caused by electrical measurements. So Weston was compelled to invent for his own use a set of practical electrical measuring instruments. It was not long before some of his friends wanted very badly duplicates of his instruments; before he knew it, he was giving considerable attention to the construction and further development of these instruments. Just about this time, the electric light and dynamo construction enterprise entered into a new period, where they began to develop in large unwieldy commercial organiza-

tions, requiring public franchises and which had to be backed by vast amounts of new capital. In its boards of directors, business men, or financial men and corporation lawyers, became paramount factors and eclipsed in importance the technical or scientific men, who, in earlier days, had almost exclusively contributed to the development of the art.

Following his natural inclinations, Weston soon abandoned his former business connections in order to entrench himself in a field where individuality, science and technology were of almost unique importance, and which he could develop without the necessity of incurring financial obligations beyond what he could master personally. Thus he dropped his connections with the electric light and dynamo enterprises, and we see him now, heart and soul, in another new industry which he created—the art of making accurate, trustworthy and easy-to-use electrical measuring instruments. Did he foresee at that time that this art would attain the magnitude to which he has brought it to-day? Did he dream that his early modest shop was to develop into one of the most remarkably equipped factories in the world; an institution which seems the embodiment of what industrial enterprises may look like in future days, when scientific and liberal-minded management will have become the rule instead of the exception?

In his factory in Newark, Weston seems to have instilled some of his own reliability and accuracy in the minds of the men and women he employs.

In fact, has it occurred to you that even a man with the widest knowledge and the highest intelligence, who is not scrupulously reliable and careful, who is not the soul of honesty personified, could not make honest and trustworthy measuring instruments nor create reliable measuring methods?

What Stas did in chemistry for atomic weights, Weston did for electrical measuring; he created radically new methods of measurement, and introduced an accuracy undreamt of heretofore. Do not forget that his problems were not easy ones. When the British government offered a prize of \$100,000 for the nearest perfect chronometer, the problem of a reliable chronometer involved considerably less difficulties and fewer disturbing factors than any of those encountered in devising and making electrical measuring instruments. But here again, even at the risk of monotonous repeating, I want to impress you with the fact that the success of the methods of Weston was found in almost every case in the application of chemical means by which he tried to solve his difficulties.

When he took up this subject, the scientists, as far back as 1884, accepted implicitly the belief that the definition of a metal and a non-metal resides in a physical distinction; that for metals the electrical resistance increased with temperature, while for non-metals, their resistance decreased with temperature. This was another one of those readily accepted axioms which nobody dared to refute or contest because they were repeated in respectable textbooks. And yet, this unfortunate behavior of metals was the greatest drawback in the construction of accurate measuring instruments. Indeed, on account of the so-called temperature coefficients, all measurements had to be corrected by calculation to the temperature at which the observation was made. This seems easy enough, but it was time-consuming and often it is more difficult to make rapid accurate observation of the temperature of the instrument itself. First of all, the thermometers are not accurate, and have to be corrected periodically, and furthermore, it is not an easy matter to determine rapidly the temperature of a coil or an instrument. Moreover, by the

very passage of the electric current, fluctuating changes in temperature are liable to occur, which would make the observations totally incorrect. All this led to hesitation and slowness in measurements. Weston wanted to correct this defect, but he was told that the very laws of physics were against his attempts. Before he was through with his work, he had to correct some of our conceptions of the laws of physics; now let us see how he did it:

Weston knew that the favorite metal for resistances was so-called German-silver. Strange to say, he was the first one to point out to the Germans themselves that "German-silver" is a word which covers a multitude of sins, and that the composition of German-silver varies considerably according to its source of supply. The result was that he soon proposed a standard-copper-and-nickel-and-zinc-alloy containing about 30 per cent. of nickel, and which had a resistance of almost twice that of ordinary German-silver and a much lower temperature coefficient. Not satisfied with this, he took up the systematic study of a large number of alloys. The first batch which he undertook to study amounted to more than three hundred different alloys. Since that time, he has considerably increased this number, and is still busy at it. Every one of these alloys he made himself in his laboratory, starting from pure materials, and controlling the whole operation from the making of the alloy to the drawing of wires of determined size. By long and repeated observations, on which many years have been consumed, he was able to determine the electrical behavior of each one of these alloys at different temperatures. After awhile, he began to observe remarkable properties in some manganese alloys he compounded. He managed to produce an alloy which had sixty-five times the resistance of copper. But getting bolder and

bolder, he strove to obtain an alloy which had no temperature-coefficient whatever. He not only succeeded in doing this, but finally produced several alloys which had a *negative* temperature-coefficient. In other terms, their resistance, instead of increasing with rise of temperature, decreased with increasing temperature. He also showed that the resistance of these alloys depended not only on their composition, but on certain treatments which they undergo, for instance, preliminary heating. And since that day, the physicists have had to bury their favorite definition of metals and non-metals. The present generation can hardly realize what this discovery meant at that time. I could not better illustrate this than by reminding you of the fact that in 1892, at the meeting of the British Association for the Advancement of Science, where it was urged to found an institution similar to the Deutsche Reichsanstalt, Lord Kelvin said in his speech:

The grand success of the Physikalische-Reichsanstalt may be judged to some extent here by the record put before us by Professor von Helmholtz. Such a proved success may be followed by a country like England with very great profit indeed. One thing Professor von Helmholtz did not mention was the discovery by the Anstalt of a metal whose temperature coefficient with respect to electrical resistance is practically nil; that is to say, a metal whose electrical resistance does not change with temperature. This is just the thing we have been waiting for for twenty or thirty years. It is of the greatest importance in scientific experiments, and also in connection with the measuring instruments of practical electric lighting, to have a metal whose electrical resistance does not vary with temperature; and after what has been done, what is now wanted is to find a metal of good quality and substance whose resistance shall diminish as temperature is increased. We want something to produce the opposite effect to that with which we are familiar. The resistance of carbon diminishes as temperature increases; but its behavior is not very constant. Until within the last year or so nothing different was known of metals from the fact that elevation of temperature had the ef-

fect of increasing resistance. The *Physikalische-Anstalt* had not been in existence two years before this valuable metal was discovered.

Then followed this colloquy:

PROFESSOR VON HELMHOLTZ. The discovery of a metal whose resistance diminished with temperature was made by an American engineer.

PROFESSOR AVETON. By an Englishman—Weston.

LORD KELVIN: That serves but to intensify the position I wished to take, whether the discovery was made by an Anglo-American, an American-Englishman, or an Englishman in America. It is not gratifying to national pride to know that these discoveries were not made in this country.

The misinformation of Kelvin was due to the fact that after the Weston patents had been published, his alloy was called *wanganin* in Germany, and a good deal of publicity had been given to its properties with scant reference to its real inventor, an occurrence which, unfortunately, is not infrequent not only among commercial interests but in technical or scientific circles as well.

No less important was the invention of the Weston cell, which in 1908, by the international commission for the establishment of standards of electrical measurements, has become the accepted universal practical standard for electromotive force. Here again, this physical standard was obtained by chemical means.

Until Weston researched on standard cells, the Clark cell had been the standby of the electricians and electrochemists of the world, as the standard of electromotive force. It required the keen analysis of a Weston to ascertain all the defects of this cell and to indicate the cause of them. Later, he drew from his careful chemical observations, the means to construct a cell which was free from the defects of its predecessors—a cell that had no temperature-coefficient and had no "lag."

He detected that the choice of a saturated solution of sulphate of zinc in which

was suspended an excess of crystals of this salt, was an unsuitable electrolyte and one of the principal causes why the indications of the Clark cell varied considerably with the temperature. It is true that this could be obviated by placing the cell in a bath of constant temperature. But this involves new difficulties due to the proper determination of the real temperature. Furthermore, there is always a "lag" in the indications due to the fact that at varying temperatures it requires a certain time before the solution of the salt has adjusted itself to the coefficient of saturation for each newly acquired temperature. By studying the comparative behavior of various salts at different temperatures, he came to the conclusion that cadmium-sulphate is more appropriate and this was one of the several important improvements he introduced in the construction of a new standard of electromotive force.

Dr. Weston assures me that he has succeeded in making his alloys to show only a change of one millionth for a variation of one degree centigrade. The metallic alloys he discovered are used practically in nearly all kinds of electrical measuring instruments throughout the world. Weston instruments and Weston methods are now found in all properly equipped laboratories and electrochemical establishments of the world. On a recent trip to Japan, I saw them in the University of Tokio, as well as in the Japanese war museum, where their battered remains attested that the Russians used them on their captured battleships. I have worked in several laboratories in Europe equipped with instruments said to be "just as good" as those of Weston, but in most instances, they were imitations of Weston instruments and it was significant that they kept at least one Weston instrument to be used to correct and compare their national product.

Like many inventors, Weston has been engaged extensively in patent litigation. To uphold some of his rights, he had to spend on one set of patents nearly \$400,000, a large amount of money for anybody, but as he told me, he begrudges less the money it cost him than all his valuable time it required—a greater loss to an inventor thus distracted from his work. What is worse, most of this litigation was so long-winded that when finally he established his rights, his patents had aged so much that they had lost, in the meantime, most, if not all, of their seventeen years' terms of limited existence. And here I want to point out something very significant. In the early periods of his work, between 1873 and 1886, Weston took out over three hundred patents. Since then, he has taken considerably less, and of late, he has taken out very few patents—after he became wiser to the tricks of patent infringers. Formerly, as soon as he published his discoveries or his inventions, in his patent specifications, he was so much troubled with patent pirates that instead of being able to attend to the development of his inventions, he was occupied in patent litigation. As an act of self-preservation, he has had to adopt new tactics. He now keeps his work secret as long as possible, and in the meantime, spends his money for tools and equipment for manufacturing his inventions. In some instances, this preparation takes several years. Then by the time he sends any new type of instruments into the world, and others start copying, he has already in preparation so many further improvements that pretty soon the next instrument comes out which supersedes the prior edition. He had to utilize these tactics since he found how impractical it was to rely on his patent rights for protection. That inventors should have to proceed in this way is certainly not a recom-

mendation for our patent system; it kills the very purpose for which our fundamental patent law was created, namely, *the prompt publication of new and useful inventions.*

L. H. BAEKELAND

NOTE ON THE ORBITS OF FREELY FALLING BODIES

IN No. 975, Vol. XXXVIII, N.S. (September 5, 1913), of this journal, I gave a semi-popular account of an investigation on "The orbits of freely falling bodies" published in Nos. 651, 652 of the *Astronomical Journal*, August 4, 1913. Soon after the appearance of these papers several correspondents challenged the result I derived for the meridional deviation of the falling body, all of them maintaining that this deviation is toward the equator instead of away from it, as I had concluded. Being preoccupied with affairs somewhat remote from the fields of mathematical physics, I have not been able to give this apparent discrepancy adequate attention, although its origin was indicated in an informal communication to the Philosophical Society of Washington in April, 1914.

In the meantime, two noteworthy contributions to the already extensive literature of this subject have been published by Professor F. R. Moulton¹ and by Professor Wm. H. Roever,² respectively. These contributions are not only important for originality of methods and for painstaking attention, especially to mathematical details, but they may seem to the casual reader to have exhausted the subject by demonstrating in the most approved mathematical fashion of our day that the postulates

¹ "The Deviations of Falling Bodies," *Annals of Mathematics*, Second Series, Vol. 15, No. 4, pp. 184-94, June, 1914. This investigation is specially remarkable in that but one kind of latitude is used. It is likewise remarkable in that no explicit statement is made as to which of the various latitudes (astronomic, geocentric, geodetic or reduced) is used.

² "Deviations of Falling Bodies," *Astronomical Journal*, Nos. 670-672, pp. 177-201, January 22, 1915.

adopted and the results derived are at once unique, "necessary" and "sufficient." Both authors insist with much particularity that the discrepancy between us is due to superior methods of approximation followed by them in integrating the fundamental equations of motion, since we all agree on the forms of these equations.

But the subject is not thus easily disposed of. A sense of humor should lead us to inquire whether the parties concerned have all solved the same problem. The answer to such an inquiry in this case is that while all have ostensibly treated the same problem, two different problems have actually been solved. We have thus developed a fresh illustration of a common danger in mathematical physics, namely, that of fixing attention on mathematical perfection before adequate regard has been given to physical requirements.

It would be out of place in the columns of this journal to enter into a review of the details of the investigations of Professor Moulton and Professor Roever. Such a review is, in fact, neither desirable here nor essential in a technical publication. The source of the discrepancy referred to is so evident that it needs only to be stated to be appreciated; and once stated there is no ground for controversy in this part of the subject. It appears desirable, however, to refer in some detail to the general considerations involved in deriving the orbits of falling bodies as well as to those special considerations which determine meridional deviations. For this purpose it will be essential in a limited degree to use the abridged language of analysis.

But before adducing these considerations I wish to plead guilty to an oversight in reading Professor Roever's earlier papers* and to submit a brief of extenuating circumstances. At first reading of these papers it appeared to me that he had neglected terms involving the square of the angular velocity of the earth in his equations of motion of the falling body.

* "The Southerly Deviation of Falling Bodies," *Transactions of the American Mathematical Society*, Vol. XII, pp. 335-53. "The Southerly and Easterly Deviations of Falling Bodies for an Unsymmetrical Gravitational Field of Force," *Ibid.*, Vol. XIII, pp. 469-490.

These terms do not appear explicitly in those equations, but only implicitly through a special potential function used by him for the first time, apparently, in this connection. Not being able to follow his derivation of these equations (if, indeed, he may be said to have derived them in the mechanical sense), I assumed them to be identical in meaning, as they are in form, with those published by several earlier writers. This assumption was supported by uncertainty as to meaning and by lack of homogeneity of his expression for the potential function introduced on page 342 of his first paper; and still more by his identification of astronomic with geocentric latitude (on p. 339, same paper) by means of the loose phrase "with sufficient approximation." A similar lack of "accuracy and precision" will be found in several parts of his latest paper cited above. See, for example, his equations (j), wherein he confounds geocentric with reduced latitude; also p. 199, where he identifies his equations (38) and (41) with my equation (26) and makes with respect to them the surprising statement that "it is, of course, evident that this function corresponds to some distribution of revolution" in the earth's mass. Concerning the absence of validity for this latter statement some remarks are made below.

Now, to account for the discrepancy in question, namely, our differing values for the meridional deviation of the falling body, it is only essential to observe that two different surfaces of reference have been used. Professors Moulton and Roever have referred the motion to a geoid specified by a certain approximate potential function, while I have referred the same motion to Clarke's spheroid of revolution (of 1866), which is determined by certain axes (a , b) dependent on geodetic measurements. These surfaces are not coincident to the order of approximation adopted by either party, and the discrepancy developed appears to be both "necessary" and "sufficient" to restore confidence in the mathematical mills of all concerned.*

* It has been known since the earlier writings of Airy that the geoid and the spheroid are not coincident, but I was not aware that their inclination

To put this statement in a clearer form for the mathematical reader, let V denote the gravitational potential per unit mass at a point outside, or on, the earth, and let r and ψ denote, respectively, the radius vector and the geocentric latitude of that point. Then, if ω denotes the angular velocity of the earth and if the point (r, ψ) is attached to and rotates with the earth, the expression

$$V + \frac{1}{2} \omega^2 r^2 \cos^2 \psi$$

is the potential per unit mass at that point due to the attraction and to the rotation of the earth. Calling this expression U ,

$$U = V + \frac{1}{2} \omega^2 r^2 \cos^2 \psi = \text{constant} \quad (1)$$

specifies a family of equipotential surfaces about the earth. Thus, for example, $U = \text{constant}$ specifies the sea surface, provided V , r , ψ have appropriate values, and this surface, which may be imagined to extend through the continents, is called the geoid. Similarly, corresponding surfaces above and below the sea surface are geoidal and may be used, like the sea level, as surfaces of reference.

Adopting for the moment the simpler hypothesis that the shape of the geoid does not depend on longitude, the divergence from parallelism of the geoid (1) and the spheroid (a, b) may be defined in the following manner. Since the linear acceleration components along and perpendicular to the radius vector r at the point (r, ψ) of the geoid $U = \text{constant}$ are, respectively,

$$\frac{\partial U}{\partial r} \quad \text{and} \quad \frac{\partial U}{r \partial \psi},$$

the tangent of the angle between r and the normal to the geoid at the same point is given by the quotient of the second by the first of these partial derivatives.*

The angle thus derived is the difference between the astronomical latitude, ϕ , say, and the geocentric latitude ψ of the point (r, ψ) . could figure sensibly in the orbits of falling bodies when my first investigation of these orbits was published.

* To terms of the order of ω^2 inclusive this tangent, using the notation of my paper cited above, is

$$\frac{\frac{1}{2} r \left(\omega^2 + \frac{3g}{r^3} \right) \sin 2\psi}{\frac{\alpha}{r^2} + \frac{3g}{2r^4} (1 - 3 \sin^2 \psi) - \omega^2 r \cos^2 \psi}.$$

Using the data for V and r adopted in my paper cited above, it is found that the general value of this difference is to the first order of approximation, and in seconds of arc,

$$\phi - \psi = 688'' \sin 2\phi. \quad (2)$$

On the other hand, the difference between the geodetic latitudes ϕ , say (determined by the normal to the spheroid (a, b)), and the geocentric latitude of the same point, is to the same order of approximation

$$\phi - \psi = 700'' \sin 2\phi. \quad (3)$$

There is thus a systematic difference between these two quantities, since the residuals $(\phi, -\phi)$, or the so-called plumb-line deflection in the meridian, are assumed to be of compensating plus and minus magnitudes in determining the spheroid (a, b) . Otherwise expressed, this systematic difference is such as to make the value of the meridional deviation of the falling body vanish to terms of the order of ω^2 inclusive, adopted in my investigation, if reference is made to the geoid instead of to the spheroid; and to this order of approximation the discrepancy is completely accounted for.

It is evident that we may not discard either in favor of the other, of the two surfaces of reference giving rise to this discrepancy, since their departure from coincidence is an index of our ignorance of the geoid especially and to a less extent also of the spheroid used. The geoid specified by equation (1) is obviously less well known than the spheroid, since an assumption must be made concerning the distribution of density in the earth before the moments of inertia which determine the geoid can be computed. Thus the relation (3) is known with less precision than the relation (2); but it is now clear that a complete treatment of the problem in question requires that both of these relations be taken into account along with the additional relations $(\phi, -\phi)$ and $(\lambda, -\lambda)$, say, or the plumb-line deflections in latitude and longitude, respectively, at the point (r, ψ, λ) . That considerable uncertainty attaches still to the relation (3) is indicated by the range in the following values for the coefficient of $\sin 2\phi$ derived by some earlier and by some more recent writers in geodesy.

Bessel, 1841.....	690.6"
Clarke, 1866	700.4"
Harkness, 1891	688.2"
Hayford, 1909	695.8"

It appears essential in this connection to call attention to a common misapprehension with respect to the earth which Professors Moulton and Roever have helped to disseminate by their able contributions to the subject before us. The potential function V which appears in equation (1) above, may be developed in a series of spherical harmonics whose first three terms are given in the second member of the following equation:

$$V = \frac{Mk}{r} + \frac{k}{2a^2} [C - \frac{1}{2}(B+A)](1 - 3\sin^2\psi) + \frac{3k}{4a^2} (B-A) \cos^2\psi \cos 2\lambda. \quad (4)$$

In this r , ψ , λ are, respectively, the radius vector, geocentric latitude and longitude of the point, outside the earth, to which V applies. M is the mass of the earth, k is the gravitation constant and A , B , C are in order of increasing magnitude the moments of inertia of the earth with respect to a set of principal axes originating at its centroid. C is commonly said to be the moment with respect to the axis of rotation of the earth, but in these days of "variation of latitudes" and of "mathematical rigor," it should be said to apply to the axis of figure nearest the axis of rotation. A and B are then the moments with respect to the principal axes in a plane through the centroid and normal to the axis of C , or in the plane of the equator as we commonly say.

The expression (4) has very remarkable properties. It is equation (26) of my paper cited above. The value of V is the same whether the latitude ψ is positive or negative; and dependence on longitude vanishes if $B=A$. With respect to this equation Professor Moulton remarks "If the rotating body is a figure of revolution about the axis of rotation whose density does not depend upon the longitude, the function V can be developed as a series of zonal harmonics in the form

$$V = \frac{\alpha}{r} + \frac{\beta}{r^3} (1 - 3\sin^2\psi)."$$

A similar remark with regard to this expression has been quoted above from Professor Roever, the inference being, apparently, that in some manner the expression (4) limits the distribution of the earth's mass to one of revolution. As a matter of fact, however, the expression (4) implies no such restriction; on the contrary, it applies equally to a body of any form and of any distribution of density, the sole requirement being that the point (r , ψ , λ) lie at a distance from the centroid of the body equal to or greater than the greatest distance of any element of mass in the body from the same point. The considerations which permit us to assume $(B-A)$ small, or possibly negligible, in this and other problems of geodesy, must depend, unfortunately, on other sources of information than the expression (4). Some attention to these considerations was given in each of my papers referred to in the first paragraph of this note.

Without going further into the subject at this time it may suffice to remark that it now appears illusory except as a mathematical exercise to push the solution of the differential equations of motion of a falling body to terms involving the second derivatives of V without including the third term in the right-hand member of (4), without taking account of the known relation between these derivatives, and without taking account of plumb-line deflections, which often exceed the discrepancy shown by equations (2) and (3).

R. S. WOODWARD

February 22, 1915

ARTHUR VON AUWERS

THE problems that confront the astronomer differ from those with which workers in other departments of science are engaged in many important particulars, but in none more than in the magnitude of the data involved. So great is the number of the stars, so vast, both in space and in time, the scale of their motions, that in general it transcends the powers of an individual, or even of a single observatory, to collect, within the span of a lifetime, the materials for comprehensive studies, or to collate and discuss them. Cooperation is probably

more essential to progress in astronomy than in any other science.

The earliest example of cooperation on a large scale in astronomical research was the proposition brought forward by Argelander and his associates, half a century ago, for the formation of a great catalogue of all the stars to the 9th magnitude in the northern sky. At the meeting of the *Astronomische Gesellschaft* in 1869, when, after four years of preliminary discussion, the project was formally initiated, the plan of work adopted was the one presented by Dr. Arthur Auwers, a young astronomer, who, three years earlier, had been elected to membership in the Berlin Academy of Sciences to fill the place left vacant by the death of Encke. In view of Auwers's youth—he was then only 31—this was a notable recognition of his ability. But even more significant was the fact that to him was also entrusted the all-important duty of preparing the system of fundamental star places which provided the foundation for the entire work.

It is impossible, without running unduly into technicalities, to give an adequate idea of the difficulties attending the construction of such a fundamental system of star places. It must suffice to say that it requires the highest order of ability, a profound grasp of the principles of gravitational astronomy, a comprehensive knowledge of star catalogues, rare judgment, and a mastery of detail that is given to but few minds. How well qualified Auwers was for the responsibility placed upon him is evident from the fact that the fundamental system he elaborated more than 40 years ago is adopted, in all its essentials, as the foundation of the greater part of the most refined meridian circle work of the present day.

His connection with the "*Astronomische Gesellschaft* Catalogue" did not end with the service I have described. In addition, he undertook the observation of one of the sections or "Zones" of the catalogue—producing a model work—and was soon made chairman of the commission in charge of the entire project—a position he held to the date of his death, January 24, 1915. Its success, therefore, is in large measure due to his careful planning and wise guidance. Long before his death he had

the satisfaction of seeing the original catalogue completed by contributions from no less than twelve great observatories in Europe and America, and of having the plan extended, again under his direction, well into the Southern Hemisphere.

G. F. J. Arthur Auwers was born in Göttingen in 1838 and received his early education in the schools of his native city. His interest in astronomy was manifested when he was still a mere boy, and even before he received his doctor's degree at Königsberg in 1862, he had made many important contributions to it both by observations and by theoretical investigations. His dissertation for the doctorate, on the variable proper motion of Procyon, placed him at once in the front rank of astronomers. In this research he struck the keynote of his future life-work, "the treatment of all questions concerning the positions and motions of the stars."

I shall not attempt even to enumerate his many contributions to this department of astronomy. His services to the A. G. Catalogue have already been mentioned. It must suffice to describe briefly one other research, in many respects his most important—the new reduction of the Bradley stars.

The fundamental data upon which all studies of the mechanics of the stellar universe depend are the positions of the stars on the celestial sphere, their apparent motions on this sphere (technically, their "proper motions"), their radial velocities and their distances. The first two of these elements are derived from the star catalogues based on meridian observations. One of the most important of all star catalogues is that based upon the observations of Bradley, at Greenwich, about the middle of the eighteenth century, for these observations were the first that are at all comparable in system and in accuracy with those of modern times, and they were also superior to those of his successors for fully half a century. As the time element is of the first consequence in the derivation of stellar proper motions, Bessel, who in 1819 made the first reduction of the Bradley observations, was fully justified in giving his work the title "*Fundamenta Astronomiæ*." Excellent as Bessel's work was,

the rapid progress of astronomy in the next half-century led to a more accurate knowledge of the fundamental astronomical constants and to more refined methods in the reduction of meridian observations, and it also became evident that some of his assumptions respecting Bradley's instrument were erroneous. A new reduction was therefore highly desirable and this was undertaken by Dr. Auwers in 1866. He brought all his skill and special knowledge into play and spared no pains to insure the utmost accuracy in his work. The result of the ten years' labor it involved has been well called a "masterpiece and a model." The Auwers-Bradley catalogue at once became the starting point for all discussions of proper motions—a position it will probably hold for all time.

His fundamental system of star places, the Auwers-Bradley catalogue, and his other work in related fields, will form Auwer's most enduring monuments, but they are far from comprising the full measure of his activities. Thus, he was chairman of the German Commission for the determination of the solar parallax from the transits of Venus in 1874 and in 1882. He took the leading part in preparing the observing programs, conducted in each year one of the expeditions sent out by the government, and personally directed the elaborate discussion of all the results—a truly monumental work which fills six large quarto volumes.

From 1878 to 1912 Auwers held the position of Secretary of the Section for Mathematics and Physics in the Royal Prussian Academy of Sciences (Berlin Academy) and his tactful conduct of the manifold duties of this office, together with his unselfish and tireless devotion to the interests of the academy were gratefully acknowledged by his colleagues at the meeting of June 25, 1912, when they celebrated his jubilee—the fiftieth anniversary of his graduation as doctor of philosophy.

He founded the bureau of the "History of the Sideral Heavens" (*Geschichte des Fixsternhimmels*) whose object it is to collect all of the meridian observations of stars since Bradley's time and to combine them into a single systematic catalogue. He was a member of the commission charged with the organi-

zation of the Astrophysical Observatory at Potsdam, and assisted in the supervision of its construction and of its management in its early years. He was also the first president of the International Association of Academies.

Auwers's commanding position in his chosen science was fully recognized in his own country and throughout the world. His own government gave him the title *Wirklicher Geheimen Ober-Regierungsrat*, and at the time of his death he was *Kanzler des Ordens pour le mérite für Wissenschaft und Künste*. For more than twenty years before his death he had been a member of the seven leading National Academies of Science in Europe and America, a distinction in which but two other astronomers of his generation shared—Newcomb and Schiaparelli. In 1888, he was awarded the gold medal of the Royal Astronomical Society of London, in 1891, the Watson gold medal of our National Academy, and in 1899, the Bruce gold medal of the Astronomical Society of the Pacific. His death marks the passing of one of whom Newcomb wrote, nearly twenty years ago, "To-day, Auwers stands at the head of German astronomy. In him is seen the highest type of the scientific investigator of our time." These sentences well express the judgment of all astronomers at the present day.

March 22, 1915

R. G. AITKEN

SCIENTIFIC NOTES AND NEWS

A MEETING to commemorate the life and scientific work of the late Charles Sedgwick Minot was held on March 17, in the hall of the Boston Society of Natural History. As president of the society since 1897, Dr. Minot had taken great interest in its welfare and growth, and it was due in large part to his efforts that the society has undertaken the study and exhibition of the natural history of New England as its special field. At the meeting addresses were made by Dr. Henry H. Donaldson, of the Wistar Institute of Anatomy and Biology, and Dr. Charles W. Eliot, of Cambridge. Dr. Donaldson especially dwelt upon Minot's early interest in natural history and his scientific career. Dr.

Eliot brought out particularly his great accomplishments for Harvard University in the development of teaching and research in the medical school, and emphasized the remarkable personal qualities that fitted him for this work.

THERE was printed in SCIENCE last week a list of the fifteen candidates selected by the council for election into the Royal Society. The *British Medical Journal* gives information in regard to their positions and work which we reproduce. The men are: Dr. F. W. Andrewes, professor of pathology in the University of London and pathologist to St. Bartholomew's Hospital; Dr. A. W. Conway, professor of mathematical physics, University College, Dublin; Mr. L. Doncaster, superintendent of the University Museum of Zoology, Cambridge, well known for his researches into the Mendelian hypothesis; Mr. J. Evershed, director of the Solar Physics Observatory, Kodaikanal, India; Dr. Walter Morley Fletcher, secretary of the Medical Research Committee established under the Insurance Act; Mr. A. G. Green, professor of tinctorial chemistry, University of Leeds; Mr. H. H. Hayden, director of the Geological Survey of India; Dr. James Mackenzie, whose researches into the action of the heart in health and disease have made his name well known to the profession; Dr. J. C. McLennan, professor of physics, University of Toronto; Dr. A. T. Masterman, fisheries inspector; Dr. G. T. Morgan, professor of chemistry in the Royal College of Science, Dublin; Dr. C. S. Myers, director of the laboratory of experimental psychology, Cambridge; Mr. G. O. Simpson, imperial meteorologist, India; Mr. A. A. Campbell Swinton, one of the early workers with the X-rays and wireless telegraphy, and Mr. A. G. Tansley, lecturer on botany, University of Cambridge.

THE dedicatory exercises of the new buildings of the Washington University Medical School will be held April 29 and 30. According to the *Journal* of the American Medical Association the exercises include, in addition to the various entertainments, addresses by the dean of the medical school, Dr. Eugene

Lindsay Opie; by Dr. William Henry Welch, Baltimore, of Johns Hopkins University; President Abbott Lawrence Lowell, of Harvard University; President Henry Smith Pritchett, of the Carnegie Foundation for the Advancement of Teaching; President George Edgar Vincent, of the University of Minnesota; Drs. William Townsend Porter, Robert James Perry, Fred Towsley Murphy and George Dock, of Washington University, Abraham Flexner, assistant secretary of the general education board, and Major-General William Crawford Gorgas, surgeon-general U. S. Army. On April 28, exercises in commemoration of Dr. William Beaumont will be held, including the presentation of the manuscripts and letters of William Beaumont to Washington University Medical School, the acceptance of the gift by the chancellor of the university, and addresses on "William Beaumont as a Practitioner," by Dr. Frank J. Lutz, and "William Beaumont as an Investigator," by Dr. Joseph Erlanger.

ACCORDING to *Nature* the Imperial Society of Naturalists of Moscow has removed the names of Professor Haeckel and Professor Ostwald from the list of members on account of their having signed the address, "To Civilized Nations."

PROFESSOR VICTOR HENSEN, the well-known physiologist of Kiel, has celebrated his eightieth birthday.

DR. JOHN R. MURLIN has been granted leave of absence from Cornell University Medical College, New York City, to accept a temporary appointment as biochemist at the Pelagra Hospital of the Public Health Service at Spartanburg, S. C.

PROFESSOR BENJ. L. MILLER, head of the department of geology of Lehigh University, has left for an extended trip through South and Central America in company with Dr. Joseph T. Singewald, Jr., associate in economic geology in Johns Hopkins University. Most of their time will be spent in the various mining districts of the countries visited, but they will make some other geologic investigations, especially in the Andes, where

they hope to study some of the highest volcanic peaks.

Dr. PHILIP J. CASTLEMAN, who has held the position of assistant director of the bacteriological laboratory of the Boston Board of Health, has been appointed director of the laboratory. He succeeds Dr. James J. Scanlan, whose death occurred recently.

COOPERATIVE agreements have been effected by the Oregon Agricultural College and the Drainage Division of the United States Department of Agriculture, whereby extensive drainage operations will be carried on in Oregon during the coming year. Mr. Guy N. Hart, of the federal department, and Professor W. L. Powers, irrigation and drainage specialist of the college, expect to begin operation about April 15.

Dr. ERNEST ANDERSON, professor of general and physical chemistry at the Massachusetts Agricultural College, has had under consideration the position as head of the department of science of the Margaret Morrison School of the Carnegie Institute, Pittsburgh, Pennsylvania, but has decided to remain in Massachusetts.

FRANKLIN C. GURLEY, a graduate assistant in chemistry at the Massachusetts Agricultural College, has accepted a position as chemist with the Benzol Products Company of Philadelphia.

The third annual Faculty Research Lecture at the University of California was given by Professor Armin O. Leuschner on March 23 on "Recent Progress in the Study of Motions of Bodies of the Solar System."

The annual meeting of the Syracuse University Chapter of the Alpha Omega Alpha Fraternity was held March 18. A banquet was served at which the guest of honor was Dr. Walter B. Cannon, of Harvard University, who delivered an address on "The Psychology of Martial Emotions."

At a general meeting of the New York Academy of Sciences and its affiliated societies on March 22 at the American Museum of Natural History there was a social hour, with refreshments, beginning at 9:30 P.M., preceded, at 8:15 P.M., by a lecture under the auspices

of the Section of Anthropology and Psychology, entitled, "Incidence of the Effect of Moderate Doses of Alcohol on the Nervous System," by Professor Raymond Dodge, of Wesleyan University.

Dr. AUGUSTUS H. GILL, professor of technical analysis at the Massachusetts Institute of Technology, addressed the Detroit Engineering Society on March 19 on "Lubricating Oils: Essentials and Characteristics."

Dr. GEORGE W. CRILE repeated his lecture on "Education and War" in the Amasa Stone Memorial Chapel, Western Reserve University, on the evening of March 31. Dr. Crile consented to repeat his lecture by reason of the great numbers who were unable to gain admission at its first delivery.

Mr. F. H. NEWELL, head of the United States Reclamation Service, addressed the students of the College of Engineering, University of Illinois, on March 24, on the subject of "The Engineering and Economic Results of Reclamation Work."

PROFESSOR CHAS. BASKERVILLE lectured before the Princeton Chemical Society on February 25, on "Physical Chemistry and Anesthesia."

PROFESSOR H. P. TALBOT, of the Massachusetts Institute of Technology, lectured on "The Noble Gases," on March 25, before the Phi Lambda Upsilon of Columbia University.

The fifth annual May lecture of the Institute of Metals, London, will be given on May 12 by Sir J. J. Thomson.

A SPECIAL lecture on the septic infection of wounds was delivered before the Royal Society of Medicine, London, on March 30, by Sir Almroth Wright, who dealt with the results of his investigations and research with the expeditionary force.

A STATE biological survey, suggested by the Ohio Academy of Science, is being undertaken with a state appropriation of \$2,500, a number of the colleges of the state cooperating. The preparation of duplicate material and separate collections for the colleges and other educational institutions is the primary feature of the work.

Dr. SIDNEY COUPLAND has been appointed Harveian orator of the Royal College of Physicians, London, for 1915; Dr. J. Michell Clarke Bradshaw lecturer for 1915, and Dr. Samson G. Moore Milroy lecturer for 1916.

LADY HUGGINS, widow of Sir William Huggins, the distinguished astronomer, and known for her scientific work, died at her home in London, on March 25. Lady Huggins was born in Dublin and married Sir William Huggins in 1875. She was joint author with him of many scientific papers, and of an Atlas of Representative Stellar Spectra. She was the author of a monograph on the Astrolabe; of articles in the *Encyclopædia Britannica*, and of papers in astronomical and archeological journals.

PROFESSOR NEUHAUSS, of Berlin, noted for his anthropologic investigations and his work in the field of color photography, has died at the age of fifty-nine years from diphtheria, contracted while engaged in military hospital work.

DR. CLON STÉPHANOS, director of the Anthropological Museum of the University of Athens, died on January 24, at the age of sixty years.

A CORRESPONDENT informs us that the following German zoologists have been killed in the war: Professor Stanislaus von Prowasek, head of the zoological department of the Institute for Tropic Diseases, Hamburg; Dr. W. Meyer, assistant in the same institute; Dr. W. Mulsow, assistant in the protozoological department of the Institute for Infectious Diseases, Berlin; Dr. G. Kantsch, docent for zoology, Kiel; Dr. v. Steudell, Edinger Institut, Frankfurt; Dr. v. Müller, assistant in the Zoological Institute, Kiel; Dr. v. Greinz, assistant in the Zoological Institute, Königsberg. The following have been wounded, but have in some cases recovered: Professor O. zur Strassen, professor of zoology, Frankfurt; Professor L. Rhumbler, professor of zoology, Forest School, Minden; Dr. W. Reichenperger, docent for zoology, Bonn; Dr. C. Thienemann, docent in Münster.

The American Ethnological Society has addressed the following reply to the French universities, which have addressed the scientific

bodies of neutral countries, setting forth their view of the causes of the war:

The American Ethnological Society acknowledges the receipt of the communication of the French universities to the universities of the neutral countries, dated November 3, 1914, and takes the opportunity to express its sincere sympathy for the sufferings that the present war is inflicting upon France and other European countries.

The society appreciates and respects the sentiments that have dictated the statement transmitted to it, but believes, regardless of the feelings of the individual members, that it behooves it to listen with the same respect that it gladly grants to you to the statements emanating from other nations. The society, being located in a neutral country, does not share the passions engendered by the patriotic feelings of the citizens of all the contending nations. It is conscious, however, that if the United States of America should find themselves involved in a similar struggle, our members might feel the same intense desire to convince the world of the righteousness of their cause as impels at present French, German and British scholars.

At present, on account of the remoteness from warlike passions, the society is mindful that the time will come (and we devoutly hope it may come soon) when the universities and scientists of the whole world may work together again for the true ideals of mankind, that know no national boundaries, when respect for the individuality of each nation may again take the place of harsh recrimination, when the true spirit of cooperation that has characterized scientific work of the past century may reappear. When that moment arrives, the passionate expressions of an excited time will not and must not stand in the way of mutual understanding and of a renewal of old friendships.

The council of the Society of American Bacteriologists has decided to hold a special summer meeting in San Francisco, August 3, 4 and 5, 1915. The chairman of the local committee of arrangements is Dr. Wilfred H. Manwaring, Stanford University, California.

The Princeton University Observatory has received from Mr. Archibald D. Russell, of New York, a gift of the sum necessary for the carrying on for five years of its share of the work described in Professor Pickering's summary of the present needs of astronomical research (*SCIENCE*, January 15, 1915).

THROUGH the efforts of Dr. Ralph Arnold, and other alumni of the department of geol-

ogy and mining, Stanford University has just added to its collections the working library and material of the late Professor Henry Hemphill, of Los Angeles. The collection contains between 8,000 and 9,000 specimens of shells and 150 volumes. The material is of very great importance in the study of the Tertiary geology of the Pacific coast, and especially of the geology of the petroleum deposits of California.

THE trustees of the Presbyterian Hospital, New York City, have taken an option to purchase the former American League baseball grounds, bounded by Broadway, Fort Washington avenue, 185th and 188th Streets. This site is owned by the New York Institute for the Education of the Blind, which has been holding it in the market at \$2,000,000. Purchase of the site is made possible by the bequests of the late John S. Kennedy, by whose will the hospital receives about \$2,500,000. It is understood that the College of Physicians and Surgeons, the medical school of Columbia University would be removed to the new site. Mr. Edward S. Harkness gave, in 1910, \$1,500,000 toward an alliance between the hospital and the university.

UNIVERSITY AND EDUCATIONAL NEWS

By the will of General Brayton Ives, of New York City, the largest part of his estate is bequeathed to Yale University for its general purposes. The daily papers estimate the value of the bequest at from \$750,000 to \$1,500,000.

MR. W. E. ALLEN, of Sheffield, has bequeathed about \$750,000 to public purposes, including \$25,000 and part of the residuary estate to the University of Sheffield for work in applied science.

ACCORDING to private information received from Mexico, the Carranza government has closed all educational and scientific institutions in Mexico, including not only the University, the Geological Institute, the Medical Institute and the National Museum, but also all normal schools, high schools and elementary schools under its control.

THE department of chemistry at Iowa State College, Ames, Iowa, is now installed in the

new chemistry building which replaces the one destroyed by fire in March, 1913. The building is constructed entirely of brick, stone and concrete and is as near fireproof as possible. The initial cost was \$200,000, and the building is 244 feet by 162 feet; three stories high, with a usable basement.

THREE Whiting fellowships in physics, each with an income of \$600, for the college year 1915-16, have been filled at the University of California. Fellowships on this endowment fund are conferred for the purpose of furthering advanced study, either abroad or at an American university.

STUDENTS in the newly established forestry school at the University of California are to receive instruction in game conservation. They will be taught to recognize at sight the different species of game fish and animals and will be informed as to the economic value of each and the means by which they can be conserved. Dr. H. C. Bryant, in charge of the bureau of education, publicity and research recently established by the California Fish and Game Commission, will give the introductory lectures. He will be followed by N. B. Scofield, in charge of the department of commercial fisheries, and Dr. W. P. Taylor, curator of mammals in the University of California Museum of Vertebrate Zoology.

DR. ANDREW HUNTER, of the Cornell Medical School, has been appointed professor of pathological chemistry in the University of Toronto.

DR. R. TRAVERS SMITH has been appointed to the chair of materia medica, therapeutics and pharmacology in the school of surgery of the Royal College of Surgeons in Ireland.

DISCUSSION AND CORRESPONDENCE

EVIDENCE BEARING ON THE ORIGIN OF HUMAN TWINS FROM A SINGLE OVUM

ON the supposition that twins originate always from two ova, and that the chances are even as to whether an individual of a pair of twins is to be male or female, the ratio of like pairs to those whose members are of different sex may be worked out according to the laws of chance. The Mendelian ratio

under corresponding circumstances is 1:2:1; that is, there should be one pair of boys, to two mixed pairs, to one pair of girls. In other words, if the members of a pair of twins always developed from separate ova, we should expect to find twice as many pairs whose members differ in sex, as there are pairs of girls, or pairs of boys. I have been able to think of no factor which may reasonably be supposed to be acting in a constant direction to alter this ratio.

I have undertaken to compare with this hypothetical ratio the ratio found among births of twins in this country. My data number 3,334 twin births which occurred in the states of Connecticut, Maine and Vermont during the years 1899 to 1912. Of this number 1,118 are pairs of boys, 1,193 are boy and girl, and 1,023 are pairs of girls. This is almost a 1:1:1 ratio, showing the effect, however, of the predominance of male births. There is obviously a large excess of pairs similar in sex over what is to be expected on the supposition that twins originate in all cases from separate ova, an excess of more than 500 pairs of boys, and almost 500 pairs of girls.

This seems to point towards the conclusion that twins may originate from a single fertilized ovum. In the light of present knowledge this certainly is a possible explanation of the statistics. If the figures given will bear this interpretation, we may say that less than half (44.3 per cent.) of the twin births of similar sex, or less than one third (28.4 per cent.) of all twins, originate from one ovum, while slightly more than half (55.7 per cent.) of those of similar sex have developed simultaneously from two separate ova.

MARGARET V. COBB

FALLS CHURCH, VA.

NATURALIST'S DIRECTORY

TO THE EDITOR OF SCIENCE: As you have given liberal space to criticize the book, you will doubtless be willing to give space in which I can explain the matter.

In the first place, this book has not been issued for some eight years, and in getting out

the new edition I decided that not a single name would be included unless I had a request that the name should be included from each party. If you find that there are a good many naturalists omitted from the directory, it was because they were too busy, or more likely too careless of such matters to take time to return the blanks which I sent them. Every naturalist of any consequence, and a great many collectors, received three notices each and none of the names were included in the book unless they replied.

Since getting out the work some of these noted scientists have taken time to write three or four criticisms of the book, while they would not take time before publication to even sign their names to the blanks I sent them. There are a few typographical errors in the book as there are bound to be in any work of this kind, and the transposition of two or three entries, to which you have taken great pains to call attention, was caused by the misplacement of one or two linotype slugs.

It is my intention to get out another edition of the Naturalist's Directory in a year from now, and I hope naturalists, generally, will be as free with their assistance in bringing the new edition up to date, as they have been in criticizing the edition just published.

S. E. CASSINO

SALM, MASS.

SCIENTIFIC BOOKS

Die Variation im achtzehnten Jahrhundert. Ein historischer Beitrag zur Immunitätsforschung. By ARNOLD C. KLEBS. Giessen, A. Töpelmann. 1914. 8vo. Pp. 78.

Few physicians know that throughout the entire eighteenth century, and before Jenner's time, there was a vast wave of experimental research in the problem of preventive inoculation against disease, now almost forgotten. Starting in 1713, it passed into a period of twenty years' stagnation about 1727, with a revival in 1746 and a truly scientific phase during 1764-68. When a bibliography of some 800 titles, by the author of the above monograph, was shown to a highly educated physi-

cian, he said: "Yes, but all that is merely a fragment of the huge literature of vaccination!" not realizing that variolation and vaccination are distinct and separate episodes in medical history. Variolation is preventive inoculation against smallpox by means of virus taken from the human subject. In vaccination, the virus is supposed to be modified or attenuated by transmission through the body of the cow. The recent application of such terms as "vaccines" or "vaccinotherapy" to diseases other than smallpox, although now likely to remain current, is inexact and unscientific, since none of the non-Jennerian "vaccines" are passed through the cow.

Dr. Klebs, who has gone into this subject more extensively than any one else, has, in his memoir, amplified the admirable paper, read at the Johns Hopkins Hospital in 1912, by an examination of literature covering over 1,200 titles.¹ Only von Pirquet has appreciated the importance of this vast literature, which he has declared to be too overwhelming and distracting for investigation. The object of Klebs's memoir is to show the importance of "historical medicine" in the illumination or interpretation of present-day problems. For instance, the extensive experiments in inoculation of smallpox which Councilman, Brinkerhoff and Tyzzer made upon anthropoid apes at Manila, did not throw any such light upon the subject as the thousands of successful inoculations made upon man in the eighteenth century. Dr. Klebs regards variolation as a remarkable example of the value of folk intuitions in etiology and therapy. Many important advances in practical medicine have undoubtedly come from the non-medical, but these can hardly be said to have arisen from the great mass of the people, rather, on the primitive minds, *adscripti glebae*, whose mental development was a little higher than the average. The usual process in evolution is that out of a vast number of people of primitive minds, *adscriptus glebae*, whose

mental processes are nearly all exactly alike, there arises occasionally one in whom a more specialized type of mind is born, through suffering or other experience. Then, as Emerson says, "all things are at stake." The interesting thing about variolation is that, like the primitive chipped flints all over the globe, or the ever-recurring *themata* of folk-lore, it seems to have arisen spontaneously among different savage or semi-civilized races. In this monograph it is shown that variolation has been practised from a remote period in China and India and among such African tribes as the Somalis, Ashantis and Wagandas. Cotton Mather is said to have first heard of the practise from his African slave, Onesimus. Baas's statement that inoculation is mentioned in the Atharva Veda is, however, unverifiable. In Germany and Russia, the custom of "buying the smallpox" was known from the seventeenth century on, variolation being produced by bringing the scabs, purchased in open market, or the pus in contact with the skin. This was probably a phase of the ancient superstition of the sympathetic transference of disease. In 1713, smallpox inoculation was brought to European attention from Oriental sources by Emanuel Timoni, who had his daughter inoculated in 1717. Lady Mary Montagu followed with the inoculation of her infant daughter in April, 1721, and, on June 26, 1721, Zabdiel Boylston of Boston, Mass., began his long series of inoculations in which, by 1752, he had 2,124 cases, with only 80 deaths, while, in 1743, Kirkpatrick, in South Carolina, had nearly 1,000 cases, with 8 deaths. At this time the *modus operandi* was incision, with sometimes a dietetic and depletory "preparation," usually blood-letting and purging. In 1780, Robert and Daniel Sutton were inoculating by puncture, discarding the depletory regimen for the more sensible strengthening of the patient by dietetic and hygienic means, and had some 30,000 cases, with about 4 per cent. mortality. Attenuation of the virus was attempted by passing it through several human subjects (Kirkpatrick's arm-to-arm method), by using very small quantities, by dilution with water, calomel, etc., or by choosing the virus at the crude or unripe stage. The author

¹ A remarkably complete bibliography of variolation, down to Jenner's time, and of vaccination (1798-1861) was printed (not published) by Dr. Ludwig Pfeiffer (of "Pestilentialia in nummis") about 1868.

cites experiments which would stand comparison with those carried out in modern laboratories, especially those tabulated from William Watson's series of 1768, in which it is seen that Jenner did not initiate experimental research upon the subject but rather devised or followed lines already established before him. The most scientific worker in the field was Angelo Gatti of Pisa, who obtained permission to inoculate in Paris by the rational method of puncture and preparation in 1769. Gatti maintained that smallpox is always caused by the introduction into the body of a foreign body, which is in the nature of a specific virus in that it reproduces itself and multiplies, the disease being communicated by contact, inhalation or ingestion. He waxed furious against the senseless practise of weakening the patient by bleeding and purging, adopted Sutton's open-air and hydropathic régime, and offered prizes in real money for any authenticated case of reinfection after inoculation. Such cases he regarded as eruptions from a mixed infection of other exanthems, such as scarlatina or measles, which he also thought capable of transference by inoculation. The main difficulty with variolation was that each inoculated person was a possible "carrier" of the disease, and this occasioned Gatti and his associates considerable trouble in Paris. In the meantime, Tronchin, Tissot, Mead and other eminent physicians were influential in spreading the practise, which became a common preventive measure in America during the Revolutionary War. In 1768, Thomas Dimsdale was invited to St. Petersburg to inoculate Catherine the Great and her son, receiving for his trouble a barony, \$50,000 down, an annuity of \$2,500, \$10,000 for his expenses and handsome gifts of diamonds and furs. Jenner's experiments of 1796-8 soon swept variolation from the field, for the sufficient reason that there was little mortality and no possibility of transference of the disease by the vaccinated person. Variolation was declared a felony by Act of Parliament in 1840.

Dr. Klebs's memoir is well worthy of perusal by all who are interested in the history of preventive inoculation. Its permanent value is that it obviates the boresome necessity of

investigating the huge literature of variolation, covering even the secular memoirs of eighteenth century celebrities. Its engaging style makes it eminently readable, revealing everywhere the spirit of its genial author.

F. H. GARRISON

ARMY MEDICAL MUSEUM

A Primer on Alternating Currents. By W. G. RHODES. Longmans, Green & Company. 1912. Pp. 145.

Although this book, according to the author, is primarily intended for students preparing for the alternating current part of the ordinary grade examination in electrical engineering of the city and guilds of London, it should be useful to those desiring a very brief elementary course on alternating currents and alternating current machinery. The book is primarily adapted to the use of evening classes in technical schools, and is written in such a way that no knowledge of mathematics is required beyond the elements of algebra. In order to avoid the necessity for the students in these classes to possess a multiplicity of books, such simple mathematical relations as are necessary for the development of the subject are proved in the first chapter of the book. For a similar reason, some useful constants and a short table of logarithms are given.

The early chapters of the book are devoted to developing the elementary principles of magnetism, induction and alternating currents. Alternating currents in circuits containing inductance and capacity are briefly considered. The rest of the book deals with transformers, synchronous motors, induction motors and rotary converters. In this part of the book use is made of simple vector diagrams. At the end of the book a few pages are given to the elementary principles underlying transmission of electrical energy and to simple power measurements. The usefulness of the book is increased by the addition of a number of examples with answers which are given at the end of each chapter.

This little book is well adapted for the purpose for which it is intended. One should expect to find in its 145 pages more than a most brief and elementary treatment of the

broad subject of alternating current and alternating current machinery.

RALPH R. LAWRENCE

Alternating Current Machinery. By BARR and ARCHIBALD. The Macmillan Company. 496 pages and 16 plates.

The title of this book is too broad and somewhat misleading as only certain types of alternating current machinery are considered, namely: the transformer, the alternator, and the rotary converter. No mention is made of induction machines or of the synchronous motor. The first chapters are devoted to complex wave forms and their analysis and to the properties of insulating materials used in alternating current machinery. The insulation of transformers and generators is also briefly considered. The remaining chapters deal with the theory and the design of the transformer, the alternator and the rotary converter. Three chapters are devoted to the transformer. Two of these are given up to the consideration of the fundamental principles, construction and vector diagrams, while the third is confined entirely to design. Some examples of different designs are included. Nine of the remaining twelve chapters deal with the alternator. The mechanical construction of alternators, different types of armature windings, harmonics caused by teeth, and the magnetic circuit are discussed in the first of these chapters. Several chapters are devoted to the discussion of armature reaction, voltage regulation and regulation tests. The effect of a sudden short circuit is also considered. The discussion of the losses, efficiency and heating of alternators is also given considerable space. One chapter is devoted to the parallel operation of alternators. The last chapter on alternators, a chapter of about forty pages, deals only with design. Several examples of design are given. The remaining three chapters are confined to the rotary converter and take up the transformation voltage ratio, armature reaction, armature heating and output. Voltage regulation, losses and efficiency, methods of starting and parallel working are discussed. The last chapter of the book deals entirely with the design of converters, and as in the other

chapters on design, examples of the design of several converters are given. It is unfortunate that the author has used clockwise and anticlockwise directions of rotation indiscriminately on the vector diagrams to indicate a positive direction of rotation. Although an arrow is added to each vector diagram to indicate which direction of rotation has been adopted, the lack of a definite convention in this connection is apt to lead to confusion. The book is in general well arranged and should be a valuable one alike to the student and the engineer.

RALPH R. LAWRENCE

SCIENTIFIC JOURNALS AND ARTICLES

THE opening (January) number of volume 16 of the *Transactions of the American Mathematical Society* contains the following papers:

G. M. Green: "On the theory of curved surfaces, and canonical systems in projective differential geometry."

H. S. White: "The multitude of triad systems on 31 letters."

G. A. Miller: "The ϕ -subgroup of a group."

R. L. Moore: "On a set of postulates which suffice to define a number-plane."

W. C. Graustein: "The equivalence of complex points, planes, lines with respect to real motions and certain other groups of real transformations."

J. E. Rowe: "Invariants of the rational plane quintic curve and of any rational curve of odd order."

M. G. Gaba: "A set of postulates for general projective geometry."

Virgil Snyder and F. R. Sharpe: "Certain quartic surfaces belonging to infinite discontinuous cremonian groups."

Joseph Slepian: "The functions of a complex variable defined by an ordinary differential equation of the first order and the first degree."

Arthur Ranum: "On the differential geometry of ruled surfaces in 4-space and cyclic surfaces in 3-space."

THE February number (Vol. 21, No. 5) of the *Bulletin of the American Mathematical Society* contains: Report of the eighth regular meeting of the Southwestern section, by O.

D. Kellogg; "Note on the potential and the antipotential group of a given group," by G. A. Miller; "The equation of Picard-Fuchs for an algebraic surface with arbitrary singularities," by S. Lefschetz; Review of Manning's *Geometry of Four Dimensions*, by J. L. Coolidge; "Shorter Notices"; Schröder's *Entwicklung des mathematischen Unterrichts an den höheren Mädchenschulen Deutschlands*, by E. B. Cowley; de Montessus and d'Adhémar's *Calcul numérique* and Dickson's *Elementary Theory of Equations*, by R. D. Carmichael; Smith's *Teaching of Geometry* and Smith and Mikami's *History of Japanese Mathematics*, by J. V. McKelvey; Study's *Die realistische Weltansicht und die Lehre vom Raume und Jordan and Fiedler's Contribution à l'Etude des Courbes convexes fermées et de certaines Courbes qui s'y rattachent*, by Arnold Emch; Mrs. Gifford's *Natural Sines to Every Second of Arc, and Eight Places of Decimals*, by D. E. Smith; Cobb's *Applied Mathematics*, by E. B. Lytle; von Sanden's *Praktische Analysis* and Hjelmslev's *Darstellende Geometrie*, by Virgil Snyder; "Notes"; and "New Publications."

THE March number of the *Bulletin* contains: Report of the twenty-first annual meeting of the society, by F. N. Cole; Report of the winter meeting of the society at Chicago, by H. E. Slaughter; "The structure of the ether," by Harry Bateman; "Shorter Notices"; Killing and Hovestadt's *Handbuch des mathematischen Unterrichts*, Band II, by D. D. Leib; Cahen's *Théorie des Nombres*, Tome premier, and Darboux's *Théorie générale des Surfaces*, première Partie, by T. H. Gronwall; "Notes"; and "New Publications."

SPECIAL ARTICLES

INTERPOLATION AS A MEANS OF APPROXIMATION TO THE GAMMA FUNCTION FOR HIGH VALUES OF n ¹

VARIOUS approximations to the value of $\Gamma(n)$ when n is large have been suggested by different workers and are in every-day use. In

actual statistical practise the one which has appealed to the writer as most satisfactory, having regard to ease of calculation and degree of accuracy of result, is that of Forsyth,² which is

$$\Gamma(n+1) = \sqrt{2\pi} \left(\frac{\sqrt{n^2 + n + \frac{1}{2}}}{e} \right)^{n+\frac{1}{2}}$$

This is in error (in defect) in the proportion of $1/240n^2$.

It lately occurred to me that possibly a further saving of labor in computation, without loss of accuracy, could be made by interpolating in a table of $\log n$ to get $\log \Gamma(n)$. Tables of the sums of the logarithms of the natural numbers have recently been made readily available to statistical workers from different sources.³ Such tables all proceed, of course, by integral steps of the argument n .

The question then is to determine what the order of magnitude of the error will be if one interpolates from such a table proceeding by integral steps, in order to determine $\Gamma(n)$. The relation

$$\Gamma(n+1) = \frac{n!}{1} \quad (1)$$

is exact when n is an integer. How great is the inequality when n is not integral but fairly large?

To test this matter I asked Mr. John Rice Miner, the staff computer of the laboratory, to carry through the computations for a short series of representative values of n . This he has done, with the results set forth in Table I, for which I am greatly obliged. It should be said that in all the computations seven-place logarithms only have been used. The first column, headed "exact value," gives the result obtained by using the value of $\log \Gamma(x)$ for $x = 1.123$ from Legendre's tables, and then summing the logarithms up to $n-1$ for each desired value. This is the usual process, depending on the relation

¹ Forsyth, Brit. Assoc. Rept. for 1883, p. 47.

² Cf. Pearl and McPheters, *Amer. Nat.*, Vol. XLV., 1911, p. 756. More recently a longer table of sums of logarithms has been published in Pearson's "Tables for Statisticians and Biometrists," Cambridge, 1914.

³ Papers from the Biological Laboratory of the Maine Agricultural Experiment Station, No. 80.

$$\Gamma(n+1) = n\Gamma(n) = n(n-1)(n-2) \dots (n-r)\Gamma(n-r). \quad (\text{ii})$$

It becomes an exceedingly tedious operation when n has a value of over, say, 20. In calling this the "exact" value in the table the intention is merely to convey the idea that the only approximation involved is that incident upon the use of 7-place logarithms, the process *per se* being an exact one. The fourth and fifth columns of the table give the results obtained by using the values of $\log |n|$, their first second and third differences, in the usual advancing difference interpolation formula

$$u_{x+n} = u_x + n\Delta u_x + \frac{n(n-1)}{2}\Delta^2 u_x + \frac{n(n-1)(n-2)}{6}\Delta^3 u_x \dots \quad (\text{iii})$$

TABLE I
Values of $\log \Gamma(n)$ by Different Methods

n	Exact Value	Forsyth's Approximation	Interpolation Using Δ^3	Interpolation Using Δ^5
5.125	1.4613860	1.46138679	1.4619188	1.4615009
15.125	11.0834931	11.0834916	11.0835559	11.0834865
35.125	23.9574108	23.9574096	23.9575731	23.9574119
55.125	38.6594135	38.6594136	38.6594251	38.6594138
75.125	107.7498704	107.7498692	107.7498727	107.7498720

From this table it is evident that the interpolation method, when third differences are used, gives values slightly better than those by Forsyth's method when $n \leq 25$. For $n = 75$ or more the interpolation method using only second differences gives an approximation sufficiently close for all practical statistical purposes. As to the labor involved, there is no great amount of choice between Forsyth's and the interpolation method, but on the whole there appears to be a distinct, if small, advantage in favor of the interpolation.

RAYMOND PEARL

THE GEOLOGICAL SOCIETY OF AMERICA

THE twenty-seventh annual meeting of the Geological Society of America was held at the Academy of Natural Sciences, Philadelphia, December 29-31, 1914, under the presidency of Dr. George F. Becker, of the United States Geological Survey, Washington, D. C. On account of Dr. Becker's

enforced absence through illness, the sessions were presided over by Vice-presidents Waldemar Lindgren and Horace B. Patton. In attendance there were registered 117 Fellows of the Society and the number of students and others, including members of the American Association for the Advancement of Science who were present at the sessions, swelled the attendance to more than 200, making this one of the most largely attended meetings in the history of the society.

At the first general session of the society Dr. Samuel G. Dixon, president of the Academy of Natural Sciences, welcomed the visiting geologists and paleontologists, making them feel very much at home as the guests of the historic academy.

The report of the council, as submitted in print, showed that the present enrollment of the society is 363, aside from the 19 new fellows elected at the meeting but who had not yet qualified. During the year 1914 the society lost five fellows by death: Alfred E. Barlow, Albert S. Bickmore, Horace C. Hovey, A. B. Wilmott and Newton H. Winchell; and three correspondents: H. Rosenbusch, Eduard Suess and Th. Tschernyschew. The treasurer's report showed that the society was in a flourishing condition financially and the editor's report indicated an unusual activity in publication during the past year.

The papers presented in the three general sessions of the society were as follows:

Relation of Bacteria to Deposition of Calcium Carbonate: KARL F. KELLEMAN.

At the suggestion of Dr. T. Wayland Vaughan, bacterial studies of water and bottom mud from the Great Salt Lake, and sea water and bottom deposits from the vicinity of Florida and the Bahamas were undertaken in the hope of supplementing the work of Vaughan,¹ of Drew² and of Dole³ in regard to the probable agencies concerned in the precipitation of calcium carbonate and the formation of oolites.

It has been possible to form calcium carbonate by the action of bacteria on various soluble salts of calcium both in natural waters and in synthetic mixtures. The most important natural precipita-

¹ T. Wayland Vaughan, *Bull. Geol. Soc. Am.*, Vol. 25, No. 1, p. 59, March, 1914. Also Publication No. 182, Carnegie Inst. of Washington, pp. 49-67.

² G. H. Drew, Publication No. 182, Carnegie Inst. of Washington, pp. 49-67.

³ R. B. Dole, Publication No. 182, Carnegie Inst. of Washington, pp. 69-78.

tion is probably the transformation of calcium carbonate by the combined action of ammonia, produced by bacteria either by the denitrification of nitrates or by the fermentation of protein, together with carbon dioxide, produced either by the respiration of large organisms or the fermentation of carbohydrates by bacteria. Both ordinary crystals of calcium carbonate and oolites may be produced by the growth of mixed cultures of bacteria, either in salt or fresh water. The zonal structure of the oolites of bacterial origin and of those found in nature in oolitic deposits appears to be exactly the same; undoubtedly this shows the similarity of the processes of their origin.

Coral Reefs and Reef Corals of the Southeastern United States, Their Geologic History and Their Significance. THOMAS WAYLAND VAUGHAN.

After briefly alluding to some of the more recent publications on coral reefs, the author stated what in his opinion were the necessary lines of investigation in order to understand the ecologic factors influencing coral reef development, the constructional rôle of corals and other agents, and the series of geologic events which preceded any particular coral reef development. The geologic history of the extensive coral reefs of the southeastern United States and nearby West Indian islands, which have been the subject of investigation for a number of years, was outlined and the bearing they have on the theory of coral reef formation was indicated.

The author stated his conclusions regarding the Florida coral reefs as follows: (1) Corals have played a subordinate part, usually a negligible part, in the building of the Floridian plateau; (2) every conspicuous development of coral reefs or reef corals took place during subsidence; (3) in every instance the coral reefs or reef corals have developed on platform basements which owe their origin to geologic agencies other than those dependent on the presence of corals.

The older Tertiary reefs and reef corals of St. Bartholomew, Antigua and Anguilla all grew on subsiding basements. The relatively small proportion of the contribution by corals to calcareous sediments in Florida, the Bahamas and the West Indies was shown.

It was shown that the Floridian plateau was similar in configuration to the Mosquito Bank off Nicaragua, to Campeche Bank off Yucatan and to Georges Bank off Massachusetts; the east side of the Floridian plateau is similar to the continental shelf off Cape Hatteras. The platform which supports the reef along the east coast of Florida ex-

tends beyond the reef limits northward of Fowey Rock. The reef platform of the Great Barrier Reef of Australia is similar to the continental shelf of eastern North and Central America, and it continues south of the reef limits. Rosalind Bank, Caribbean Sea, was compared with Rangiroa, Paumotu, which is similar in essential features. The complex history of the coral reef foundations in Florida, Antigua, St. Martin, Anguilla and Bermuda was described, and it was stated that the formation of the platforms could not be referred solely to Pleistocene time.

Attention was directed to the facts that around the Island of Saba, in which volcanic activity has so recently ceased that the crater is still preserved, there was scarcely any platform at all; that in the case of the young but slightly older volcanic island of St. Kitts, the platform was narrow, while the geologically much older islands standing above the Antigua-Barbuda bank, the St. Martin plateau, and the Virgin Bank, rise above platforms which are miles across and have an area many times greater than that of the present land surfaces. Width of platform is therefore indicative not of the amount of submergence, but of the stages attained by platform processes.

The conclusions were summarized as follows:

1. Critical investigations of corals as constructional geologic agents are bringing constantly increasing proof that they are not so important as was long believed, and that many of the phenomena formerly attributed to them must be accounted for by other agencies. Here it should be emphasized that the ecology of probably no other group of marine organisms is known nearly so thoroughly as that of corals.

2. All known modern off-shore reefs which have been investigated grow on platforms which have been submerged in recent geologic time.

3. No evidence has as yet been presented to show that any barrier reef began to form as a fringing reef on a sloping shore and was converted into a barrier by subsidence; but it is clear that many, if not all barrier reefs stand on marginal platforms which already existed previous to recent submergence and the formation of the modern reefs.

4. Study of the geologic history of coral reef platforms has established that there were platforms in early Tertiary time on the site of many of the present-day platforms, and evidence has not as yet been adduced to prove long-continued, uninterrupted subsidence in any coral reef area. There have been many oscillations of sea level and recent submergence is probably complicated in many

areas by differential crustal movement concomitant with increase in volume of oceanic water through deglaciation.

5. The width of a submerged platform bordering a land area is indicative not of the amount of submergence, but of the stage attained by planation processes. Other conditions being similar, the longer the period of activity of such processes the wider will be the platform.

6. The principal value of the coral reef investigation to geology consists not so much in what has been found out about corals as in the study of a complex of geologic phenomena, among which coral reefs are only a conspicuous incident.

Causes Producing Scratched, Impressed, Fractured and Recemented Pebbles in Ancient Conglomerates: JOHN M. CLARKE.

The Devonian conglomerate lying beneath the fish-beds of Mignonasba, P. Q., is a characteristic "Nagelfluh" filled with scratched, fractured and deeply impressed pebbles. Specimens exhibited indicate that the explanation of the phenomena of impression by solution, as suggested by Sorby, Haim, Kayser and others, is inadequate and that the effects described are in large part actually due to forcible contact resulting from internal friction. Some of the pebbles show unqualified evidence of glacial scratching and the entire mass is regarded as an outwash from glacial moraine.

Revision of Pre-Cambrian Classification in Ontario: WILLET G. MILLER AND CYRIL W. KNIGHT.

During the past decade the authors have been engaged in detailed work on pre-Cambrian areas in various parts of the Province of Ontario. The results of this work, and that of other investigators, have made apparent the necessity for revising the age classification of the pre-Cambrian rocks, particularly in the use of the terms Huronian, Laurentian and others. The following classification and nomenclature have therefore been adopted by the Ontario Bureau of Mines.

KEEWATIN.

Unconformity.

ANIMIKIAN.

Under this heading the authors place not only the rocks that have heretofore been called Animikie, but the so-called Huronian rocks of the "classic" Lake Huron area, and the Cobalt and Ramsey Lake series. Minor unconformities occur within the Animikian.

Great Unconformity.
(ALGOMAN GRANITE AND GNEISS.)

Laurentian of some authors, and the Lorrain granite of Cobalt, and the Killarney granite of Lake Huron, etc.

Igneous Contact.

TIMISKAMIAN.

In this group the authors place sedimentary rocks of various localities that heretofore have been called Huronian, and the Sudbury series of Coleman.

Great Unconformity.

There is no evidence that this unconformity is of lesser magnitude than that beneath the Animikian.

(LAURENTIAN GRANITE AND GNEISS.)

Igneous Contact.

LOGANIAN.

Grenville (*Sedimentary*), Keewatin (*Igneous*).

The authors have found the Keewatin to occur in considerable volume in S. E. Ontario and have determined the relations of the Grenville to it.

Investigations by the junior author during 1914 have shown that certain rocks of the "classic" Huronian area of Lake Huron, the "Thessalon greenstones," that heretofore have been placed with the Keewatin, are of much later age, being in intrusive contact with the Animikian, as defined in the above table.

North American Continent in Upper Devonian Time:

AMADEUS W. GRAEUB.

The history of North America in the Upper Devonian has been worked out in some detail, on the basis of physical stratigraphy combined with paleontology.

At the opening of the Upper Devonian, marine waters were much restricted in North America, the greater part of the United States being exposed to active erosion of the previously deposited Hamilton or earlier formations, as indicated by disconformities. The Tully-Genesee sea was restricted to central New York, but extended northward over Canada. Appalachia, Atlantica (the Old Red Continent) and Mississippi were the chief continents. The evidence pointing to the gradual southward transgression of the sea over the eroded lands is clear. Three open marine water bodies existed throughout Upper Devonian time, each with its Urals, (2) the western or North Pacific, extending from central New York across Ellesmere land to the Urals, (2) the western or North Pacific extending across part of Alaska, (3) the eastern or Atlantic. The latter entered the interior by way of a narrow strait between Appalachia and Atlantica, permitting the periodic invasion of the Atlantic or Tropicoleptus fauna. There may have been a fourth South Pacific water body extending into Nevada, but this is less certain. Three principal river systems are recognized in the lowland of Mississippi. These have furnished the black mud for the black shales which were deposited in embayments of di-

minished salinity. The eastern or Genesee beds are restricted to New York and the states just south. The base of the black shale of Ohio, Michigan and Canada is younger than Genesee, as shown by stratigraphic and paleontologic evidence. The great fish fauna of these shales is shown by its occurrence and distribution to be primarily the fauna of these sluggish rivers projected at intervals into the brackish water of the embayments. The land flora of Mississippi is also preserved in these shales. The rivers of Appalachia and Atlantica also had their fish fauna, but these were of different types, their smaller size adapting them to these torrential streams. With them occurred the survivors of the Eurypterids, which also inhabited the rivers of the Paleozoic lands. The flora of Appalachia and Atlantica is likewise largely distinct from that of Mississippi. The deposits made by these rivers were partly preserved as sandy deltas and alluvial fans.

Present Condition of the Volcanoes of Southern Italy: H. S. WASHINGTON and A. L. DAY.

A brief description of the general condition and state of activity at Vesuvius, Etna, Vulcano and Stromboli, as observed during the summer of 1914.

Recent Eruptions of Lassen Peak, California: J. S. DILLER.

Lassen Peak, in northeastern California, at the southern end of the Cascade Range, has long been considered an extinct volcano, but has recently shown signs of rejuvenescence. The first of the recent outbreaks occurred at 5 P.M., May 30, 1914, and since then many eruptions have occurred. The nature of this remarkable phenomenon was illustrated and discussed.

Physiographic Study of the Cretaceous-Eocene Period in the Rocky Mountain Front and Great Plain Provinces: GEORGE H. ASHLEY.

The study of the rocks, especially of the coal beds, the structure and the life in the provinces named, appears to indicate that Upper Cretaceous

time in that region was occupied by a single movement of subsidence, somewhat irregular, but, on the whole, persistent: that this was followed by a period of general and differential uplift, to be followed in turn by renewed subsidence, interrupted locally, from time to time, by pronounced movements of differential uplift. Comparison is made between this interpretation and the assumed conditions in the eastern United States and certain deductions drawn as to the point in the time scale at which the first general uplift occurred.

Relation of Physiographic Changes to Ore Alterations: WALLACE W. ATWOOD.

While a land mass is being dissected, the groundwater table is slowly lowered through that mass, until, at the peneplain and base-level stages, the groundwater table remains almost stationary for long periods of time. During successive cycles of erosion the position of the base-level of erosion in the land mass being dissected must change, and, if climatic conditions remain constant, such changes are necessarily accompanied by changes in the position of the groundwater table. If the land mass is elevated, the base-level will be lowered through the land, and the groundwater table will be slowly lowered. When a land mass is depressed, the base-level of erosion and the groundwater table are elevated throughout that land mass. Moist climates will raise the groundwater table, and dry periods lower that table. As the groundwater table is raised or lowered, the zones in which the chemical changes associated with the secondary alteration of ore deposits take place are varied in thickness.

These facts indicate that physiographic studies may be profitably applied in the study of ore alterations, and conversely that the record of ore alterations may furnish important data bearing upon the physiographic evolution of the districts concerned.

The study of secondary ores by various investigators has called for intensive physiographic studies. During the past season field work was done in the vicinity of Butte, Montana, and Bingham Canyon, Utah, to determine the relationship of physiographic evolution to the secondary enrichment of ores in those regions. In this paper the problem of the application of physiography to the investigation of secondary ores was defined, and some of the results of the past season's field work were presented.

Graphic Projection of Pleistocene Climatic Oscillations: CHESTER A. REEDS.

Penck's survey, page 1168, "Die Alpen im Eiszeitalter," 1909, expresses graphically the climatic oscillations of the alpine district for Pleistocene and post-Pleistocene time. The key to the four glaciations and the three interglacial stages indicated in the curve was found in the four outwash deposits of glacio-fluvial streams on the northern foreland of the Alps in the vicinity of Ulm and Munich. Along the present stream valleys the glacio-fluvial deposits are arranged in terraces, the oldest occupying the highest position and the youngest, the lowest level. When the key was carried in mind to the French and Italian Alps the remarkable association of these deposits on the northern foreland was found to be applicable throughout. Hence the names of four small tributaries of the Danube which cross the outwash deposits on the Bavarian plateau, Günz, Mindel, Riss and Würm, were applied by Penck and Brückner to the first, second, third and fourth glaciations. The deposits of the third or Riss glaciation in the Swiss and French Jura extend farther out on the foreland than the deposits of the other glacial advances, but in other districts the morainal deposits of the second or Mindel stage extend beyond that of any other, hence it is regarded as the most extensive of the four alpine glaciations. The morainal and outwash deposits of the first or Günz glaciation are least in evidence while those of the fourth or Würm glaciation, the last, are most in evidence.

That the temperature of the alpine region was considerably colder during the stages of glaciation than during the interglacial stages and the present which is at the close of the retreating hemicycle of the last glaciation, is shown conclusively by the depressed snow lines. Penck has determined their position in the Alps for all four glaciations. They have a distribution parallel to that of the present snow-line, but occupying lower levels, namely, Günz, 1,800 meters, Mindel, 1,350 meters, Riss, 1,300 meters, and Würm, 1,200 meters below the present snow-line. During the interglacial stages the snow-line was approximately 300 meters higher than the present one. From the Höttinger Breccia near Innsbruck Penck determined that there was a temperature variation of 1° C. for every 200-meter change in the altitude of the snow-line.

The unit of measurement which Penck used in estimating the duration of the Pleistocene period is the retreating hemicycle of glaciation of the fourth or Würm stage, better known as the post-glacial period. In the alpine district Penck and

Brückner found that in this retreating hemicycle there were three minor advances called the Bühl, Gschnitz and Daun stadia. These advances were preceded by a prominent minor retreat of the Achen oscillation. From the lignite deposits of Dürnten, the deposits of the Mouta deltas and the turf deposits in many of the glacial swamps it has been possible to estimate the duration of this hemicycle of glaciation in years, as follows:

Subdivisions of Post-Glacial Time

	Years
Achen oscillation	9,000
Bühl advance and retreat	5,000
Gschnitz advance and retreat	4,000
Daun advance and retreat	3,000
Age of copper	1,000
Post-copper time	3,000
Total	25,000

The estimate on the duration of post-glacial time in America is based chiefly on the recession of the waterfalls of Niagara and St. Anthony. Recently Coleman* made an estimate based on the rate of wave erosion on the shore of Lake Ontario and glacial Lake Iroquois. Twenty-five thousand years is a figure which falls within the estimates made by Coleman, Taylor, Lyell, Chamberlain and Salisbury. It is a bit under those of Fairchild, Sardeson and Spencer and above those of Gilbert and Upham. It is considered a conservative figure.

Penck states that it must have been 16,000 to 24,000 years from the Buhl stadium to the present, with 20,000 years as an average, and 25,000 to 40,000 years from the beginning of the Achen retreat to the present. In selecting a figure, however, which shall be used as a unit of measurement in calculating the duration of the entire Pleistocene period, he chooses 20,000 years as the length of post-Würm time.

The correlation of the mountain glaciations of the Alps with those of the Scandinavian continental ice fields of Pleistocene time has not been worked out in all regions, but there is sufficient information at hand to say that there were four advances of the continental ice over northern Europe which correspond to the periods of ice advance upon the alpine forelands. Geikie remapped in 1914 the second, third and fourth glaciation distribution in Europe. G. de Geer delimited the retreating stages of the fourth glaciation in the Scandinavian peninsula in 1912.

A correlation of American with European glacial deposits has been made by Leverett. By consid-

* Coleman, A. P., Proceedings, Twelfth Inter. Geol. Cong., Canada, 1913.

ering with Leverett's the so-called Iowan glaciation contemporaneous with the Illinoian it is possible to correlate the Günz glaciation with the Nebraskan, the Kansan with the Mindel, the Illinoian with the Riss and the Wisconsin, early and late, with the Würm. There are corresponding interglacial stages. With the time units of Chamberlain and Salisbury² 2, 4, 8, 16, in mind for the duration of the last three glaciations, based upon the degree of weathering of American glacial deposits, it is possible to construct a curve similar to Penck's, but differing in length and the number of units assigned to the interglacial stages. In tabular form the data appear thus:

Estimated Duration of Pleistocene Oscillations

	Reeds, 1914			Penck, 1909		
	Units	Years	Totals	Units	Years	Totals
Post-glacial . . .	1	25,000	25,000	1	20,000	20,000
Fourth glacial . .	1	25,000	50,000	1	20,000	40,000
Third interglacial	4	100,000	150,000	3	60,000	100,000
Third glacial . . .	1	25,000	175,000	1	20,000	120,000
Second interglacial	8	200,000	375,000	12	240,000	360,000
Second glacial . .	1	25,000	400,000	1	20,000	380,000
First interglacial .	3	75,000	475,000	5	100,000	480,000
First glacial . . .	1	25,000	500,000	1	20,000	500,000
Pre-transitional .	1	25,000	525,000	1	20,000	520,000

Geologic Deposits in Relation to Pleistocene Man:
CHESTER A. REEDS.

The present known distribution of Pleistocene man through southern Europe, the Mediterranean border and Java, points to the conclusion that this early man lived along the river courses, on the adjacent uplands, in caves and grottoes which overlooked well-defined river valleys and on the seashore. Human remains have been found entombed in a few caves within the region of mountain glaciation—for example, Fréndenthal, Kesslerloch and Schweizersbild in Switzerland—but most of the finds have been made in the southern non-glaciated portions of Europe. The vicissitudes and the ameliorations of climate during the glacial and interglacial stages no doubt caused southward or northward migrations of peoples or encouraged congestion in the limestone caverns of Belgium, France, Germany and northern Spain. With the repeated formation of continental ice sheets on the

¹Leverett, F., *Zeitschrift für Gletscherkunde*, Vol. IV., pp. 282-89, 1910.

²Chamberlain and Salisbury, "Text-Book of Geology," Vol. III., p. 414, 1906.

Scandinavian plateau during periods of glaciation and their movement outward in all directions across the adjacent basins and lowlands of northern Europe, together with the appearance of ice caps on the high mountains of southern Europe, the lowering of the snow line on the mountain slopes, the development of snow caps on plateaus of but moderate relief, the extension of the glaciers into aprons and tongues on the piedmont areas and the choking of the river valleys with ice and deposits, glacial man must have felt that Snow and Ice were the governing forces. The warmer interglacial epochs were more to his liking. In the present terraces and loess deposits along the river courses and in the cave and grotto fillings, eight human culture stages have been delimited within recent years. They have been called, beginning at the bottom, pre-Chellean, Chellean, Acheulean and Mousterian as Lower Paleolithic and Aurignacian, Solutrean, Magdalenian and Azylian-Tardenoisian as Upper Paleolithic. In the cavern and grotto deposits of the Dordogne, southern France, most of the culture stages appear in regular geologic sequence one above the other. Human remains and culture stations of glacial, interglacial or post-glacial age have been found in approximately three hundred different localities.

Physiographic Features of Western Europe as a Factor in the War: DOUGLAS W. JOHNSON.

Every military campaign is controlled to some extent by the surface features of the country over which the contending armies must move. The physiography of a region may therefore profoundly affect both the detailed movements of armies and the general plans of campaign. An examination of the physiographic features of western Europe in the light of recent events enables one to comprehend more fully the strategic importance of many places mentioned in war dispatches and throws valuable light upon the question as to why the neutrality of Belgium was violated.

John Boyd Thacher Park. The Heiderberg Escarpment as a Geological Park: GEORGE F. KUNZ.

A most important benefaction to the state of New York is the beautiful John Boyd Thacher Park, opened with appropriate ceremonies September 14, 1914. During the winter of 1913-14 the American Scenic and Historic Preservation Society received word of the intention of Mrs. Thacher, widow of John Boyd Thacher, to realize her generous purpose of donating to the state a superb trust of 350 acres of land for a public park,

as a memorial of her husband, and in March, 1914, a bill was introduced and passed in the legislature accepting the gift and constituting the American Biotic and Historic Preservation Society the custodian. The park embraces the most picturesque and geologically interesting part of the Helderberg range in Albany County.

The remarkable geologic formations to be seen in this park include one of the finest exposures of the Upper Silurian and Devonian strata in the country, and other classic types of several formations, as is shown by the designations "Helderberg limestone" and "Helderberg group"; the rocks contain a great number of characteristic fossils, especially of marine forms. On the slope appear Hudson shales, and flaggy sandstones of the Hamilton formation crown Countryman Hill. The deep amphitheater at Indian Ladder has been worn out by the water of a small stream.

There is now a small museum and library in the park, and the Geological Survey has set up a bench-mark. It is hoped that very soon the cottage-building for the reception of guests will be completed, so as to afford comfortable shelter for visiting geologists who wish to study this Mecca of geologists. The library would be glad to receive geological publications having any bearing on the local conditions; such mail should be addressed to the curator of John Boyd Thacher Park, East Barre, New York. (By title only.)

The Relief of our Pacific Coast: J. S. DILLER.

The continental feature bordering the Pacific coast of the United States is a mountain belt of surpassing grandeur and composed in general of two lines or ranges of mountain elevations with a depression between. For the most part the two lines of mountains appear to be parallel with each other and the coast, the Sierra Nevada and the Cascade Ranges on the east and the Coast Ranges, including the Klamath Mountains of California and Oregon and the Olympic Mountains of Washington on the west, from the Mexican line to that of British Columbia. Cross folds connect the side ranges and separate the great valley of California from the Willamette Valley of Oregon.

The Sierra Nevada is composed of folded sediments and igneous rocks of various ages from Silurian to Jurassic, and faulted and tilted as one great block with long gentle slope to the west and steep slope to the east.

The Cascade Range is essentially volcanic and due mainly to volcanic upbuilding, though partly to upbuilding from Mount Adams in Washington

to Lassen Peak in California, but beyond these limits the older crystalline rocks rise to the surface.

The Klamath Mountains are in large measure like the Sierra Nevada in their rocks, although more fossiliferous, but differ in structure, being characterized by broadly curved thrust faults with the overthrust into the concave curve and thus toward the Pacific ocean.

The coast ranges of California and Oregon are composed almost wholly of Mesozoic and Tertiary rocks. In California the coast range rocks are greatly crushed and faulted, but in Oregon the compression has been much less intense.

At eight o'clock P.M., on December 29, the society convened in the lecture hall of the Academy of Natural Sciences and listened to the reading by Vice-president W. Lindgren of an abstract of the address of the retiring president, George F. Becker. The title of his address was "Isostasy and Radioactivity."

In addition to the papers which were read at the general sessions, the following papers were presented in the sectional meetings of the society:

"Origin of the Red Beds of Western Wyoming," by E. B. Branson.

"Some New Points on the Origin of Dolomites," by Francis M. Van Tuyl.

"Range and Rhythmic Action of Sand-Blast Erosion, from Studies in the Libyan Desert," by William H. Hobbs (by title).

"Corrosive Efficiency of Natural Sand-Blast," by Charles Keyes (by title).

"False Fault-Scarps of Desert Ranges," by Charles Keyes (by title).

"Stratigraphic Disturbance Through the Ohio Valley Running from the Appalachian Plateau in Pennsylvania to the Ozark Mountains in Missouri," by James H. Gardner (by title).

"Preliminary Paper on Recent Crustal Movements in the Lake Erie Region," by Charles E. Decker.

"Quaternary Deformation in Southern Illinois and Southeastern Missouri," by Eugene Wesley Shaw (by title).

"Old Shorelines of Mackinac Island and their Relations to the Lake History," by Frank B. Taylor.

"Some Peculiarities of Glacial Erosion Near the Margin of the Continental Glacier in Central Illinois," by John L. Rich.

"New Evidence for the Existence of Fixed Anticlines above Continental Glaciers," by William Herbert Hobbs (by title).

"Can U-shaped Valleys be Produced by Removal of Talus?" by Alfred C. Lane (by title).

"On the Origin of Monk's Mound," by A. R. Crook.

"Physiographic Studies in the Driftless Area," by Arthur C. Trowbridge (by title).

"Hemicones at the Mouths of Hanging Valleys," by Charles E. Decker (by title).

"Block Diagrams of State Physiography," by A. K. Lobeck (by title).

"Pre-Cambrian Igneous Rocks of the Pennsylvania Piedmont," by F. Bascom (by title).

"Magmatic Assimilation," by F. Bascom (by title).

"Hypersthene Syenite (Akerite) of the Middle and Northern Blue Ridge Region, Virginia," by Thomas L. Watson and Justus H. Cline (by title).

"Pyrrhotite, Norite and Pyroxenite from Litchfield, Connecticut," by Ernest Howe.

"Some Effects of Pressure on Rocks and Minerals," by John Johnston.

"Primary Chalcocite in the Fluorspar Veins of Jefferson County, Colorado," by Horace B. Patton.

"Recent Remarkable Gold 'Strike' at the Cresson Mine, Cripple Creek, Colorado," by Horace B. Patton.

"Platinum-gold Lode Deposit in Southern Nevada," by Adolph Knopf.

"Organic Origin of Some Mineral Deposits in Unaltered Paleozoic Sediments," by Gilbert van Ingen.

"Type of Rifted Relict Mountain, or Rift-Mountain," by John M. Clarke.

"Evidence of Recent Subsidence on the Coast of Maine," by Charles A. Davis.

"Basic Rocks of Rhode Island: Their Correlation and Relationships," by A. O. Hawkins and C. W. Brown.

"Acadian Triassic," by Sidney Powers.

"Geological History of the Bay of Fundy," by Sidney Powers.

"Alexandrian Rocks of Northeastern Illinois and Eastern Wisconsin," by T. E. Savage.

"Olenitangy Shale and Associated Deposits of Northern Ohio," by Clinton R. Stauffer (by title).

"Diastrophic Importance of the Unconformity at the base of the Berea Sandstone in Ohio," by H. P. Cushing.

"Kinderhookian Age of the Chattanooga Series," by E. O. Ulrich.

"Origin of the Iron Ores at Kiruna, Sweden," by Reginald E. Daly (by title).

"Origin of the Rocky Mountain Phosphate De-

posits—Preliminary Statement," by Eliot Blackwelder (by title).

"Regional Alteration of Oil Shales," by David White (by title).

"Oil Pools of Southern Oklahoma and Northern Texas," by James H. Gardner.

"Natural Gas at Cleveland, Ohio," by Frank R. Van Horn.

"Origin of Thick Salt and Gypsum Deposits," by E. B. Branson.

"Crystalline Marbles of Alabama," by Wm. F. Prouty (by title).

"Devonian of Central Missouri," by E. B. Branson and D. K. Greger.

"Olenitangy Shale of Central Ohio and its Stratigraphic Significance," by Amadeus W. Grabau.

"Hamilton Group of Western New York," by Amadeus W. Grabau.

"Extension of Morrison Formation into New Mexico," by N. H. Darton (by title).

"Geological Reconnaissance of Porto Rico," by Charles P. Berkey.

"Relation of Cretaceous Formations to the Rocky Mountains in Colorado and New Mexico," by Willis T. Lee.

"Post-Ordovician Deformation in the St. Lawrence Valley, N. Y.," by George H. Chadwick.

The annual dinner of the society was held on the evening of December 30 and was attended by 140 of the members of the society and their friends. E. O. Hovey acted as toastmaster and the speakers of the evening were Messrs. W. Lindgren, H. F. Oshorn, C. D. Walcott, C. B. Van Hise, W. W. Atwood and F. R. Van Horn.

In addition to the hospitality offered by the Academy of Natural Sciences, the Ballows of the society resident in Philadelphia entertained the Geological and Paleontological Societies and their friends at luncheon each day of the meeting and at a smoker given on the evening of the first day, at the close of the reading of the presidential address.

The officers elected for the year 1915 were Arthur P. Coleman, president; L. V. Pirsson, first vice-president; H. P. Cushing, second vice-president; Edward O. Ulrich, third vice-president; Edmund Otis Hovey, secretary; Wm. Ballock Clark, treasurer; J. Stanley-Brown, editor, and Frank R. Van Horn, librarian.

The next meeting of the society will be held at Washington, D. C., December 28-30, 1915.

THE DEPLORABLE CONTRAST BETWEEN INTRANATIONAL AND INTERNATIONAL ETHICS AND THE MISSION OF MEDICAL SCIENCE AND MEDICAL MEN¹

THE chief aim of my remarks is to point out the unique position which medical sciences and medical men occupy in the horrible war which is going on between civilized nations. International morality may possibly derive some permanent benefit from a conscious knowledge of this position. However, in order to make my point clear, I shall introduce it by a discussion of some aspects of ethics.

Moral philosophy assumes for granted that ethical relations of civilized men are safely established; it concerns itself merely with the question regarding the nature of the origin of ethical precepts. In general, it may be admitted that the vast majority of civilized men indeed do not question the correctness of ethical demands. But writers on moral philosophy fail to distinguish between intranational and international ethics. Hence, we find frequently that international occurrences are discussed from the point of view of intranational principles; international occurrences are brought before the forum of a supreme court of the world for judgment, but the merits and demerits of the cases are argued from the point of view of ethics which obtain in intranational moral relations. But the truth is that there is an abyss between the two domains of morality.

Let us first look at the status of intranational morality. The ethical relations

¹ MSS. intended for publication and books, etc., intended for review should be sent to Professor J. McKee Cattell, Garrison-Hudson, N. Y.

¹ Address delivered at the annual dinner of Columbia University Biochemical Association, March 26, 1915.

among civilized fellow men, united by bonds of race, nation or country, are firmly established. Justice and duty are deeply rooted conceptions, the compelling force of which is spontaneously recognized by all normal members of the individual community; the small fraction of dissenters consists of defectives and criminals. Sympathy, kindness, altruism and self-sacrifice are not enforceable human virtues, but are nevertheless profoundly appreciated and admired by the individuals of all civilized nations. Honesty is an indispensable virtue. In parenthesis I may, however, say here that to my knowledge "honor" is not among the general precepts of ethics. It is an artifact; it is mostly an artificial virtue of a class which considers itself as being above the simple requirements of justice and duty. It is not an unusual occurrence that in the name of honor a man may slay with relative impunity a fellowman whose home life he has dishonored.

From Sokrates to our day students of moral philosophy offered various theories concerning the nature of the principles underlying the "science of conduct." I shall not discuss the merits of the theories of Hedonism or Utilitarianism, the Law of God or the Categorical Imperative; they do not concern us here. But I have to refer to one theory which was not received with great favor and which had only a short life of popular existence. In the latter half of the last century, under the powerful influence of Darwin's theory of natural selection in the domain of biology, a systematic attempt was made by some philosophers (Herbert Spencer and others) to look upon ethics as a purely biological phenomenon. Family ties of lower animals, it was thought, developed into the ethics of civilized nations. Whether on account of the feverish social and altruistic activities which have been going on in the last decade or two and for which a biologic

theory of ethics could hardly have served as a sufficient stimulus; or whether on account of the general decadence in popular enthusiasm for the theory of natural selection in general, the fact is that the theory of biologic origin of ethics seems to have been generally abandoned in recent years. But whatever we may think philosophically regarding the nature of fundamental origin of ethics, we can practically not deny that *morality is subject to evolutionary influences*; it has undergone and is continually undergoing development. Morality manifests a continuous growth. The development of savage races into cultured, ethical nations is a matter of historical record. In fact, the progressive widening which conceptions like justice or duty are continually undergoing within the confines of a nation is practically a matter of direct observation during an individual's lifetime.

I shall dwell here especially on two elements which are operative in this process. The foremost factor in the evolutionary progress of intranational morals is to be found undoubtedly in the intellectual activities peculiar to man. The growth and development of the sciences, of arts, music, poetry, literature and religion, from their rudimentary phases into their present high states, elevated the specific human character and favored the widening and deepening of morality of any individual nation or rather the morality of the individuals of which these nations are composed. The human intellect may or may not be the primary cause of morality; but the unfolding of human intelligence and the growth of intellectual activities specifically human, are undoubtedly important elements in the growth and development of specific human morality. This connection between intelligence and morality is practically a matter of direct observation.

On this basis the further assumption is justified, that even the conscious primitive morality of primitive man did not make its appearance abruptly. It developed very slowly, parallel, to a certain degree, with the development of man in the animal stage into man with rudimentary intelligence.

I presume, then, that conscious morality did not begin abruptly, but developed very slowly, parallel with and assisted by the development and growth of human intelligence. However, important as the human intelligence may be, evidently it is not the only controlling factor of morality. We see animals acting towards their fellow creatures in a manner which, if seen in human beings, we would consider as highly ethical. We all know how animals care for their offspring. We see dogs licking the wounds of their fellow dogs—an act resembling a samaritan service. We see altruistic activities in the communities of the bees and the ants. We designate these animal activities as instincts and we have indeed no evidence that a conscious morality is at the bottom of these phenomena. We have, however, to keep in mind that the harmonious relations between animals are observed only among individuals of the same species or race, or the same drove or swarm, whether they are presided over by a bell-wether, a queen or any other single leader, or have a democratic form of government with several contending leaders. Animals belonging to different species, races or strains get frequently into ferocious fights as soon as they meet, or as soon as there is a collision of interests and instincts. There are therefore sufficient reasons for assuming that the purely animal, instinctive element is involved to a considerable degree in the moral relations between individuals of the same group of human beings which have some efficient bond in common.

Now let us look at the moral aspects which international relations present. The history of nations, civilized or uncivilized, consists chiefly of a tale of more or less ferocious wars interrupted by periods of peace. War is nothing but wholesale murder; but the men of one tribe or nation who are murdering men of another tribe or nation have no idea that they are committing crimes; on the contrary, the more civilized individuals among the fighters are honestly possessed by the conviction that they are performing a moral duty. It is true that in times of peace citizens of one country enjoy in another country most of the privileges enjoyed by the citizens of that country. This is guaranteed by treaties. There are also international laws which even presume to prescribe the mode of warfare among the signatory powers. In time of peace a sincere friendly intercourse frequently prevails between the individuals of various nations. There are numerous international reunions for the purpose of furthering human knowledge and general human interests in all lines of human endeavor. All these facts may give us the right to speak of international morality. Nevertheless, even peace, especially peace in modern times and among civilized people, is practically nothing more than a *truce* during which nations are feverishly active in preparing for the next war, preparing to slaughter their apparent friends of to-day and to lead or to drive their own men to be slaughtered. During peace the leaders of nations are engaged in their military quarters or in their chancelleries in spying upon and intriguing against the nations with whom they exchange international amenities.

In international dealings cunning and deceit are essential factors in success; it is diplomacy. Honesty has hardly a place in these dealings. Only honor is the big

word which is loudly used by those who speak for nations as units, that sham virtue in the name of which crimes are committed by the privileged classes within each nation and in the name of which hundreds of thousands of honest and innocent citizens of various nations are murdered or crippled for life in the groundless and senseless strife of nations, brought about by the ambitions of unprincipled leaders. Furthermore, international relations in time of peace, which have an ethical appearance, are held together by flimsy ties. International peace conferences, international law, and peace treaties are merely scraps of paper which are torn to shreds at first sight of a bone of contention between nations.

In a previous section I insisted, and I believe rightly, that intellectual growth and activity are most important factors in the development and growth of intranational morals. What is the value and influence of intellectual growth and activity in international morals? Highly intellectual, civilized nations fight one another with a rage, a ferocity and with an intent to kill as probably did their animal ancestors of different strains or races, hundreds of thousands of years ago. But different species of another type of animals, let us say dogs and cats, are probably fighting to-day as their ancestors fought thousands of years ago, that is, tooth and nail, the only weapons at their disposal; their physical agility, their promptly acting reflexes, the finer developed senses and their remarkable instincts did not help them in developing new weapons or new ways of fighting; they had no human intellect. But the human race? We need not go back thousands of years. It suffices to compare warfares separated only by a hundred years. I need not enter upon a comparison of the rage, brutality and barbarity with which the

Wars are conducted; in this regard the present war is surely not behind its predecessors, and none of the cultured belligerent nations are ahead of or behind the others. Perhaps atrocities are at present not so much a question of barbarity as of success and efficiency—the idols of all walks of modern life. But as to destructiveness of human life, that cardinal aim in the war of nations, the progress made in this comparatively short span of human history is immense; it reads like a fairy tale. From high in the air a human bird directs you to turn a micrometer screw one millimeter or two and a huge *shell* annihilates hundreds or thousands of your enemy. A small group of human fishes bubble up in the vicinity of a huge *leviathan*, a dreadnought, and in less than ten minutes hundreds of men and millions of dollars are forever at the bottom of the sea. In a stretch of hundreds of miles, hundreds of thousands of soldiers are moved rapidly without a hitch from one place to another where they are needed most. The success is wonderful. In barely eight months millions of people were killed or crippled, perhaps as many more were made homeless and driven into starvation and billions of dollars borrowed and wasted. And that astounding result was not accomplished as in olden times, merely by extraordinary physical force or endurance or by that virtue in which wild beasts greatly excel men, the virtue of physical courage; it was accomplished by specific human ingenuity. Mathematics, physics, chemistry and other theoretical and practical sciences have made these awful results possible. In fact, practically every kind of intellectual activity took and takes a profound part in the bitter struggle which now goes on among highly civilized nations. Historians, philosophers, literary men and others are busy contrib-

uting offensive and venomous literature about their fellow men of nations with whom their country is at war, whose friends they were and whose honors they enjoyed. Poets sing the song of profound hatred and musicians write the melody to it, or compose war marches and songs. Religion offers an extraordinarily sad spectacle. Nations having the same religion and believing in the same God, pray to Him that He may help them destroy their enemy. Think of the robber and murderer who on his most godless errand prays to God for aid and guidance!

But here I must call your attention to a paradoxical but remarkable fact. Beastly as international morality is, when nations are at war, war nevertheless unquestionably elevates the *intranational* morality. The majority of citizens in every country are not idealists; in time of peace they comply with the laws of their country and fulfill their simple duties, not more and not less. But when their country is at war, a new spirit comes over them; they become altruists, they are ready to bring sacrifices, to lose their life or to become cripples for life. Whether a country is right or wrong with regard to the merits of a particular war in the eyes of an outsider, a neutral, this has no bearing upon the moral status of the man inside his country. That status is unquestionably elevated during war, and even after the war his relations to his countrymen remain on a higher moral plane. But this applies to civilized countries only, and of these only to such countries whose civilized citizens fight its battles.

Now let me recapitulate briefly. Human morality, whatever the nature of its origin may be, was and is subject to evolutionary influences. It began in the pre-savage state of men. Its development has been and is a very slow process. In its

present state we must sharply distinguish between intranational and international ethics; there is an abyss between them. Intranational morals attained a high state. Intellectual activities of all kinds were and are most important factors in its growth. The morality in international relations, on the other hand, is generally low, and is frightfully bad when these relations are interrupted by war. War is an animal method of settling differences between two contending vicious species, and human intellectual activities greatly intensified the deadliness of the procedure. The efforts to create international laws for the purpose of restraining the ferocity of international struggles proved of little avail. We have cultured, civilized Germans, Frenchmen, Englishmen, and so on, but the world is not yet inhabited by cultured civilized men.

Apparently biological processes are operative in these horrible differences between the intranational and international states of morality. Intellectual activity is capable of efficiently assisting in the development of morality among individuals which are allied by some organic and social bonds; thus little or no resistance is offered to the beneficent intellectual influence. But individuals of different strains, with natural divergences and antagonisms, sustained by differences in education, customs, forms of law, etc., offer great resistance to the unifying influences of intellectual activity.

Accordingly, biological traits common to all animals, while some of them may exert a favorable influence upon the evolution, rate of growth and the direction of human morality, are surely not the main factors of its creation and development. On the contrary, in interracial and international relations many biological traits are profoundly inimical to a development

of proper moral ideals. Struggle for existence, uncontrolled physical strength and dexterity, love of fight, hate, rage, bravery, etc., are traits which the human race has in common with wild beasts, and an uncontrolled cultivation of these traits may often prove disastrous to all human morality. On the other hand, intelligence and intellectual activities are traits which distinguish man from beast. Their intense cultivation by civilized men has been the main cause of the high state of morality which prevails and is visibly progressing within the confines of civilized countries—the *international* ethics.

But now let us turn again to international ethics. We have seen that there is an abyss between international and intranational morality. We have seen further that war between civilized countries brings in modern times incomparably more frightful results than in previous ages, which is undoubtedly due to the astounding discoveries and inventions brought to light by the intense intellectual activities in the various cultured countries. Are discoveries and inventions, are even apparently sound intellectual activities, dangerous to international morality? Is this morality rather regressive instead of being progressive? And what can we do to make it progressive or to accelerate the imperceptible progress? The last question is the more important one, since it presents a practical and not merely an academic problem. In the following I intend to discuss some factors which may contribute in some modest way to its solution. I am fully aware, as all of you are, of the immensity of the problem, and I am aware, more than you, of the microscopical dimensions, metaphorically speaking, of your guest of the evening. But I shall act now as I always acted, upon the principle that it is neither good nor wise

to possess less courage or more modesty than that drop of water which innocently and cheerfully undertakes to drill a hole in a rock.

As one who swore allegiance to the medical tribe, I shall begin by saying that the case of international morals is very bad indeed, but it is by no means hopeless; that only hopeful men are capable of attaining desirable results; that a remedy which promises to bring some help, be it ever so small, is not to be despised, and that a sum of such remedies may save even a bad case.

It seems to me quite probable that interracial and international morals are also subject to evolutionary influences and are undergoing a developmental process; but the progress is extremely slow because it has to struggle too much against the beastly nature of man. Even the development of international morality is a slow process; it must have taken many thousands of years before it reached its present stage. The present condition of international ethics would perhaps appear to us even quite high, if we had the means to compare it with its status of hundreds of thousands of years ago. This recognition, namely, that interracial and international morals are undergoing a progressive development, but that their progress is necessarily very slow, seems to me to be a very useful one. In the first place, because it encourages us to try to accelerate this progress, be the rate of the possible increase in the acceleration ever so small and be the means at our disposal for accomplishing it ever so meager. In the second place, it suggests to us to avoid looking for means of acceleration which are far out of proportion with the rate of the evolutionary progress; it is bound to fail and even to bring a temporary reaction, as history taught us over and over again.

I do not consider it as my province to try to discuss here all sorts of means which possibly may serve to increase progress in international morality. My chief purpose is, as stated at the beginning, to bring forward the value of medical sciences and medical men as efficient factors in furthering the progress of international morality. However, before coming to it, I wish to call attention briefly to a point or two to which reference has been made before. I believe, in the first place, that it is of prime educational importance to point impressively to the fact that there is a gulf between national morality, on the one hand, and interracial and international morality, on the other hand. A confusion between the two sets of ethics may harm the former and retard the possible progress of the latter. Citizens in neutral countries at all times, and citizens of all countries in times of peace, should know, should feel it deeply in their hearts, that war has not the slightest feature of morality, that it is simply a mode of settling differences between two or more strains of the human race in the fashion of wild beasts, increased in deadliness and ugliness by the activities of human intelligence. Here is an incontestable fact which gives pain and distress to the moral man; humanity, as a whole, shows that its moral conduct is not above that of vicious animals of various species. The discussion of the question as to who began the war and who prevents its conclusion is far from the mark; it is purely academic and is borrowed from the point of view of intranational morals. Justice and law had little to do with the beginning of the war and will have very little to say with its settlement. War is carried on by brute force and is settled by it with the aid of exhaustion and starvation. The many circumstances which lead to the numerous wars are mere incidents,

but not the real cause of them. There is only one cause for all the wars and that is the possession by human beings of ferocious qualities peculiar to wild beasts, often entirely unrestrained and sometimes even directly cultivated to a higher degree.

In teaching intranational morality it ought to be made clear that physical strength, courage, dexterity and efficiency, useful and desirable as they are for the success in the life of the individuals and the nation they compose, are not moral principles. On the contrary, they may greatly magnify the evil results when used for unethical principles. Bravery and efficiency, which are most highly valued qualities in war, are qualities which are most destructive to your so-called enemy of to-day and perhaps your friend of yesterday and, moreover, perhaps of your friend of a day after to-morrow.

I now come to the chief point I wish to discuss. Short as the discussion will be, it is nevertheless the chief object of my entire discourse. I have stated above that the striking feature of this war, the great destructiveness of human life, owes its success to the employment of scientific results in carrying on the war. All sciences which may contain some practical element are contributing in some way or another to the wholesale destruction of human life. And not only the scientific results, but the scientists themselves are active at the front in laboratories improvised in large automobiles to search for new inventions and discoveries which may be of some immediate practical use or to predict the nature of the weather to be expected at different points, etc. And those who can not assist in such a direct way try to contribute to the spirit of war by spreading enthusiasm, by abusing the enemy, and by implanting hatred against it.

But there is one most inspiring exception

to this sorrowful rule. It is the utilization of the medical sciences and the behavior of medical men in the war. The results of medical investigations of the last few decades and the activities of medical men are of immense practical importance to modern warfare. In some of the former wars perhaps as many soldiers were wiped out in consequence of disease as were killed by the bullet or bayonet. The combined modern studies in pathology, bacteriology, hygiene, surgery, medicine, pharmacology, preparation of antiseptics, etc., have immensely reduced the ravages of war as far as sickness and injuries are concerned. Medical sciences and medical men are part and parcel of wars. But what is their ethical status with reference to strife of nations in comparison with other sciences, with other men of science, men of culture and education? Here is the answer.

None of the numerous important discoveries made in the medical sciences was ever used for the destruction of life or harming the enemy in modern civilized warfare.

Any discovery or invention made in the sciences or the practise of medicine, made in one of the warring countries, is freely given to the medical fraternity of a belligerent country—unless it involves a business relation over which medical men have no power. It is illuminating to read a review in an English medical journal of medical reports made at a German medical meeting held on a battlefield.

On the battlefield, on the firing line, perhaps in the midst of a hail of bullets and fragments of shrapnel, *physicians and surgeons, some of them volunteers, pick up wounded soldiers without regard to nationality, and treat friend and foe alike. It is practically of no moment to the sick and wounded soldier to which of the hos-*

pitals of the civilized belligerent nations he will be taken for treatment. The physician, as a physician, knows no difference between races and nations, between friend and foe.

And withal physicians in every one of the warring countries are as good patriots, and are as ready to sacrifice their lives in their country's struggle, as any other patriotic citizen of his beloved country, with the only difference that he, *the physician, is merely ready to die, or to be crippled for life, in the service for his country, but he is not engaged in killing or harming any one belonging to another nation or country.*

There might be a few exceptions—it would be miraculous indeed if there would be none; any large group has its exceptions. But such few exceptions can not be held up against this wonderful picture which medical men present in war. And wonderful indeed this picture is. We have seen how low international morals are at all times; we see how infamously bad it is at the time of war and especially at the present ferocious war of cultured nations. And in the midst of this inferno we perceive a group of sciences which are in intimate contact with life and with war, and which nevertheless never contribute to the degradation of interracial and international morality. We perceive, furthermore, in every belligerent nation among the combatants a group of patriotic men, brave and ready for every self-sacrifice, who do nothing but render help to those who need it, who render it as members of their particular country, but render it to foe and friend alike. Here are representatives of humanity, as a whole, here is a most encouraging example of an elevated international morality.

This wonderful fact is not my discovery; it is a fact well established, and well

known to everybody, at least ought to be known by everybody. But the calling of this fact to full consciousness of the members of our profession may render a great service to the progress of international morality.

In the dawn of history, the medical man was also the treasurer of philosophy and morals. In the middle ages when knowledge became specialized, medical men more and more devoted their activity exclusively to medical practise. On account of the inefficiency of medicine at that time, medicine lost its prestige. However, in the recent decades medicine became a science and one marvelous discovery follows another, and the efficiency of medical practise increases rapidly. Medicine makes accessible to man uninhabitable parts of the world. It prevents disease, and with increased efficiency it learns to cure it. Medical sciences and medical men rose in the estimate of discriminating civilized mankind. *Could they (medical sciences and medical men) not become again bearers of the flag of morals, especially of international morals?* In the furious struggle which is going on at present amongst civilized nations international morals lost its friends; religion, sciences and the brotherhood of mankind proclaimed by the followers of socialism failed it; medicine alone did not desert it. In times of peace and for the purpose of furthering useful knowledge medical sciences and medical practises are working in separate groups, according to their specific aims. But all medical men of various shades and groupings ought to unite for this one high aim, *ought to establish a Medical Brotherhood for the Purpose of Upholding and Accelerating the Progress of International Morality.*

Every one of the scientific and practical men in medicine in our large country ought to join with enthusiasm such a mis-

sionary enterprise. The initiative ought to be taken by our large neutral country, but we may appeal to our neutral brethren in other neutral countries to join our crusade. However, we must not approach our medical confreres in the belligerent nations as long as the war lasts, lest it may be interpreted as an attempt to weaken their patriotism and their enthusiasm for the cause of the particular countries of which they are an integral part.

ROCKEFELLER INSTITUTE FOR
MEDICAL RESEARCH

CYRUS FOGG BRACKETT

By the death of Professor Cyrus Fogg Brackett, which occurred on January 29, another link connecting the present with the past in the history of physics in this country was broken. Professor Brackett belonged to that group of physicists whose influence is now felt through their pupils in most of our universities. In the early days of his service at Princeton he was associated with Joseph Henry, who was a trustee of the college, and who took an active interest in the development of the department of physics under Professor Brackett's direction. His early studies came before the French influences had been superseded by the German, and his thinking always showed traces of that early training.

Professor Brackett, after graduation at Bowdoin College in 1859, studied medicine at the Harvard Medical School, and was graduated as Doctor of Medicine in 1863. He then returned to Bowdoin as a member of the faculty, and soon became professor of chemistry and physics. In 1873, on the advice of Professor Henry, he was called to Princeton as professor of physics. His coming to Princeton coincided with the foundation of the John Green School of

Science, and with a greatly increased interest in all scientific studies. He became at once the trusted adviser of the board of trustees in their endeavors to increase and improve the instruction in scientific subjects, and he was influential with the faculty in all matters connected with the development of the curriculum.

The physical laboratory as he found it had no equipment for research, and but little for demonstration. He felt it was his duty to devote himself to the improvement of the equipment, and to the organization of courses of lectures and laboratory instruction. As new apparatus came in he would put it together and test it, and when new apparatus was wanted which could be better made than purchased, he would construct it with his own hands. He was very skillful in all mechanical work, and much of the apparatus which he made is still in use.

At the same time he gave himself with entire devotion to his labors as a teacher. He thoroughly believed that physics should form an essential part of every student's course of study, and realized that if this were the case the course in physics should not be confined to the dry details of the subject, but should rather present the philosophy of nature. Owing to the breadth of his education, and to his unlimited interest in all scientific and philosophical questions, he was able to illuminate his subject with illustrations drawn from other sciences, and from the practical applications of science in the arts. His courses of lectures were not only instructive, but inspiring, and many of his students remember him with affection and respect as the most stimulating influence in their intellectual life.

Professor Brackett's interests were strongly excited by the development of electrical science, and of its applications

to the comfort and convenience of life. He was acquainted with many of the great inventors by whom those applications have been made, and he became connected with some of their principal achievements as an expert adviser. He was occupied for several years as an expert, both in the laboratory and in the courts, with the questions arising in the contest concerning the invention of the telephone. He was thus led to give instruction in the engineering side of electrical science, and ultimately in 1889 to undertake the development of a school of electrical engineering. The course in this school, as he planned it, is designed for graduates, or for others already properly qualified by a sufficient knowledge of mathematics, physics and chemistry. One of its principal features is the emphasis laid upon the advanced study of general electrical science. His aim was to give his students a thorough general knowledge of their science, so that after a short experience in the practise of their profession they might qualify for positions in which scientific knowledge is particularly needed. Although, as he appreciated would be the case, the membership of this school has never been large, many of those who have gone out from it have justified the plan on which it was organized by rapidly attaining important places in the profession of electrical engineering.

Professor Brackett was for many years a member of the American Association for the Advancement of Science, and in 1886 was vice-president of section B. He was also a member of the American Philosophical Society. His knowledge of medicine and his general interest in the public welfare led to his appointment as a member of the State Board of Health of New Jersey. He served as president of this board for ten years. He was also for many years a member of the sanitary committee of

Princeton University, and was its responsible member in charge of the infirmary.

In 1908 he insisted on retiring from active service and was made professor emeritus. He at once turned his attention to research, for which he was so well fitted, and from which his devotion to professorial duties as a teacher had for so many years excluded him. He employed his technical skill in making optical preparations, and at last became interested in the construction of a ruling engine for the construction of diffraction gratings, of the sort known as echelette gratings. He devised a new method for the mechanical grinding of the screw, by which most of the hand labor that was needed in the methods previously used was avoided, and before his death he had the satisfaction of seeing the engine which he constructed producing gratings of satisfactory quality. With very little additional labor it will be fitted to do the work for which it was designed.

Professor Brackett was gifted with a most winning personality. He made friends of his colleagues and his pupils. The gift of the Palmer Physical Laboratory by Mr. S. S. Palmer, and its endowment by Mr. D. B. Jones and Mr. T. B. Jones, are monuments of the affectionate regard which he inspired in some of those who knew him. He was a wide reader, and an ingenious speculator on physical questions, and was always ready to contribute of his knowledge to those who came to him for information and advice. He will be remembered by all who came within the range of his influence as an inspiring teacher, an affectionate friend and a good man.

W. F. MAGIE

GEOGRAPHICAL MEETING IN NEW YORK

The second joint meeting of the American Geographical Society and the Association of American Geographers will be held in New

York, Friday and Saturday, April 9 and 10, 1915. With the exception of Friday evening, the sessions will be held at the society's building, Broadway at 156th Street. President Dodge of the association will preside at the sessions. The joint meeting will be called to order on Friday morning by Mr. John Greenough, vice-president and chairman of the council, American Geographical Society. The Park Avenue Hotel at the corner of 33d Street and Park Avenue, will be headquarters for association members. The American Geographical Society has very generously asked all association members to be their guests at the hotel during the meeting, from Thursday afternoon, April 8, to Saturday afternoon, April 10. The arrangements make it desirable to dine together at hours to be announced at the session on Friday. It is hoped that as many members as possible will arrive on Thursday in time for dinner and the social gathering in the secretary's room at the hotel during the evening. The American Geographical Society has invited all members of the association to luncheon on both Friday and Saturday noon at a restaurant close to the society's building. Mr. George A. Plimpton has invited the members of the association, their wives, and all workers in geography in attendance at the meeting to meet at his home on Friday evening. Mr. Plimpton will speak informally on Early American Geography, and exhibit his complete and interesting library of early American texts in geography.

The scientific program is as follows:

FRIDAY MORNING SESSION (FROM ELEVEN O'CLOCK TO TWELVE-THIRTY)

"The Coast of New Caledonia," by W. M. Davis.

"Geography of the Navajo Country," by H. E. Gregory.

FRIDAY AFTERNOON SESSION (FROM TWO O'CLOCK TO FIVE)

"Utah, the Oasis at the Foot of the Wasatch," by Mark Jefferson.

"The Geographic Factor in Agricultural Industries," by C. S. Scofield.

"Origin of Some Desert Basins," by N. H. Darton.

"The Natural History of Ancient Vinland, and its Geographic Significance," by M. L. Fernald.

FRIDAY EVENING SESSION (AT 8:30, 61 PARK AVE.)

"Early American Geography," by George A. Plimpton.

SATURDAY MORNING SESSION (FROM TEN O'CLOCK TO TWELVE-THIRTY)

"Argentina and the Argentines," by Bailey Willis.

"Winter Weather as a Factor in the Great War," by R. DeC. Ward.

"The Muir Glacier in 1911 and 1913," by Lawrence Martin.

PACIFIC ASSOCIATION OF SCIENTIFIC SOCIETIES

At the Seattle meeting of the Pacific Association in May, 1914, the new constitution for a Western Division of the American Association for the Advancement of Science was accepted and recommended to the constituent societies for their adoption. It was determined that a two thirds vote would be necessary for adoption; that if this vote was secured before the meeting of the American Association at San Francisco in August, 1915, the work of the Pacific Association would be given over to the Western Division at the end of the August meeting, provided the Western Division was organized and ready at that time to continue the work of the Pacific Association. On March 20, 1915, the required two thirds vote was secured, and the Pacific Association is now ready as soon as the constitution is signed by the officers of the voting constituent societies to turn over the work to the new Division at the end of the August meeting of the American Association. The following societies adopted the new constitution in the following order: Biological Society of the Pacific Coast, Pacific Coast Paleontological Society, The Cordilleran Section of the Geological Society of America, The Seismological Society of America, Astronomical Society of

the Pacific, The Technical Society of the Pacific Coast, The Cooper Ornithological Club, California Academy of Sciences, Puget Sound Section of the American Chemical Society, The Pacific Slope Association of Economic Entomologists, San Francisco Society of the Archeological Institute of America, and the San Francisco Section of the American Mathematical Society—twelve societies in all. The following societies rejected the constitution: The Philological Society of the Pacific Coast, and the San Francisco Section of the American Chemical Society. The Geographical Society of the Pacific did not reply. The Pacific Coast Branch of the American Historical Association will decide the question late in 1915.

Dr. Campbell, president of the American Association, has already appointed a committee to effect the organization of the division, and it will be ready in August to receive the work and the archives of the Pacific Association which will in this manner terminate a five years of active work.

J. N. BURMAN,

Secretary of the Pacific Association

SEATTLE,

March 30, 1915

SCIENTIFIC NOTES AND NEWS

DR. IRA REMSEN, president emeritus of Johns Hopkins University, will deliver the principal address at the formal opening of the new chemistry building of the University of Minnesota, on May 24.

At the recent commemoration day exercises at the Johns Hopkins University there was presented to the university by a committee of which Dr. William S. Halsted, professor of surgery, was chairman, a portrait in oil by Mr. Seyffert, of Philadelphia, of Dr. Franklin P. Mall, professor of anatomy in the university. Dr. Lewellys L. Barker, professor of medicine, made the presentation address.

PROFESSOR CHARLES S. WILSON, of the Cornell School of Agriculture, has been nominated by Governor Whitman as New York state commissioner of agriculture.

OFFICERS of the Royal Astronomical Society have been elected as follows: *President*, R. A.

Sampson, astronomer royal for Scotland; *Vice-presidents*, J. W. L. Glaisher, Esq., Colonel E. H. Hills, W. H. Maw, Esq., H. H. Turner, Savilian professor of astronomy, Oxford; *Treasurer*, E. B. Knobel, Esq.; *Secretaries* A. S. Eddington, Plumian professor of astronomy, Cambridge, Alfred Fowler, Esq.; *Foreign Secretary*, Arthur Schuster, Esq.

NINE members of the American Red Cross Sanitary Commission, on their way to Serbia to fight the ravages of typhus and other contagious diseases in that country, sailed on April 3 on the steamship *Duc D'Aosta*, for Naples. They were: Dr. Thomas W. Jackson, chief sanitary inspector; Dr. Hans Zinsser, bacteriologist; Dr. Andrew W. Sellards, Dr. George C. Shattuck, Dr. F. B. Grinnell, Dr. B. W. Caldwell, W. S. Standifer, Luis de la Pena and Hobart D. Brink. Dr. Richard P. Strong, the director of the commission, will meet them at Salonika. The expenses are being paid jointly by the Rockefeller Commission and the Red Cross.

On the retirement of Mr. Otto H. Tittmann from the superintendency of the United States Coast Survey, recently announced from Washington, Dr. Henry S. Pritchett, president of the Carnegie Foundation, writes: "He entered the Coast Survey forty-eight years ago, and received his scientific training, as was the custom in that day, in the survey itself. Passing through all the divisions of scientific work, including hydrography, geodesy, terrestrial magnetism and tidal observation and prediction, Mr. Tittmann reached the highest scientific position in the survey and became in 1898 assistant superintendent, and in 1900 superintendent of the Coast and Geodetic Survey. His administration of this great post has been admirable, both from the scientific and the administrative point of view. His contributions to the determination of the figure of the earth, to the fixation of the boundary line between Canada and the United States, and his part in international geodesy have done credit to the country. With all his distinguished ability and service, he has united a modesty as fine as it is rare. It is a fortunate country which has such public servants."

DR. ARTHUR W. GOODSPEED, professor of physics in the University of Pennsylvania, has returned from Marburg, Germany, where he intended to pursue research work.

PROFESSOR LYNDY JONES, of Oberlin College, is planning to take a party of twelve students with an assistant to the coast of Washington, leaving Chicago June 21. Seven weeks will be spent studying the ecology of the region. From Neah Bay to Moclips the party will have as guides Guilliute Indians, making use of a gasoline launch and canoes along the coast. Special scientific investigation will be made of Coelentera, Echinodermata and Mollusca which abound between the tides. In addition, particular attention will be given to the kelp beds, the trees and bushes of the coast and the land animals of the islands. Members of the expedition will later visit the exposition at San Francisco.

THE address to the graduating class of the Michigan College of Mines is to be given this year by Professor James F. Kemp, of Columbia University, on April 18.

DR. JOHN F. ANDERSON, director of the hygienic laboratory, U. S. Public Health Service, addressed the Minnesota Pathological Society, on March 30, at the Institute of Anatomy. His subject was: "The Present Status of Our Knowledge of the Etiology and Distribution of Typhus Fever."

DR. EDITH J. CLAYPOLE, research associate in pathology in the University of California, died on March 27, in Berkeley, California. Dr. Claypole was well known as a teacher and investigator in biology and during recent years for her work on the differentiation of streptothrix infections in human beings, and on immunization against typhoid fever.

J. FOSTER CROWELL, known as an expert in railroad construction and hydraulic engineering, author of works on engineering subjects, including "Training a Tropic Torrent," "How Holland Was Made" and "Modern Wharves and Harbor Facilities," died in New York City, on March 29, aged sixty-seven years.

MISS MARY E. GARRETT died on April 8, in the sixty-second year of her age. Miss Garrett

took an active interest in education and gave large sums to the Johns Hopkins Medical School, Bryn Mawr College and the Bryn Mawr School for Girls in Baltimore.

SIR JOHN CAMERON LAMB, long connected with the British post office and chairman of many departmental committees, the author of works dealing with improvements in the use of the cable and the wireless telegraph and the construction of lifeboats, died on March 30, at the age of sixty-nine years.

THE Royal Astronomical Society has by a vote of 59 to 3 passed a resolution as follows:

That this meeting approves of the admission of women as fellows and associates of the society, and requests the council to take all necessary steps to render their election possible.

THE twenty-fourth session of the Marine Biological Laboratory of Leland Stanford Junior University at Pacific Grove, California, will begin on Monday, May 24, 1916. The regular course of instruction will continue six weeks, closing July 3. Investigators and students working without instruction may make arrangements to continue their work through the summer. The laboratory will be under the supervision of Professor G. O. Price, instructor in charge.

PROFESSOR J. PAUL GOODE, of the University of Chicago, has just issued the map of Africa in two forms, physical and political, and the fourth pair in the series of wall maps for colleges and schools upon which he has been at work for some years. The maps are 46 x 66 inches in size, the physical map printed in twelve colors, the political map in nine colors. These maps are entirely new, from original sources, and represent an earnest effort to achieve the highest quality of work in the map makers art.

THE American Ornithologists' Union will meet in San Francisco, May 18-30. Eastern members will leave New York on May 6, reaching San Francisco on the evening of May 15. Two days, May 10-11, will be spent at the Grand Cañon, and two days and a half at Los Angeles. The sessions will be held at The Inside Inn, within the Exposition Grounds, with the annual dinner on the even-

ing of May 18. Friday, May 21, will be devoted to a trip to the Farallon Islands, on the U. S. Fisheries steamer *Albatross*, and other trips will be arranged in accordance with the number of visitors and their inclinations.

THE Southwestern Anthropological Society was organized on March 27, at Santa Fe. The report of the organization committee was unanimously adopted and Dr. Livingston Farrand, president of the University of Colorado and formerly professor of anthropology at Columbia University, was elected president. Dr. F. E. Mera was elected vice-president; Paul Radin, secretary, and Judge R. H. Hanna, treasurer. The members of the committee of research elected were Professor P. E. Goddard and Mr. Niels Nelson, of the American Museum of Natural History, New York City; Professor Franz Boas, of Columbia University; Professor A. L. Kroeber, of the University of California; Professor A. Tozzer, of Harvard University, and Mrs. Stevenson, of the Bureau of American Ethnology. Drs. Farrand and Radin are ex-officio members of this committee.

THE magnetic survey vessel *Carnegie* left Brooklyn on March 6, bound on a two years' cruise, via the Panama Canal. The region of work will be chiefly in the Pacific Ocean and in the south Atlantic and south Indian oceans. A complete circuit of the earth between the parallels of 60°-85° south is to be attempted, November, 1915-March, 1916, starting out from Port Lyttleton, New Zealand, as a base. The *Carnegie* is commanded on this cruise by Mr. J. P. Ault, who will be assisted in the scientific work by Dr. H. M. W. Edwards (second in command) and by observers Johnston, Luke and Sawyer. Dr. Mauchly accompanies the vessel as far as Panama in order to assist in the inauguration of the work in atmospheric electricity which, with the aid of new appliances, is to be made a special feature on this cruise.

THE appeal for subscriptions to the Sir William White Memorial Fund has resulted, we learn from *Nature*, in a sum of \$15,000, contributed by 455 subscribers. The committee of the fund has decided that the most

suitable form which the memorial could take would be the establishment of a research scholarship in naval architecture to be named after Sir William White; and it has been arranged to hand over to the council of the Institution of Naval Architects the greater part of the funds subscribed so that a sum of at least £100 a year shall be available for the scholarship, which will be administered by the council of that institution. In addition, a medallion portrait will be placed in the new building of the Institution of Civil Engineers, and, finally, at the suggestion of Lady White, a donation of one hundred guineas has been made to the Westminster Hospital, where Sir William White passed away.

THE Washington Academy of Sciences is giving a series of lectures in the auditorium of the New National Museum, to which the public is invited. All these lectures are illustrated by lantern slides. The program is as follows:

- March 18—"The Volcano Kilauea in Action,"
by Arthur L. Day.
March 25—"Nematodes, their Relations to Man-
kind and to Agriculture," by N. A. Cobb.
April 1—"High Explosives and their Effects,"
by Charles E. Munroe.
April 8—"Insects and their Relation to Disease,"
by W. D. Hunter.
April 15—"The Earth," by R. S. Woodward.

SOME years ago the buildings of the aquarium at Rothesay, which was for a time one of the well-known "sights" of the Clyde, were taken over by the Marquis of Bute. The buildings have through his generosity provided a local habitation for the Buteshire Natural History Society, of which Dr. J. N. Marshall is president, while they have also served to house a valuable and developing museum collection of the local fauna and flora. Lord Bute has now installed a small laboratory for biological research and provided the most necessary equipment, including a motor boat. Mr. L. P. W. Renouf, of Trinity College, Cambridge, has been placed in charge and, as he is desirous of making the laboratory a thoroughly convenient center for research work

on the wonderfully rich marine fauna and flora of the Clyde estuary, he will be grateful for the gift of books and pamphlets bearing upon marine zoology and botany.

THE sundry civil act as passed by the last session of congress contained appropriations of \$1,355,520 for the United States Geological Survey. Most of the appropriations for the Survey are included in this great government supply bill, but in addition to the above-stated amount \$40,000 was appropriated in the legislative bill for rents, so that the total amount appropriated is \$1,395,520. The principal items in the appropriations for the Geological Survey for the fiscal year ending June 30, 1916, are as follows:

Topographic surveys	\$350,000
Geologic surveys	350,000
Mineral resources of Alaska	100,000
Mineral resources of the United States ..	75,000
Chemical and physical researches	40,000
Geologic maps of the United States	110,000
Gaging streams, etc.	150,000
Surveying national forests	75,000

The bill also appropriates \$175,000 for printing and binding survey reports, to be expended by the public printer, and \$1,500,000 for the new Interior Department building, which is to accommodate the office of the Secretary of the Interior, the Geological Survey, the Reclamation Service, the Land Office, the Indian Office and the Bureau of Mines, all bureaus of the Interior Department whose work is closely related to that of the survey and among all of which there is more or less constant cooperation. The total cost of the new building has been fixed at \$2,596,000.

THE test and certification of watches, chronometers and other timepieces has been carried on for many years at the Kew Observatory in England, at the Besançon Observatory in France and at the observatories of Geneva and Neuchâtel in Switzerland, but no such tests have been made for the public in this country, except for a few years at Yale University many years ago. This line of work is now started at the Bureau of Standards, and Circular No. 51, entitled "Measurement

of Time and Tests of Timepieces," has just been issued, giving the regulations under which the tests will be made, the methods employed, together with sections on the use and care of watches, and on standard time and the sources of reliable time standards with which one may make frequent comparisons of his watch. This first edition of the circular announces the regulations for the test and certification of watches only; the test of other timepieces will be taken up later. For the purposes of test watches are divided into two classes, designated as A and B, adapted to watches adjusted for five positions and three positions respectively. The former test lasts 54 days, the latter 40 days. Both tests include a test of the temperature compensation of the watch, at temperatures of 5°, 20° and 35°. In the Class A test is also included an examination of the isochronism adjustment of the watch. Four tests a year are carried out, beginning on the second Tuesday in January, April, August and October respectively. The daily rates of the watches under the various conditions are determined within about 0.1 second. If the performance of a watch is within certain tolerances set for the different conditions, a certificate is granted showing the results of the test. If a watch fails to meet the requirements, a report is rendered showing wherein it fell short of the tolerances and giving its actual performance in the trial. Watches may be submitted by manufacturers or jobbers of watches, by retail dealers, or by individual owners of the watches, a fee being charged which is estimated to cover the actual cost of the test. It is expected that the tests will be especially valuable in cases where watches are to be used for scientific purposes or exploration, and also to purchasers of high-grade watches in giving them assurance that the watch is reasonably adjusted and in good condition at the time of the test. Copies of the circular and also of the application blank which must be filled out by those submitting a watch for test may be obtained upon request directed to the Bureau of Standards, Washington, D. C.

We learn from *Nature* that the movement started last year for the establishment of a Radium Institution in Manchester met with a generous response from the public. Thanks to the assistance of public men and the press, the committee that was appointed to carry out the scheme was able to collect a sum of about £30,000. The radium department was established at the Royal Infirmary, and began work on January 1 in a number of rooms that had been equipped at a cost of £1,000, and started with about 800 milligrams of radium metal. The contract for the radium, which cost about £21,000, was given to an American firm, and its delivery was not therefore interfered with by the outbreak of the war. In order to ensure the maximum efficiency, the radium committee, acting on the advice of Sir E. Rutherford, Sir Wm. Milligan, and other experts, took control of the equipment of the laboratories; and the standardization of the radium was done in the physical laboratories of the University of Manchester. The committee has also drawn up a scheme for the distribution of radium either in the solid form as applicators, or as emanation tubes from the liquid form, to the other hospitals in Manchester and the district. Dr. Arthur Burrows is the radiologist at the infirmary responsible for the administration, Mr. H. Lupton is the physicist in charge, and Sir E. Rutherford acts as consulting physicist to the department.

ADMIRAL PRARY's arctic ship, the *Roosevelt*, has been sold and it is said that after it has been fitted with oil-burning machinery and other improvements, it will be sold to the Bureau of Fisheries of the Department of Commerce and Labor. The ship will be used in connection with the fisheries service in Alaskan waters, and will proceed through the Panama canal as soon as the refitting has been completed.

THE geologists of the University of Texas, including the staffs of the school of geology and the bureau of economic geology, have organized the Texas Geological Club. The purpose of this club is to stimulate interest in geological matters at the university and in geologic research. Monthly meetings will be

held, and papers bearing on matters of geologic interest will be presented. The membership includes the following: F. W. Simonds, J. A. Udden, F. L. Whitney, C. L. Baker, H. P. Bybee, D. J. Jones, W. F. Henneger and Alexander Deussen.

It is stated in *Nature* that the committee of users of dyes appointed to confer with the British Board of Trade as to a national dye scheme has come to a unanimous decision in favor of the adoption of a scheme which differs in certain important respects from those of the scheme previously made public. The proposal is to form a company with an initial share capital of £2,000,000, of which £1,000,000 will be issued in the first instance. The government will make to the company a loan for twenty-five years corresponding to the amount of share capital subscribed up to a total of £1,000,000, and a smaller proportion beyond that total. The government advance will bear interest at 4 per cent. per annum, payable only out of net profits, the interest to be cumulative only after the first five years. In addition, and with the desire of promoting research, the government has undertaken for a period of ten years to make a grant to the company for the purposes of experimental and laboratory work up to an amount not exceeding in the aggregate £100,000.

UNIVERSITY AND EDUCATIONAL NEWS

UNDER the will of the late General Charles H. Pine, recently published, Yale College will eventually receive an addition of \$150,000 to the \$50,000 scholarship fund established by General Pine about three years ago. The will also provides for the creation of a fund of \$250,000 to be devoted to manual training of Ansonia boys and girls.

By the will of General William D. Gill, of Baltimore, the Johns Hopkins University is made residuary legatee after the death of his wife. The bequest is to be used for the establishment of a chair of forestry.

AMONG the gifts recently received by Harvard University is one from Mrs. Samuel Sachs, of \$2,500 for the purchase of a work

or works of art for the Fogg Art Museum, and one of \$3,005 from various donors for the Arnold Arboretum.

THE sum of \$25,000 has been contributed by Mr. P. S. du Pont toward the University of Pennsylvania Museum extension building fund, which now amounts to more than \$100,000. As soon as the fund amounts to half a million dollars, the building of the next extension will be started.

PROFESSOR JOHN A. MILLER, director of the Sproul Observatory of Swarthmore College, has recently been elected vice-president of the college.

DR. RUDOLF HÖBER has been appointed to the chair of physiology at Kiel vacant by the removal of Professor A. Bethe to Frankfurt.

DISCUSSION AND CORRESPONDENCE

ON THE PROPOSED REORGANIZATION OF DEPARTMENTS OF CLINICAL MEDICINE IN THE UNITED STATES

TO THE EDITOR OF SCIENCE: Although Dr. Bevan's letter, published in *SCIENCE* in answer to Dr. Meltzer's, warns college presidents, laymen and university professors who are heads of laboratories to await patiently the findings of committee, consisting largely of practising clinicians, which is now considering the subject of the reorganization of the teaching of clinical medicine, yet in spite of the implied preemption of the subject it seems possible that even a university professor may be allowed to express his views.

For many years scientific work has been accomplished in this country in laboratories associated with the medical sciences, work which has received world-wide recognition. In other instances, clinicians have associated themselves with laboratory men, and have produced results which are known in the great foreign clinics. One might refer to the work of Coleman, of Joslin and of Howland as examples. This represents the cooperation of the laboratory and the hospital which has yielded and is yielding valuable results. There can be no question of the value of sympathetic and friendly cooperation of this sort.

The third stage, that of independent re-

search by the clinician, is the goal toward which the better schools of the country are striving to approach. It is this which led to the recent conditional gifts of \$1,400,000 and \$750,000 from the Rockefeller Foundation to the Johns Hopkins and to the Washington University. The spirit of modern medicine is that of scientific inquiry into the cause and cure of disease. This spirit can only be imparted by men who are themselves makers of modern knowledge. It is said that science does not explain all things and it is asked why should science be followed? The answer to this question should be, more science, to explain the unknown facts.

It is frequently set forth that there are two subdivisions of medicine, medicine as an art and medicine as a science. The impression is conveyed that medicine as a research science is not the object of a department of medicine. For this reason, the cooperation of the scientific departments is often asked. Innumerable schemes for "correlation" have therefore been presented to various medical faculties throughout the country. "Correlation" in this interpretation signifies that the scientific departments are to give instruction in the clinical years along the lines of the developments of modern scientific research. The oft-repeated request for correlation in this sense shows that there is something lacking in the clinical instruction which should be there.

The medical students of the United States are thoroughly grounded in the fundamental sciences during the early years of association with their schools. The fundamental sciences are largely unknown to the rank and file of the clinical teachers. This leads the latter to ridicule the knowledge which the students, with much labor and care, have sought to acquire. One of two results follow; either the student joins the instructor in belittling the laboratory teaching, or the student, being better informed than the instructor, feels ill satisfied with his opportunities.

The situation is something like this. There is a true scientific medicine based upon the application of research medicine in the clinic. The modern medical student is entitled to this

kind of instruction for the fulfilment of his highest development. Can he get this? The answer is found in the argument offered in England as well as in the United States, that the department of medicine should be devoted to the teaching of medicine as an art. It follows that the direction of research is outside its capacity.

Let this problem be examined a little more closely. Many medical schools have recently purchased costly string galvanometers for use in affiliated hospitals. This apparatus is of service in certain diagnoses. As an instrument of research it might perhaps yield a brilliant discovery if used by a man who had been constantly engaged in the study of the phenomena of the circulation during a period of say five years. To the ordinary operator it has no more power of revealing new truths than would a Morse telegraphic outfit.

The truth of the matter is that, as a country, we have produced few men in medical science. This is frankly because the teaching of medicine has not been in accordance with modern science. The staff of the medical department should consist of men, themselves devoted to medical science, capable of carrying it on, brought up in the air of it and blessed by the enthusiasm of it. Such men should be produced under the leadership of the professor of medicine.

The true remedy is that the clinical departments furnish instruction along modern scientific lines. Other remedies are only temporary palliatives. The medical school owes a duty to the public. Personal ambition, even though unconsciously exercised, should not be allowed to frustrate the fulfilment of the duty to the community which the college lives to serve.

The schools are brought face to face with the question whether their policy will be to advance along modern lines or stand still yet a little while.

It is impossible in any faculty to approach this subject without hurting the feelings of true and honorable men, men who deserve well of their country and who are not to blame for the present situation brought about by an

altered trend of educational thought. It is, therefore, extremely difficult to speak of these matters without seeming to be both unkind and unjust. On the other hand, if no word is spoken, blame for cowardice is incurred.

It is the current opinion of the laboratory departments that medicine should be taught as a science by men who are scientific investigators. It is their hope that departments of medicine can be recognized so that this reform can be put into effect. We must think not of ourselves but of the present and the future. Only reorganization along modern lines will bring the best trained students. One needs but have one's touch on the scientific pulse of the country to realize the absolute verity of this statement.

The medical teaching of Friedrich Müller is conceded to be the best in the world. This is his own description of it.

At half-past eight I go to my institute, at ten to the wards. May I explain? My clinic (at 9 A.M.) is in the theater and to this theater the patients are brought, and I show the patients before my students and examine and explain the cases. This takes an hour, and then I go with a part of my students, which changes every day, to the wards and instruct them personally. This takes another hour. Then I go round the wards with my assistants and it is one or half-past one when I have finished. At least three times and in the winter term four times a week I go to my institute in the afternoon and give a general lecture. I lecture upon the diseases of the brain, the diseases of metabolism, diseases of the respiratory system and so on over certain parts of the whole province of medicine. My assistants are in part municipal, paid for by the state. I have one assistant in biological chemistry, another in chemistry, one working on nervous diseases, one doing bacteriological work and making a vast number of tests, Wassermann tests and so on. If I have a case, say, of typhoid fever, I give the proofs to the assistant last named, if I have a nervous case, to the nerve specialist. Any question of metabolism or chemistry I work out with my chemical assistants, and I work with them. I go on with research work and I do this work in connection with my assistants. . . . I have my own laboratories. I have a large laboratory for chemistry. I have a laboratory for physical examinations and especially for pathological anatomy, then one for bacteriology and for

the Wassermann test, and so on. We have a large building for laboratory work connected with my clinic and governed by me. . . . Is it really necessary to incur such great expenses? Would it not be possible to conduct the school for the common practitioner in the old well-established manner? No. The general medical practitioner has always and everywhere to deal with the highest good, with the health of his fellow creatures and he must become more and more even in the remotest village the promotor of public health and therefore he must be an educated man. In his responsible vocation he must have some ideal which elevates him above the daily sorrows and disappointments of life. And he will find his refuge in his science. Only a good scientific education will enable him to follow the progress of medicine with critical understanding. Without a good scientific training he would sink into mere routine.

Let these words sink into the understanding.

Objection may be raised that no man in America is fit to conduct a clinic in any way similar to Friedrich Müller's. To say that is to insult the intellectual capacity of the country. It is admitted to-day that we lead the world in biology and in biological chemistry. To state that it is impossible to conduct medical instruction along the lines of what is admitted to be best, is inexcusable sophistry.

In conclusion, it is suggested that departments of medicine be organized under the leadership of individuals who will develop scientific research, and who will be placed upon a salaried basis with prohibition of private practise during a period of five years. The facilities for medical research in the hospital should be freely open to all at present in connection with the schools. The proper development of this scheme would take the whole of a man's time during the first five years. At the end of that time it will be evident whether it is necessary for a master of medical science to have that sharpening of the wits which an outside consulting practise is supposed to produce.

These words have not been written in a spirit of personal antagonism to men of the older order, for the writer has lived long enough to desire to avoid arousing such antagonism. But he feels that they bear the mes-

sage of the modern educational world and that he would be recreant to his sense of truth if he held his peace.

GRAHAM LUSK

LETTER FROM PROFESSOR ED. CLAPARÈDE

J'APPRENS de divers côtés que "Science" a reproduit une nouvelle d'après laquelle j'aurais dû démissionner de mes fonctions à l'Université de Genève. Cette nouvelle est entièrement inexacte. La presse allemande, qui l'a d'abord propagée, m'a confondu avec un de mes cousins, professeur de droit germanique à Genève; celui-ci a en effet été suspendu provisoirement de son enseignement pour avoir, dans son cours, reproché à la population civile belge d'avoir tiré sur ses agresseurs allemands.

Au moment où ces incidents se sont produits, j'étais mobilisé, à la frontière, comme médecin d'un bataillon de montagne. J'y suis donc entièrement étranger. Mais, puisque mon nom a été prononcé, permettez-moi d'ajouter, pour éviter tout malentendu, que je ne partage aucunement la manière de voir de mon cousin, dont la mère est allemande, et qui a été lui-même élevé en Allemagne, ce qui explique suffisamment son manque d'objectivité en cette affaire.

ED. CLAPARÈDE

FACULTÉ DES SCIENCES DE GENÈVE

SCIENTIFIC BOOKS

Text-book of Embryology. Vol. I. Invertebrata. By E. W. MACBRIDE, M.A., D.Sc., LL.D., F.R.S. London, Macmillan & Co. 1914. Pp. 692.

"The design of this text-book of embryology of which this is the first volume, is to associate the structural development of embryos with broad generalizations of what is known of their physiology. Attention will be drawn, for instance, to the correlation between the function of certain organs of a larva and its habit of life, and, in a more general way, between function and habit and the course of development. Reference will be made to some of the more striking results obtained by experimental embryological research. Attention will be drawn to gaps in our knowledge which indicate promising fields for research."

These words by the editor, Professor Walter

Heape, introduce a work which promises to be as useful to the embryologist as is the Cambridge Natural History to the zoologist. Two other volumes are to be included in the work, one on the "Lower Vertebrata" by Professor John Graham Kerr and one on the mammals by Mr. Richard Assheton, both announced to be in press.

The volume before us measures 692 pages and is illustrated by 468 well-executed figures. The treatment is necessarily very succinct, as will be apparent when we consider that Balfour's treatment of invertebrata in his "Comparative Embryology" of 1885 was almost equally extended, and that Korschelt and Heider devoted 1,500 pages to the same groups in 1890-93. Professor MacBride's treatment, of course, includes later investigations also. In each phylum at least one type is selected for detailed description of the entire life history, and in the larger phyla each class may be so represented. Comparative data are then discussed; the experimental embryology is then treated, in some groups at least; and in conclusion the phylogeny of the phylum is considered from the point of view of the developmental history. This method admits both of considerable detail in the treatment of the type forms, and also of succinctness in the consideration of the comparative data. It avoids the vicious habit of constructing life histories from pieces of different ontogenies, and at the same time preserves some advantages of the comparative method.

The descriptive part of Professor MacBride's book is well done, and will be most useful. Special note should be made of the adequate descriptive treatment of cell-lineage hitherto lacking in text-book form. A selected list of literature follows each chapter, and the index appears to be very full. The practical embryologist will find methods of study in many places.

In such a book very much depends on the point of view of the author. The material is so great that rigid selection has to be practised: what is to be rejected, what retained and what principles are to be emphasized? There is no doubt about the point of view of Pro-

fessor MacBride; he stands firmly by the descriptive method, and the phylogenetic point of view as fundamental. All else is secondary: "It is, therefore, of the essence of *comparative embryology* to separate the fundamental ancestral traits of development from the superficial and secondary, and this is the task that has been patiently pursued for the last thirty years." If the results are considered disappointing, this is due largely to the human failing of lack of patience; and if divergences of opinion with reference to phylogenetic problems seem irreconcilable, in what better position are the adherents of the experimental analytical school? Are not opinions equally diverse and irreconcilable there? "The real truth is that experimental embryology is an adjunct and not an alternative to comparative embryology."

As good an illustration of the author's preferred form of generalization as the book affords is contained in the following quotation:

"We are thus led to form the following conception of the past history of the lower Metazoa. A widespread and dominant race of blastula-like animals once swarmed in the primeval seas. Some of these took to a creeping life and eventually gave rise to the group of sponges; others kept to the free-swimming life and developed into planulae, and so gave rise to the Cœlenterata. Some of these planulae, by the specialization of the cilia into comblike locomotor organs, became Otenophora; whilst the remainder adopted a fixed life and attached themselves by their aboral poles. This change occurred in the different divisions of the stock at different stages of the evolution of the internal organs of the planula ancestor, and in this way the groups of Hydrozoa, Scyphozoa and Actinozoa arose."

One is tempted to ask are such questions really the fundamental questions of comparative embryology? No one doubts the broad fact of evolution; nor can it be questioned that embryology is a strong aid to comparative anatomy and paleontology in the investigations of relationships. But the method has its limits, which seem to be surpassed in the above citation.

The experimental method in embryology is not a mere adjunct to comparative embryology of this sort. Indeed, experimental embryology has contributed very little to the phylogenetic interpretation of ontogeny, and in the very nature of things it is impossible that it should do so.

We have in fact two quite radically distinct points of view in embryology, viz.: the comparative anatomical and phylogenetic represented by Professor MacBride, and the functional analytic. Both rest, of course, upon descriptive embryology. Experimental methods are more or less applicable to both. But whereas their use for phylogenetic purposes must be limited to relatively simple purposes, such as determination of origins of parts where purely observational method fails, and can be of no service for the more general problems of phylogeny, experimental methods contribute the essential data for functional analytic problems of embryology, and are absolutely necessary for the investigation of all the more fundamental questions.

The phylogenetic and the functional analytic points of view in embryology diverge from a common basis of observation and experiment. Experimental embryology is not merely an adjunct to comparative embryology. The broadest aspects of phylogenetic embryology must forever, so far as we can see, remain matters of opinion, which can never be subjected to crucial experimental investigation. The reaction against this type of embryological research is therefore due not merely to lack of patience, but also to lack of confidence. That there remains much important work to be done of a purely descriptive character in embryology goes without saying; it is being produced all the time; but in the best works of recent years there is a notable reserve with reference to phylogenetic speculation.

Professor MacBride has selected and limited his material according to his point of view. One result is an altogether inadequate treatment of general and also experimental embryology. In this there is no lack of consistency, and it is therefore not in itself a matter for

just criticism. But certain regrettable mistakes occur in this part of the subject: for instance on page 3 it is stated that the terms oocyte and spermatocytes of the first order are applied to the germ-cells at the end of the period of growth, whereas these names are usually applied from the beginning of this period. On p. 16 the chromosome interpretation of Mendelian phenomena is given incorrectly, but is partially corrected in a footnote; on page 17 increase of "alkalinity" of the sea water is attributed to addition of butyric acid; evidently a slip. On p. 524 Morgan is credited with the discovery of inducing artificial parthenogenesis in sea urchins by treatment with hypertonic sea-water, and Loeb stated to have confirmed this result in 1910. Loeb, of course, made the original discovery in 1899. Several other similar errors occur.

Professor MacBride's volume is to be welcomed as a useful account of descriptive invertebrate embryology. But, to complete the series in which it belongs, there is a need of a volume which shall treat the cytological, functional analytic and general problems of embryology, which seem to the writer to constitute the most significant aspects of the embryological research of the last thirty years.

F. R. L.

An Introduction to the History of Medicine, with Medical Chronology, Bibliographic Data and Test Questions. By FIELDING H. GARRISON, A.B., M.D. W. B. Saunders Company. 1914. Pp. 1-763, illustrated with numerous portraits of eminent men, to which is appended an extensive bibliography covering 18 pages.

The author, in his preface, states that "the object of this book is to furnish the medical student or the busy practitioner with a definite outline of the history of medicine . . ." But it is apparent, even on a hasty examination, that the work is capable of much wider usage and may easily be regarded as the most convenient volume of reference on the historical phases of medicine which has been issued recently in the English language. It ranks with the larger and more extensive works of Haeser

and of Neuburger, Puschmann and Pagel, though more modest in scope.

The work bears clear evidence of its author's intimate association with the best medical library of the continent and he has made free use of the extensive material in the Surgeon General's library. The volume is chiefly a biographical study of the development of modern medicine, the characters being fully portrayed or briefly mentioned as a particular phase of their career bore an impress on the period or on a certain phase of medicine. One is thus compelled to search in several places for the details of any one man, and even then he finds many only scantily given, this being in accord with the author's views of writing a history of medicine. Both the men involved and the condition of the times in which they worked united to produce the final result.

From the viewpoint of anatomy the work is especially useful. Anatomy has been given its widest application and all phases of biology bearing on the development of medicine have been discussed, with brief or extensive mention of the more eminent men who have had a part in the development of anatomy, not only as directly applied to medicine, but in the purely scientific aspects of the science. Not only is mention made of the men who have been influential in the development of anatomy, but the political conditions of the times in which they worked are discussed. Their more important discoveries are given with, in many cases, exact references to the literature where they were formally discussed; thus adding immensely to the usefulness of the volume. The titles of the more important larger works of many of the prominent anatomists of all time are given, with date and place of publication. The early writers such as Galen, Hippocrates, Fontana and others are treated with especial care and notices of their writings are accompanied by useful notes as to number of editions, translations and commentaries with a statement of which are considered the most authoritative. These notes will save the student just beginning the study of the history of anatomy many blunders and much valuable time.

A glance at the first few chapters will give an idea of the scope of the work.

The first chapter is entitled, "The Identity of all Forms of Ancient and Primitive Medicine." It is a discussion from an ethnological standpoint of what has been determined concerning the condition of medicine among primitive races of ancient and modern times, in which are found traces of modern tendencies in medicine. Chapter II. is given up to Egyptian medicine. The chapter opens with a brief discussion of the fossil remains of man leading up to a statement of the antiquity of Egyptian civilization. Our author says: "At the same time the gap between paleolithic and neolithic man is much greater than that between the people of the late Stone Age and the civilizations of Egypt and Mesopotamia." The following pages are devoted to a discussion of medicine among the Egyptian peoples from the time of the earliest known physician I-em-hetep (4500 B.C.) to the time of the predominance of Greek thought. The most important Egyptian medical documents are the papyri of Brugsch, Ebers and Hearst, the chief of these being probably the Ebers papyrus, which was discovered by Georg Ebers at Thebes in 1872 and dates back to 1550 B.C. It is interesting to note the absence of all anatomical learning in Egypt until the time of the introduction of Greek thought which resulted in the famous Alexandrian school.

Chapter III. is devoted to Sumerian and Oriental Medicine. "To sum up what we owe to Oriental Medicine, the Babylonians specialized in the matter of medical fees, the Jews originated medical jurisprudence and public hygiene and ordained a weekly day of rest, and the Hindus demonstrated that skill in operative surgery which has been a permanent possession of the Aryan race ever since."

Chapter IV. treats of Greek medicine and is divided into three sections: (1) Before Hippocrates, (2) The Classic Period (460-146 B.C.), (3) the Græco-Roman period (146 B.C.-476 A.D.). Chapter V. gives a discussion of the Byzantine period (476-732 A.D.). "Although the Byzantine power lasted over a thousand years (395-1453 A.D.) medical history

is concerned chiefly with the names of four industrious compilers (Oribasius, Aetius, Alexander of Tralles, and Paul of Aegina) who were prominent physicians in the first three centuries of its existence." Chapter VI. is devoted to the Mohammedan and Jewish periods (732-1096 A.D.). The titles of the next two chapters, "The Medieval Period" (1096-1438), "The Period of the Renaissance, the Revival of Learning and the Reformation" (1438-1600), will give an idea of the trend of the work.

In a compilation of such magnitude it is impossible that all errors should be avoided, and if attention is called here to a few errors in proof-reading it is with no thought of deduction, but with the hope of adding to the usefulness of the work. On page 24, 13th line from the top *metal work* is evidently intended, instead of mental work as it is printed; on page 184 the last year of Robert Hooke's life was 1703, instead of 1763 as printed. In the index to personal names the page reference to Carl Ferdinand von Arlt should be 549, instead of 547, McClung should be 474, instead of 592. In the index to subjects (p. 761) Sex, determination of, should read 474 instead of 592. These defects are of minor importance, but are rather annoying when one has to search for the correct page. In four weeks' almost continuous use of this volume the above errors are the only ones which have come to my notice.

ROY L. MOODIE

UNIVERSITY OF ILLINOIS,
COLLEGE OF MEDICINE,
CHICAGO.

THE NATURE AND ORIGIN OF FIORDS

THERE are two groups of geologists whose ideas regarding the origin of fiords are mutually opposed. The first group may be designated as the "glacialists," because in their opinion all the phenomena peculiar to fiords may be explained as the result of extensive glacial over-deepening of pre-glacial river valleys near the sea. The second group, or "non-glacialists," reject the theory of ice erosion, and attempt to account for the phenomena of fiords in other ways.

Members of the non-glacialist group are by no means in agreement among themselves as to the origin of fiords. They agree on one thing only,—that ice did not excavate these deeply submerged canyons. Some consider fiords the product of normal stream erosion followed by a partial submergence which permitted the valleys to be drowned. Others think that peculiar jointing of crystalline rocks enabled streams to carve peculiar valleys which were later submerged. A few even appeal to "some force not yet known to the geologist." Formerly many observers were inclined to regard every fiord as either a gaping chasm or a rift valley formed by the dropping down of a narrow strip of the earth's crust between two parallel faults. This tectonic theory of the origin of fiords, once much in vogue as an explanation for all valleys, is now generally regarded as obsolete. It is this theory which Professor J. W. Gregory defends in a spirited manner, in his recently published book on "The Nature and Origin of Fiords."¹

Gregory divides his volume of more than 500 pages into three parts. Part I. outlines the problem which fiords present to the geologist, and discusses at much length different classifications of shorelines. Perhaps most readers will feel that here the author has laid undue stress on unimportant details of classifications which are empirical at best, and would have welcomed some attempt at a classification more truly genetic than any of those considered. In Part II., comprising about two thirds of the printed text, the author describes the fiord systems of the world, with the object of proving that the fiords of each district can best be explained on the basis of the tectonic theory. With the fiords of Norway, New Zealand, and other typical fiord areas, he classes the drowned valleys of the Dalmatian coast and other submerged normal river valleys which few besides the author would regard as fiords. Part III. is in part a résumé

and amplification of the author's arguments against the glacial theory of fiord formation and in favor of the tectonic theory; and in part an elaboration of a theory of polar oscillations which might fracture the earth in such a manner as to explain the actual distribution of fiords. For in the author's opinion "the ultimate cause of fiords is the rupture of wide areas of the earth by the pulsation due to the titanic forces started by those disturbances which upheaved the existing mountain systems of the world."

The book is abundantly illustrated with sketch maps and diagrams and a limited number of excellent engraved plates. A partial bibliography of the subject of fiords covers 26 pages, while the text is filled with citations from the works of other investigators. Subject, authority and locality indexes are provided. A fairly long "errata" slip suggests inadequate proof-reading, and appears itself to stand in need of revision. Thus a reference to page 468 tells us that the sentence "The occurrence of the chief fiords and mountain-systems on the western sides of the continents is probably a consequence of the rotation of the earth from east to west," should be made to read "is probably a consequence of the rotation of the earth whereby raised areas lay from east to west." (Presumably "lay" should be changed to "lag.") But there is inserted on page 468 another erratum slip which advises us to read the sentence as follows: "The occurrence," etc., "is probably a consequence of the rotation of the earth from west to east, whereby raised areas lag." The reader may take his choice of these corrections; but after he has arranged this sentence satisfactorily his troubles are not over, since three additional corrections must be made in the two sentences which succeed it. Under such circumstances the reader may be pardoned if he is unable to discover what the author meant to say.

A word of explanation may properly precede the more detailed examination of Gregory's book. When an author of recognized ability produces a book which, however valuable, does not contain much novel material nor many

¹"The Nature and Origin of Fiords," by J. W. Gregory. John Murray, London, 1913. Pp. 452.

new interpretations, a brief summary may give a fair conception of the nature of the work. When an author of no standing advocates unusual or startling interpretations, a very short review may suffice to characterize his effort. But when a writer of good standing, profiting by personal observations over an extended field, decides to support in an elaborate treatise a theory rejected as untenable by most of his colleagues in the science, something more than passing notice is required. "The Nature and Origin of Fiords" is the most elaborate work on this subject which the reviewer can recall. In it the well-known author of "The Great Rift Valley" supports a theory which the reviewer in common with most students of land-forms regards as untenable. The reasons for not accepting Gregory's arguments and conclusions should therefore be made plain.

Gregory's book was written primarily to disprove the glacial theory and to establish the validity of the tectonic theory of fiord origin. One might anticipate, therefore, that the author would set forth in the clearest terms the essential points of each theory, and more especially the critically important points of contrast between the two. Only after such an analysis would the reader be adequately prepared to weigh the evidence for and against the theories, and to decide intelligently between them. Unfortunately, while Gregory discusses both theories repeatedly, he presents no adequate analysis of either; and only after the reader has followed with increasing perplexity through a maze of contradictory arguments does he finally discover that the author's conceptions as to what are implied by the glacial and tectonic theories often differ radically from the generally accepted views. In order that we may properly appreciate the author's treatment of this important matter, let us summarize hastily some of the essential elements of each theory.

According to the glacial theory, fiords are partially submerged glacial troughs. The troughs of glaciated mountains far from the sea are similar to fiords, except that the former have not been drowned by marine waters. In both cases the troughs were formed

by extensive glacial over-deepening of former river valleys. The preglacial valleys guided the glaciers which later came to occupy them, and by confining the ice streams to the narrow limits imposed by the valley walls insured a maximum efficiency of glacial erosion. The glacial theory asks no questions as to what determined the courses of the preglacial valleys; but it is fully recognized that among other causes ancient fault lines must be considered, since a fault may give a crushed zone which is weaker than the unfractured rock, or may bring a belt of weak rock into such position that subsequent valleys will soon be excavated along it, and hence parallel to the fault.

According to the tectonic theory, on the other hand, fiords are directly due to forces within the earth which cause a pronounced local and recent deformation of the earth's surface. This deformation may be in the nature of a gaping fissure where the rocks have parted along a fault or joint plane; or it may consist of a rift valley or graben caused by the down-dropping of a narrow strip of the earth's crust between two parallel faults. Such depressions may later be modified by river or glacial action; but the essential features of fiord topography must have existed prior to such modification. And whereas, according to the glacial theory, many fiords may be located along fault lines or joints, according to the tectonic theory *every* fiord must be so located.

Without pursuing this contrast further, let us turn again to Gregory's treatment of the problem. His misconceptions of the glacial theory are at once apparent. We have seen that this theory involves the recognition of preglacial river valleys which determined the courses of the more recent ice streams. Yet Gregory devotes a large amount of space to arguing that the valleys existed before the ice came, under the erroneous impression that this is incompatible with the glacial theory. In chapter after chapter this remarkable position is vigorously maintained. Indeed, he tells us that "The most conclusive argument against the glacial origin of the fiords is the preglacial age of their valleys; and it appears

to be admitted for practically all fiord-areas that the valleys are preglacial" (451). "The most fatal objection to the glacial origin of the fiords is the preglacial age of their valleys" (263).

It also follows from the glacial theory that the ice streams, being compelled to coincide in direction with the preglacial valleys, must often pursue courses which make large angles with the general direction of ice advance. Yet our author in combating the glacial theory lays much emphasis upon the fact that fiords are not always parallel to the general movement of the ice. "The distribution and arrangement of these Alaskan and British Columbian fiords is quite inconsistent with the theory of their glacial origin. The development of the fiords appears quite independent of the glaciation of the country; the direction of the fiords is not simply radial from the chief glacial centers" (317-18). "The direction of the ice-movement, however, did not fully agree with the trend of the fiords" (140). "Most fiord countries supply abundant instances of the fiords and the ice-movements having different directions" (451).

A still more serious misapprehension is entertained by the author as to the significance of the oft-observed coincidence between fiords and fault lines. As already noted, the glacial theory of fiord origin fully recognizes the fact that the preglacial valleys, later transformed into fiords, were often excavated along ancient fault lines. To prove the presence of a fault-line through a fiord is therefore to prove nothing as to the glacial or tectonic origin of that fiord. But Gregory is not of this opinion. A very large proportion of his argument against the glacial theory consists simply in showing that faults are associated with fiords. Indeed, he is often content to show that *some* fiords in a region are traversed by faults; or even that faults are known which trend parallel with the fiords of a given region; and on such a basis concludes in favor of the tectonic theory of fiord origin. Often he goes so far as to admit that the fiord-valley was not formed by crustal deformation, but by stream erosion along a crushed or weak rock zone;

yet he cites even such cases in support of the tectonic theory, entirely ignoring the all-important distinction between valleys produced by erosion along ancient fault lines, and depressions due to deformation along recent fault lines. The fiords of western Iceland are described as "connected with a series of fractures" (141) while "Faults are numerous around the Greenland coast, and in many cases they coincide with the fiords" (265). "The evidence for these faults (in Alaska) is often obscured, and along the fiords such faults could hardly be recognized; but their recognition by Messrs. Moffit and Capps in the Nizina district renders it probable that intersecting faults may be widely distributed through Alaska, and form planes of weakness along which the fiords have been excavated" (322-23). "The tectonic origin of the (New Zealand) fiords has been recently advocated by Speight. He accepts Andrews' view that they are old river valleys modified by glaciation, but he recognizes that the original course of the valleys was dependent on lines of fracture in the earth's crust" (365). The most pronounced glacialist would accept much of Gregory's lengthy argument against the glacial theory, as a statement of conditions normally to be expected on the basis of that theory.

A careful study of the author's ideas concerning tectonic valleys in the hope of finding some explanation for the apparent lack of consistency in his arguments, only increases one's perplexity. On page 394 we read: "Some valley systems are due to the folding of the earth's crust, which has raised soft bands to the surface, where they are worn into valleys, while the harder rocks resist and remain as ridges. The faulting of the earth's crust also produces bands of weak and shattered rocks which are easily washed away, and thus many valleys have been worn out along fault lines. Joints have a somewhat similar effect. . . . Such valleys, though their directions have been determined by earth movements, are valleys of excavation. Tectonic valleys, on the other hand, are the direct results of the earth-movements themselves." This is a clear

statement of the generally accepted distinction between erosion valleys guided by structure, and tectonic valleys; but it is directly contradicted by the major portion of the author's arguments on the preceding 300 pages of the book. The contradiction is even more amazing when we compare this statement with one on page 455, where tectonic valleys are divided into several groups and one group is defined as follows: "Valleys formed along fault-planes owing to the removal by denudation of a belt of rocks which has been crushed by earth-movements." It is clear that the author's ideas as to what constitutes a tectonic valley, the most vital point in his entire book, were confused and contradictory, and varied from time to time as he wrote. Similar contradictions regarding other matters appear so frequently throughout the book that it is often quite impossible to know what opinion the author really holds regarding essential points in the problem he discusses.

Throughout the book much reliance is placed on *authority*, and hundreds of quotations favorable to the tectonic theory are adduced to strengthen the case for that theory. Many of these quotations date back to a time when the knowledge of land forms was in its infancy; others are from writers unqualified to speak authoritatively on the interpretation of land forms; and occasionally the author quoted wrote in a poetic or figurative sense. In the chapter on Alaskan fiords Gregory writes: "The explanation of these fiords as simply due to glacier corrosion seems to me quite inadequate. That they are due to the action of some tectonic force has been recognized by many visitors to them. Mr. John Burroughs has graphically expressed this view." Then follows this quotation from Mr. Burroughs: "The edge of this part of the continent for a thousand miles has been broken into fragments, small and great, as by the stroke of some earth-cracking hammer, and into the openings and channels thus formed the sea flows freely, often at a depth of from one to two thousand feet." The fact that Mr. Burroughs is not a geologist, and is therefore presumably unacquainted with

Alaskan geology, did not deter Gregory from citing this bit of imagery as a substantial confirmation of his theory. Views unfavorable to the tectonic theory are also quoted at length, but are quickly dismissed as untenable. Favorable views are as quickly accepted. In neither case is there any serious attempt to present the quoted author's evidence, review his line of argument, and then subject his conclusions to critical analysis before accepting or rejecting them.

Another reason for accepting Gregory's work with reserve is found in his frequent misinterpretation of the views entertained by authors from whom he quotes. His own belief in the tectonic theory was so strong that he unconsciously read into the works of others ideas favorable to his theory which they did not express. Of the many instances of this I will cite but a few. On page 309 Gregory refers to the work of Tarr and Martin on the Yakutat Bay earthquake, and while he acknowledges that these authors recognized but one fault along Russell fiord, and attributed the present depth and form of the fiord to glacial erosion, he goes on to say that "the shores of this fiord appear to lie along two old faults, the prolongation of which formed the valley occupied by the Hidden Glacier, and movements along the two faults would explain the facts as well as along one fault. This earthquake illustrates how fiord valleys have been formed by parallel trough-faults. . . . Tarr and Martin's memoir shows that the formation of fiord-valleys by trough faulting is still in progress in Alaska." After reading this, one unfamiliar with the memoir in question will be surprised to find that Tarr and Martin considered the faulting hypothesis of origin for these fiords at length, adduced a variety of evidence opposed to this theory, and concluded by showing that it was quite impossible to explain the fiords as a product of faulting. According to Martin the stratigraphic evidence positively proves the absence of two parallel faults. In support of his position Gregory says that in a later memoir Tarr "attached less importance to glacial action" in the formation of fiords.

On the contrary, the memoir cited is a most vigorous argument in favor of the glacial theory of fiord formation. In it Tarr writes: "Of all the hypotheses proposed, glacial erosion alone appears capable of explaining all the facts. . . . The facts set forth in this chapter prove conclusively that ice has eroded in this inlet to a remarkable degree. . . . Those who oppose vigorous glacial erosion are in the position of those who opposed river erosion long after the majority of workers accepted it—that of ultra-conservatism."²

Gregory cites Mendenhall's discussion of differential warping in the Cook Inlet region of Alaska, and continues: "These two fiords, therefore, according to Mendenhall, occur along a depression due to earth-movements, and the same explanation offers the simplest interpretation of many other Alaskan fiords and fiord-straits. They appear to be of tectonic rather than of glacial origin" (324). But Mendenhall's report conveys a very different idea.³ He shows that normal river valleys were occupied by glaciers which "greatly modified" them, and that then these glacially modified valleys were submerged by a depression of the land. Only later, after the fiords had already been in existence for some time, began the differential warping cited by Gregory. As this was an unequal uplift, it tended to *destroy* fiords by raising them above the sea-level, not to make them. It is difficult to understand how even an enthusiast for the tectonic theory could find in this faint differential uplift an argument for the tectonic origin of the deep-cut Alaskan fiords. The same might be said of the author's appeal to the differential uplift of the Labrador Coast, as described by Daly, as an explanation for the rock basins and thresholds of Labrador fiords (283); for it is impossible to see how the slight warping of a little more than one foot per mile described by Daly, could account for the re-

versed slopes of more than 250 feet per mile in the fiords.

Spurr is also quoted in support of the tectonic origin of Alaskan fiords. Gregory writes: "According to Spurr the lake-basins are preglacial. He says that 'all the lakes of southwestern Alaska, so far as observed by the writer, occupy mountain-valleys which are evidently the ancient river-valleys of the late Miocene'" (319). This quotation from Spurr says nothing at all about the preglacial age of the lake basins. The preglacial age of the valleys alone is indicated; and the context from which this quotation was taken makes it quite clear that the lakes, and consequently their basins, are of more recent date.⁴

Gregory's interpretations of his field observations do not always carry conviction. Photographs and sketches of typical glacial troughs with well-developed catenary curves are described as "V-shaped valleys" and "normal denudation curves," apparently because slight bendings of a trough cause the distant profile of one trough wall to intersect the foreground of the opposite wall (Plate V., Figs. 73d, 73e). It is truly remarkable that such a drawing as Fig. 73d could be cited by any one as a "V-shaped valley"; but even more remarkable is the author's attempt to show that the well-known contrast between the forms of glaciated and non-glaciated valleys does not exist (425-32). Although the author has traveled widely, he "can not remember to have seen any considerable mountain-chain or mountain-area in any non-glaciated district which does not show truncated spurs, spurless walls and hanging valleys" (447). The supposed tectonic origin of Cattaro Bay, one of the Dalmatian "fiords," is illustrated by a beautiful photograph of the bay, in which what appear to be triangular "flat-irons" or hogbacks formed by resistant layers in the folded beds, are described as "triangular facets due to faulting" (Plate VI.).

Many readers will hesitate to accept Gregory's arguments because of the significant

²R. S. Tarr, "The Yakutat Bay Region, Alaska," U. S. G. S., Professional Paper 64, p. 118, 1909.

³W. C. Mendenhall, "A Reconnaissance from Resurrection Bay to the Tana River, Alaska, in 1898," U. S. G. S., 20th Annual Report, Pt. VII., 332-34, 1900.

⁴J. E. Spurr, "A Reconnaissance in Southwestern Alaska in 1898," U. S. G. S., 20th Ann. Rept., Pt. VII., p. 258, 1900.

omissions which characterize the text. Against many of the arguments made by the author, other writers had previously raised very serious objections. We look in vain for any answer to many of these objections, or even mention of them. In the chapter on Dalmatian fiords, there is no intimation of the fact that a normally dissected belt of folded mountains, partially submerged (which is the type of topography found in this region) will necessarily have the long, narrow bays, the steep sided, spurless valley walls, and the short cross-valleys which the author erroneously correlates with those features in fiord districts often described in the same terms, but which really present a distinctly different topographic aspect. The fact noted by the author (202) that one of these drowned valleys has been called a "fiord" in Baedeker's guide book, can not be regarded as very significant. In support of the tectonic theory the author states that the Dalmatian valleys are not arranged like the members of ordinary river systems, as in Dalmatia the branchings and bendings are usually rectangular (207). He does not recognize that in all folded mountain regions involving rock layers of different resistance, the ordinary river valleys normally have this rectangular or "trellised" pattern. His arguments for the tectonic origin of the submerged Dalmatian valleys would apply with precisely as much force to the valleys of the folded Appalachians, the Juras and other similar dissected folds. The short cross valleys are not recognized as a normal product of river erosion across a narrow ridge of hard rock, but are interpreted in accordance with that ancient theory, long ago abandoned by most geologists, which explained the cross valleys as short cracks formed by bending brittle material. The substantial reasons which led geologists to abandon this theory as untenable are not referred to by the author.

It would be easy to multiply indefinitely examples of the unsound reasoning which seems to the reviewer to deprive the book before us of most of its value. The instances I have cited are not isolated examples which

might be explained as the result of careless writing, but are typical of the book, as a whole, and must fairly represent the author's mental attitude toward the problem of fiord formation. It seems to the reviewer, therefore, that Gregory's attempt to rehabilitate a discarded theory of fiord formation must be considered a failure.

DOUGLAS W. JOHNSON

SPECIAL ARTICLES

THE IMPORTANCE OF A CONSIDERATION OF THE FIBER PROTEINS IN THE PROCESS OF BLEACHING COTTON

THE nitrogen which is found in the ripe cotton fiber seems to have some bearing upon the yellowing of bleached cotton cloth, as was pointed out by J. C. Hebden in his paper read in Troy before the American Institute of Chemical Engineers.¹ He showed that in the process of bleaching cotton cloth after the first caustic boil 91.5 per cent. of the proteins were removed from the fiber, whereas of the fats and waxes only 20.4 per cent. were removed; and after the second caustic boil 91.7 per cent. of the proteins and only 64 per cent. of the fats and waxes were eliminated; the "chemick" and the "sour" together, he showed, removed 12.05 per cent. of the remaining protein impurities and 10.23 per cent. of the remaining fats and waxes. According to his analysis, after all the bleaching operations there were still left on the fiber 30.4 per cent. of the total fatty and waxy impurities, whereas of the total proteins there were left only 7.3 per cent., and as the cloth which he analyzed had undergone a "good bleach," he felt safe in inferring that it is the failure to remove the protein impurities from the cotton that results in a "bad bleach" or causes the yellowing of cloth in steaming or during storage.

So far as we know, the investigator above referred to was the first to point out the possibility that the proteins of the fiber played such a part in the bleaching of the cloth. Previous to this it has been believed that the fatty and waxy matters and especially the

¹ *Journal of Industrial and Engineering Chemistry*, September, 1914, Volume 6, No. 9, page 714.

pectins were chiefly responsible for the yellowing of the fiber, since they formed water insoluble compounds, which remained on the fiber. The analysis of Hebden, however, showed that the calcium fixed on the fiber in the form of calcium salts was decomposed by the following acid treatments, and he explained the presence of the calcium on the fiber after the sour by the formation of a calcium cellulose similar to that of soda cellulose. The possibility of the formation of such a cellulose, he believed, was supported by the fact that cotton cloth which has been boiled and bleached did not produce as clear and as brilliant a turkey-red as cloth which had been simply boiled, because the former was not in a condition to fix calcium.

As the result of investigation in this line on cloth from different bleacheries, it occurred to us that an analysis of the growing cotton fiber with a view of determining the nitrogen and the fat and wax factors might reveal some points of importance. The determinations were carried out on Durango cotton raised on the United States Experiment Farm, San Antonio, Texas.*

The nitrogen factors were determined by the Kjeldhal-Gunning method, and the fat and wax factors by extracting samples of the fibers first by ether and then by alcohol. Some of the experiments were carried out in duplicates and some in triplicates, and the averages of the determinations were recorded as the final results. The figures given in the table below can only be regarded as approximating the absolute values of the nitrogenous and fatty and waxy constituents of the fiber; for the determination of exact values a much larger number of experiments should be performed. Nevertheless, they show the tendencies of the two factors and have, therefore, significance. The nitrogen determinations were made and recorded beginnings from the 14-16-day stage up to the 36-38-day stage, whereas the ether and the alcohol extracts were recorded only beginning with the 22-24-day stage, because

* We wish to thank Mr. Rowland D. Mead, of the United States Department of Agriculture, for supplying us with the necessary samples of the cotton fibers.

in the stages previous to this the amount of tannins extracted by both ether and alcohol were much higher than the fats and waxes.

Age in Days from Flowering	Nitrogen in Per Cent.	Protein N. \times 6.25	Alcohol Extr. in Per Cent.	Ether Extr. in Per Cent.	Fat and Wax in Per Cent.
14-16	2.2300	13.938
16-18	1.9480	12.175
18-20	1.4250	8.907
20-22	1.1820	7.388
22-24	4.405	2.819	7.225
24-26	.3760	2.350	1.745	.775	2.418
26-28	.3185	1.997	1.308	.713	2.111
28-30	.3123	1.952	1.418	.800	2.215
30-32	.2657	1.661	1.522	.702	2.304
32-34	.2590	1.619	1.522	.789	2.245
34-36	.2503	1.564	1.403	.802	2.205
36-38	.1815	1.134	1.409	.791	2.200

From the above table it may be seen that the fats and waxes showed neither a gradual increase nor a gradual decrease in their percentages, and in view of the fact that the fiber was growing, it seems reasonable to suppose that the fatty and waxy substances increased proportionally as did the fiber. We believe that were the numbers of the experiments large enough to give averages approximating the absolute values of the fatty and waxy factors, this point would have been brought out much clearer. But even from the determinations which we can report, it appears that the fats and waxes extended in an even and constant thickness over the fiber. If we accept the view that the function of these substances is to protect the fiber from external influences of weather and disease, that is that they are merely external coats of the fiber, the significance of such a proportional growth of these constituents becomes clear. If, however, the fats and waxes are phosphatides taking part in the growth, there would also be a proportional increase. The nitrogen figures, on the other hand, show gradual decrease in percentage with the increase of the age of the fiber. The sudden increase of the factor at the 20-22-day stage as compared with that of the 24-26-day stage may be due either to a rapid growth of the nitrogenous constituents of the fiber or to the adhering nitrogenous coloring matters of the parts of the boll which surrounded the

fibers. If we limit ourselves to a consideration of the nitrogen figures of the samples representing only the higher stages of development of the cotton fiber even then we are permitted to assume that the nitrogen was deposited early in the lumen of the fiber and its absolute value remained constant. This assumption becomes more plausible when the nitrogen figures are multiplied by 6.25 to express the percentage of proteins present in the fiber. Most of this early and constant protein deposit remains in the lumen in the form of insoluble albuminoids and in the form of alcohol soluble proteins; some of it is utilized by the growing fiber, probably by the spiral forming the walls of the lumen. That the proteins of the fiber are of an insoluble nature is shown by the fact that the percentage of nitrogen of gray cloth as obtained by Hebden (0.191 per cent.) remained practically unchanged after the "steep" (0.192 per cent.), and that some of it exists in the fiber in the form of alcohol soluble proteins, is shown by the number which he obtained for nitrogen after extracting the cloth by ether and alcohol. The percentage, as shown in his table, was reduced from 0.191 per cent. to 0.161 per cent. The fact that the first caustic boil removed 91.5 per cent. of the protein content clearly points to the decomposing action of boiling alkali upon the albuminoids.

The 7.3 per cent. of total protein content remaining in the fiber after all the operations of the bleaching process can be considered as that part of the fiber proteins which has become an inseparable part of the wall of the lumen. The lowest percentage for fats and waxes (2.200 per cent.) obtained by us for the fiber taken directly from the field was considerable higher than that obtained by Hebden for fibers which were ginned, carded, spun and woven (1.405 per cent.). The removal of a large part of the fats and waxes by mechanical means during ginning, carding, spinning and weaving proves that these constituents form the outside cover of the fiber, and it is reasonable to suppose, therefore, that they do not play as important a part in bleaching as is ascribed to them. The percentage of nitrogen in our experiment (0.1815 per cent.) was some-

what smaller than that obtained by Hebden for cotton in the form of cloth (0.191 per cent.) and points to the fact that, unlike the fats and waxes, the proteins of the fiber are not adventitious nor coating factors, but that they are within the lumen or are in part intimately bound to the fiber. As the proteins are of the insoluble kind, the above seems to justify the assumption of Hebden that in bleaching the removal of the proteins may be of more importance than that of the fats and waxes.

These results and the results of Hebden show the necessity of a careful investigation of the chemical nature of the fatty and waxy substance as well as of a further study of the effect of growth on these constituents of the cotton fiber.

THE AMERICAN PHYTOPATHOLOGICAL SOCIETY

THE sixth annual meeting of the American Phytopathological Society was held in the medical building of the University of Pennsylvania, Philadelphia, Pennsylvania, December 29, 1914, to January 1, 1915. About 95 members were present; 7 new members were elected, making a total of 293. The following officers were elected for 1915:

President—H. H. Whetzel.

Vice-president—W. A. Orton.

Councillor—Mel. T. Cook.

Donald Reddick was elected editor for three years and made chairman of the board. The following associate editors were elected for three years: H. W. Barre, E. A. Bessey, H. R. Fulton, W. T. Horne.

C. L. Shear was elected business manager vice Donald Reddick.

The society decided to hold its next annual meeting at Columbus, Ohio, in connection with the American Association for the Advancement of Science.

A special meeting is to be held at San Francisco, August 2 to 7.

The committee on common names of plant diseases submitted a report which was ordered distributed to the members of the society for suggestion and criticism.

The society instructed the secretary to select two other persons, as required by law, and proceed to incorporate the society under the laws of the District of Columbia.

The society received greetings by telegraph from the newly organized Western Branch meeting at Corvallis, Oregon. The following resolution was adopted by the society:

"The council recommends that the society extend cordial greetings to the newly organized Western Branch of the American Phytopathological Society, and also recommends that a committee consisting of the present president, Haven Metcalf, and the secretary, with power to increase their number to five, be authorized to formulate the necessary terms of affiliation to provide for this and other future branches which may be organized."

The following constitutional amendment proposed at the last meeting was adopted:

Article 3, section 3, shall be changed to read: "Any person may become a patron upon the payment of \$100."

The method of presenting papers by abstract introduced at the Atlanta meeting was continued, with slight modifications, with much success. Six minutes were allowed for the presentation of each paper, the author being permitted to read the abstract as printed, or use the allotted time in giving additional explanations or presentation of the topic, after which five minutes were allowed for discussion. The same method of handling the program was adopted for the future and the secretary authorized to limit the time for the acceptance of titles and abstracts to December 1, in order that they might be published in the December issue of *Phytopathology*.

The following resolution in regard to the *Uromyces* disease of alfalfa was adopted:

WHEREAS, The plant pathologists or other officials of the individual states are unable properly to meet the situation, partly from lack of information, partly because it is essentially an international and interstate problem, be it therefore

Resolved, That we respectfully invite the attention of the Honorable Secretary of Agriculture and other officials of the U. S. Department of Agriculture to the above facts and urge the importance of immediate earnest investigation under their leadership as to the present occurrence and seriousness of the disease, as to its means of distribution and as to what steps, if any, should be taken to check its further spread.

The society passed a unanimous vote of thanks to the local committee for the excellent facilities and courtesies offered the society during the meeting, and to Dr. F. D. Heald for the care of the exhibits

and other assistance in promoting the success of the meeting; also to the chair for conducting the meeting with promptness and carrying the program through on time.

The following program of 58 papers was presented:

Tuesday, Joint Session with Section G, American Association

Meeting of the council and board of editors, Hotel Walton.

December 30, 1914

"The Verticillium Wilt Problem," by C. W. Carpenter.

"Orchard Experiments in 1914," by Mel. T. Cook and G. W. Martin.

"A Nursery Disease of the Peach," by Mel. T. Cook and C. A. Schwarze.

"A Method for Excluding Mites from Pure Cultures," by C. W. Carpenter.

"Studies of the genus *Phytophthora*," by J. Rosenbaum.

"A Bacterial Leaf Spot Disease of Celery," by Ivan C. Jagger.

"The Spindling Sprout Disease of Potatoes," by F. C. Stewart.

"Thrombotic Disease of Maple," by W. H. Rankin.

"Mutation in *Phyllosticta*," by C. Harvey Crabb.

"A Nectria Parasitic on Norway Maple," by Mel. T. Cook.

"An Unreported Fungus on the Oak," by C. A. Schwarze.

"The Use of Sulphur for the Control of Potato Scab," by H. Clay Lint.

"Citrus Canker," by A. B. Massey.

"The Citrus Canker Situation," by R. Kent Beattie.

Meeting with the Botanical Society of America

Symposium: Genetic relationship of organisms.

December 31, 1914

"Leaf-spot and Some Fruit Rots of Peanut," by Frederick A. Wolf.

"Hosts of Brown-rot *Sclerotinia*," by J. B. S. Norton.

"Resistance to *Cladosporium fulvum* in Tomato Varieties," by J. B. S. Norton.

"Loss from Mosaic Disease of Tomato," by J. B. S. Norton.

"Notes on Soil Disinfection," by Carl Hartley.

"A Wilt Disease of Japanese and Hybrid Plums," by B. B. Higgins.

"The Perfect Stage of *Phyllosticta paviae* Desm.," by V. B. Stewart.

"Studies on *Plasmopora viticola*," by C. T. Gregory.

"A New Rust of Economic Importance on the Cultivated Snapdragon," by Geo. L. Peltier and C. C. Rees.

"The Relation between *Puccinia graminis* and

"Host Plants Immune to its Attack," by E. C. Stakman.

"Further Studies on the Spread and Control of Hop Mildew," by F. M. Blodgett.

"The Longevity of Pycnospores and Ascospores of *Endothia parasitica* under artificial conditions," by F. D. Heald and R. A. Studhalter.

"Field Studies of Apple Rust," by N. J. Giddings and Anthony Berg.

"Cotyledon Infection of Cabbage Seedlings by the Bacterial Black Rot," by Charles Drechsler.

"Fungus Host Relationship in Black Knot" (with lantern), by E. M. Gilbert.

"Stigmonose: A Disease of Fruits," by M. B. Waite.

"Jonathan Spot, Bitter Pit and Stigmonose" (with lantern), by Charles Brooks and D. F. Fisher.

"The Organization of the Plant Disease Survey," by R. Kent Beattie.

"Some Technical Aids for the Anatomical Study of Decaying Wood" (with lantern), by E. W. Sinnott and I. W. Bailey.

"Apple Rots" (with lantern), by Charles Brooks, D. F. Fisher and J. S. Cooley.

"The Relation of Temperature to the Infection of Cabbage by *Fusarium conglutinans* Wollenw.," by J. C. Gilman.

"Third Progress Report on *Fusarium Resistant Cabbage*" (with lantern), by L. R. Jones.

"York Spot and York Skin Crack" (with lantern), by H. S. Reed.

"Soil Stain and Fox, Two Little-known Diseases of the Sweet Potato" (with lantern), by J. J. Taubenhaus.

"*Rhizoctonia* in America" (with lantern), by Geo. L. Peltier.

"Lightning Injury to Cotton and Potato Plants," by L. R. Jones and W. W. Gilbert.

"Orchard Experiment with Jonathan Spot Rot in 1914," by G. W. Martin.

"The Perfect Stage of the Fungus of Raspberry Anthracnose," by W. H. Burkholder.

January 1, 1915, Business Meeting

"Parasitism, Biology and Cytology of *Eoconartium typhuloides* Atk.," by Harry M. Fitzpatrick.

"Negative Heliotropism of the Urediniospore Germ Tubes of *Puccinia rhamni*," by F. D. Fromme.

"The Ascigerous Stage of *Helminthosporium teres* Sacc.," by A. G. Johnson.

"A Gymnosporangium with Repeating Spores," by J. C. Arthur.

"A Preliminary Report on Twig and Leaf Infection of the Peach by Means of Inoculations with *Cladosporium carpophilum* Thüm.," by G. W. Keitt.

"Notes on *Cronartium comptoniae* and *C. ribicola*," by Perley Spaulding.

"How to Know the Polypores," by W. A. Merrill.

"Some Problems of Plant Pathology in Reference to Transportation," by F. L. Stevens.

"A Disease of Red Clover and Alsike Clover Caused by a New Species of *Colletotrichum*," by P. J. O'Gara.

"An Anthracnose of *Asclepias speciosa* Caused by a New Species of *Colletotrichum*," by P. J. O'Gara.

"A Disease of the Underground Stems of Irish Potato Caused by a New Species of *Colletotrichum*," by P. J. O'Gara.

C. L. SHEAR,
Secretary-Treasurer

THE PHILADELPHIA MEETING OF THE AMERICAN PSYCHOLOGICAL ASSOCIATION

THE twenty-third annual meeting of the American Psychological Association was held on December 29, 30 and 31, 1914, in affiliation with the American Association for the Advancement of Science and the Southern Society for Philosophy and Psychology at the University of Pennsylvania, Philadelphia. Professor Robert Sessions Woodworth, of Columbia University, presided.

As president of the association for the ensuing year, Professor John B. Watson, of the Johns Hopkins University, was selected. As members of the council, to succeed Professors Max Meyer and Margaret F. Washburn, Professors Roswell P. Angier, of Yale University, and Walter Dill Scott, of Northwestern University, were chosen. The association's representative upon the council of the American Association for the Advancement of Science will be Dr. Thomas H. Haines, of Columbus, Ohio.

It was decided to hold a special meeting for the reading of papers at San Francisco, in affiliation with the American Association for the Advancement of Science. The dates of this meeting will fall within the time selected by the larger association, August 2-7, 1915. The organization of this special meeting, and all arrangements pertaining to the program, etc., was left in the hands of a committee appointed by the president. This committee consists of Professor G. M. Stratton, University of California, chairman, and Professors Lillian J. Martin and Warner Brown. The place of the twenty-fourth annual meeting, to be held as usual during Convocation Week of 1915, was left

to the decision of the Council, and will be determined shortly.

A special feature of the business session which aroused much interest and discussion was the report of the Committee on the Academic Status of Psychology. This committee, made up of Professor H. C. Warren, Princeton University, chairman, and Professors John Dewey and Charles H. Judd, presented a comprehensive report in printed form, based upon data secured from 165 colleges and universities. The results indicated, among other things, that psychology is still constrained in many institutions to furnish the foundation for work in philosophy and education, and thus lacks the autonomy requisite in developing its own special interests and problems. Three resolutions offered by the committee were adopted by the association: (1) That a standing committee be appointed to continue the work here begun. (2) That a topic bearing upon the teaching of psychology be chosen for discussion at the next annual meeting. (3) That the association adopt the principle that the undergraduate psychological curriculum in every college or university great or small, should be planned from the standpoint of psychology, and in accordance with psychological ideals, rather than to fit the needs and meet the demands of some other branch of learning.

The program of the association included the reading of some forty-five papers. Joint sessions were held with Section L of the American Association for the Advancement of Science, and with the Southern Society for Philosophy and Psychology. As a whole, the program was notable for the evident interest of the participants in the pursuit of introspective psychology under experimental conditions. The keynote was struck by President Woodworth in his address, "A Revision of Imageless Thought," in the course of which an interesting theory of "mental reaction" was propounded to account for certain non-sensory contents of consciousness as revealed by introspective studies. Another feature was the discussion with demonstration of the introspective method, as conducted by Professor J. W. Baird, of Clark University, with the assistance of several of his former students and colleagues.

The papers read were as follows:

"Habit Formation and Modern Language Teaching," by Stuart H. Rows.

"Initial Speed and Total Gain in Learning," by E. A. Kirkpatrick.

"Notes on Certain Phases of Learning," by S. S. Colvix.

"Some Learning Curves," by M. E. Haggerty.

"Some Norms of College Freshmen," by W. V. Bingham.

"A Study in Mental Retardation in Relation to Etiology," by Bird T. Baldwin.

"A Method for Qualitative Study of Family Likeness in Arithmetical Abilities," by Margaret V. Cobb.

"Effect of Heat, Humidity and Stagnancy of Air upon Mental Work," by E. L. Thorndike.

"Notes on Affective Physiology," by George V. N. Dearborn.

"Variations in Distribution of the Motor Centers of the Monkey Brain," by S. I. Franz.

"Some Relations of Mania to the Sensorium," by E. E. Southard.

"Some Cases of Paramnesia," by Nathan A. Harvey.

R. M. OGDEN,
Secretary

THE ILLINOIS ACADEMY OF SCIENCE

THE eighth annual meeting of the Illinois Academy of Science was held at the State Museum, Springfield, February 19 and 20. The Friday afternoon program consisted of four addresses: "The Chemistry of Colloids," Dr. D. A. MacInnes, University of Illinois; "Colloids in Physiology," Dr. William Crocker, University of Chicago; "Colloids in Commerce" (read by title), Dr. L. I. Shaw, Northwestern University; "Recent Developments in Surgery," Dr. Don W. Deal, Springfield.

In the evening the members of the academy were the guests of the Springfield Commercial Association at a banquet served at the Leland Hotel. Ex-Governor Northcott acted as toastmaster, and short addresses were made by Senator Kelly and Professor John M. Coulter.

The evening lecture was delivered by Dr. Day, director of the Carnegie Geophysical Laboratory, Washington, D. C., on "Volcanic Emanations."

The Saturday morning program included the following papers:

Section of Botany, Bacteriology and Chemistry
"Character of Water Used on Railway Trains," by Dr. Edward Bartow, University of Illinois.

"Comparison of Rocky Mountain Grassland with the Prairie of Illinois," by Dr. George D. Fuller.

"Studies in *Phyllosticta* and *Ceroaspora*," by Miss Esther Young.

"The Arsenic Content of Filter Alum Used in Illinois Water Purification Plants," by Mr. A. N. Bennett.

"Method of Determining the Life Duration of Seeds," by Mr. James F. Groves.

"Studies on *Schizophyllum dincum* in Respect to Cultures and Inoculations," by Mr. Alvah Peterson, University of Illinois.

"The Longevity of *B. Cok* and *B. Typhorus* in Water," by Mr. M. E. Hinds.

"Peculiar Examples of Plant Distribution," by Dr. H. S. Pepon.

"Manganese in Illinois Water Supplies," by Mr. H. P. Corson.

"Some Features in the Classification of *Sep-toria* and *Parodiella*," by Mr. Philip Garman.

"Comparison of Methods of Determining Dissolved Oxygen in Water and Sewage," by Mr. F. W. Mohlman.

"The Grasses of Illinois," by Miss Edna Mosher.

"A Florida Smut in Illinois," by Miss Margaret Mehlkof.

"The Violets of Illinois," by Mr. Rufus Crane. *Section of Zoology, Entomology and Geology*

"What California is Doing in the Control of Injurious Insects," by Miss Gertrude A. Bacon.

"The Labium of the Nymphs of Zygoptera," by Mr. Philip Garman.

"The Comparative Morphology of Some Carabid Larvæ," by Mr. Clyde C. Hamilton.

"The Loess in Illinois: Its Age and Origin," by Dr. T. E. Savage.

"Recent Crustal Movements in the Great Lakes Region," by Professor Charles E. Decker.

"A Restudy of Worthen's Type Section of the 'Productive Coal Measures' for Central and Western Illinois," by Dr. T. E. Savage.

"The Prothonotary Warbler," by Dr. W. S. Strode.

"Some Adaptations for Respiration in Aquatic Hemiptera," by Miss Anna G. Newell.

"Mouth Parts of the Blow-fly," by Mr. Alvah Peterson.

"Collecting Snail Shells," by Mr. James H. Ferris.

"The Morphology of Certain Sphinx Pupæ," by Miss Edna Mosher.

On Saturday afternoon addresses were delivered by Ex-Governor Northcott, and the retiring president, Dr. A. R. Crook, on "The Relation of Academies of Science to the State."

The officers elected for the coming year are:

President—Dr. U. S. Grant, Northwestern University, Evanston.

Vice-president—Dr. E. W. Washburn, University of Illinois, Urbana.

Secretary—Dr. A. R. Crook, State Museum, Springfield.

Treasurer—Dr. H. S. Pepon, Lake View High School, Chicago.

The 1916 meeting will be held at the University of Illinois. E. N. TRANSEAU,

Secretary

SOCIETIES AND ACADEMIES

THE BOTANICAL SOCIETY OF WASHINGTON

THE one hundred and second regular meeting of the Botanical Society of Washington was held in the Assembly Hall of the Cosmos Club at 8 P.M., on Tuesday, February 2, 1915. Fifty-two members and six guests were present. Dr. P. A. Yoder and Messrs. Stephen Anthony and James M. Shull were elected to membership. The following scientific program was presented:

Bamboo Possibilities in America: Mr. S. C. STUNTZ.

After a brief introductory statement outlining the past history of bamboo introduction into the United States, and sketching the present condition of bamboo planting in this country, attention was directed to the possible future uses for bamboo. Furniture, basketry, especially for parcel post shipments, Venetian blinds and barrel hoops were suggested as probable industries in which bamboo would find use, while the development for ornamental planting and as a possible stock for paper was especially emphasized. Lantern slides of bamboo plantations and uses abroad and in the United States were shown, together with a considerable exhibit of manufactured bamboo articles.

Botany of Cacao and Patasthe: Mr. O. F. COOK.

The patasthe tree is a relative of the cacao, known to botanists under the name *Theobroma bicolor* Humboldt and Bonpland. It has dimorphic branches like cacao, the lateral branches being formed in whorls at the ends of the upright shoots, but only 3 laterals in a whorl, instead of 5 or 6, as in cacao. Many other differences in leaves, inflorescences and flowers were shown. The inflorescences of patasthe are confined to new growth at the ends of the lateral branches, while cacao is caulocarpous, with all of the flowers produced from the old wood on the trunk and larger limbs of the tree. The various features were explained with lantern-slide illustrations, and the paper was followed by a brief discussion of the question whether trees with such numerous and definite differences should be classified in the same genus.

Rediscovery of Lignum nephriticum: Mr. W. E. SAFFORD.

Lignum nephriticum is a remarkable Mexican wood which was celebrated throughout Europe in the sixteenth, seventeenth and the early part of the eighteenth centuries, not only for its reputed

medicinal properties, but on account of the wonderful fluorescence of its infusion in spring water. Scarcely a fragment of this wood is now to be found in drug collections, and its very name has disappeared from encyclopedias. It is celebrated as the substance with which the Hon. Robert Boyle made his first investigations in the phenomenon of fluorescence. After giving a history of the literature on the subject Mr. Safford called attention to the confusion surrounding the origin of the wood, and the causes which prevented its botanical identification. For the first time specimens of the wood accompanied by herbarium material of the plant from which it was obtained have been the subject of critical study. The heartwood produced the characteristic fluorescence described by Robert Boyle, and the botanical material corresponded with the original description of Hernandez of the plant yielding *lignum nephriticum*. This proves to be *Eysenhardtia polystachya* (Ortega) Sargent (*Viborquia polystachya* Ortega, *Eysenhardtia amorphoides* H. B. K.). The lecture was illustrated by lantern slides, specimens of the wood and botanical material, photographic enlargements of sections of the wood made by Dr. Albert Mann, plant morphologist; and also by exhibition of the fluorescence of the extract of the wood in the rays of an arc light by Dr. Lyman J. Briggs, Biophysicist, Bureau of Plant Industry, with remarks as to the value of *lignum nephriticum* as an indicator in titrimetric determinations.

THE one hundred and third regular meeting of the Botanical Society of Washington was held in the Crystal Dining Room of the New Ebbitt Hotel, at 6:45 P.M., Tuesday, March 2, 1915. Eighty-two members and seventy-eight guests were present, this being the regular annual open meeting for the president's address.

A dinner preceded the scientific program.

The retiring president, Dr. C. L. Shear, gave an address on "Mycology in Relation to Phytopathology." This appears in full elsewhere in SCIENCE.

Dr. A. S. Hitchcock presented to the society the plans for a proposed publication of a local flora on the flowering plants and higher cryptogams of Washington and the vicinity. It is proposed that this be published about one year from the present time.

The society also passed resolutions of regret upon the death of Dr. Charles E. Bessey.

PRELEY SPAULDING,
Corresponding Secretary

BIOLOGICAL SOCIETY OF WASHINGTON

THE 535th meeting of the society was held in the Assembly Hall of the Cosmos Club, Saturday, February 6, 1915, called to order by Vice-president Hopkins at 8 P.M., with 35 persons present.

Under heading Book Notices, Dr. Ransom called attention to a new biological journal under editorship of Professor Ward, of the University of Illinois, to be devoted to animal parasites.

Under heading Brief Notes, Treasurer Cooke read a letter from Dr. B. W. Evermann, now of San Francisco, a former president of the society, expressing his regret at not being able to attend meetings, his deep interest in the society, and wishes for its continued prosperity.

The first paper of the regular program was by Dr. T. Wayland Vaughan, "Remarks on the Rate of Growth of Stony Corals." Dr. Vaughan reviewed the work done by previous investigators and gave result of his own carefully conducted experiments at Tortugas. The paper was fully illustrated by lantern slides showing apparatus and methods employed in planting corals and results of one and of several years' growth of various corals.

The second paper of the regular program was by Dr. J. N. Rose, "Botanical Explorations in South America." Dr. Rose spoke concerning a botanical exploration on the west coast of South America which he made during the summer and fall of 1914. He stated that when he took up the study of the Cactaceae for the Carnegie Institution of Washington, it was with the understanding that it should embrace not only herbarium and greenhouse studies, but extensive field work in all the great cactus deserts of the two Americas. His going to the west coast was therefore simply part of a large scheme for botanical exploration. He further stated that plans had been made for similar field work in the deserts of the east side of South America during the coming summer. He gave detailed accounts of his work in the deserts of Peru, Bolivia and Chile, and the peculiar Cacti which he found, described particularly the climatic conditions in those countries, and told of the remarkable crescent-shaped sand dunes of southern Peru. On this trip Dr. Rose collected more than a thousand numbers, obtaining not only herbarium and formalin, but also living material. His collection of living plants which was very large has been sent to the New York Botanical Garden. Dr. Rose's communication was illustrated by maps of the regions traversed, by apparatus used in collecting speci-

mens, and by preserved specimens. The paper was discussed by Messrs. Hitchcock, Vaughan, Goldman and Townsend.

THE 536th meeting of the society was held in the Assembly Hall of the Cosmos Club, Saturday, February 20, 1915, called to order by President Bartsch at 8 P.M., with sixty-five persons present.

Dr. Charles Monroe Mansfield, of the Bureau of Animal Industry, on recommendation of the council, was elected to active membership.

Under the heading of Brief Notes, General Wilcox made observations and inquiries concerning the color of the eyes of certain turtles. His remarks were discussed by W. P. Hay. Dr. Howard described the successful campaign carried on against mosquitoes in New Jersey.

Under the heading Exhibition of Specimens, Wm. Palmer exhibited the tip of the tongue of a sulphurbottom whale and considered the probable use of its peculiar shape. Messrs. Bartsch, Hay and Lyon took part in the discussion.

The regular program consisted of an illustrated lecture by H. C. Oberholser, entitled, "A Naturalist in Nevada." Mr. Oberholser gave an account of a biological survey of parts of Nevada made by himself and others some years ago. He described the geologic, geographic and climatic characters of the route traversed by his party. He mentioned in particular the plants, the mammals, birds and reptiles observed and collected by the expedition; and pointed out how they were influenced in kind and numbers by the unusual geographic and climatic conditions found in Nevada. He showed many excellent views of the country and of the animals and plants encountered.

Mr. Oberholser's paper was discussed by Messrs. Hay, Bartsch, Bailey, Lyon, Goldman, Wetmore and Wm. Palmer.

M. W. LYON, JR.,
Recording Secretary

THE ANTHROPOLOGICAL SOCIETY OF WASHINGTON

At a special meeting of the society, held November 3, 1914, at the public library, Dr. J. Walter Fewkes read a paper on "Vanished Races of the Caribbean." The aborigines who, in pre-Columbian times, inhabited the West Indies, represent a vanished race, for with the exception of very incomplete historical accounts and a few highly modified living survivors, archeological remains only are left from which to determine their culture. The Antillean culture belonged to the stone age, and while it had attained a considerable development, it was quite unlike that of any other

area in the New World. These islands were peopled from the neighboring continent, but the peculiar types of stone objects which occur on the islands indicate that the culture they represent originated where it was found. This culture was of two types, one in the Greater Antilles and the other in the so-called Carib islands. These differ mainly in the forms of stone implements, pottery and other artifacts. For instance, 90 per cent. of the stone implements of the Greater Antilles have the form of celts, while the majority of implements from the Lesser Antilles are axes. This difference in the culture was noticed by Columbus and the early chroniclers. The inhabitants of the Lesser Antilles were called Caribs, the others Arawaks. The Caribs were preceded by an agricultural people whom they conquered in pre-Columbian times. All the islands from Cuba to Trinidad once had a highly developed population, which remained until later times only in the Greater Antilles. It is probable that the aborigines of the Lesser Antilles came from South America, but those of the Greater Antilles from Central America.

At a meeting of the society, held November 17, 1914, in the public library, Rev. Dr. John Lee Maddox, chaplain in the United States Army, read a paper on "The Spirit Theory in Early Medicine." The primitive theory is that disease and death are abnormal, the work of malevolent spirits or of witchcraft. Many modern remedies and practices are the direct descendants of old-time methods and drugs intended to cure the patient by driving out an evil spirit through fear or disgust. Bitter medicines originated in revolting doses intended to disgust the demon. Massage originated in the beatings and poundings through which the evil spirit was to be frightened out of the patient. Bleeding, cupping and trephining were originally intended to facilitate its exit. Through long centuries, even with an incorrect theory, it was learned that certain drugs and remedies had a beneficial effect upon certain diseases. Thus the correct practice developed long before the correct theory. As examples of standard remedies derived from Indian doctors, he instanced ipecac and quinine. In the discussion Dr. Fewkes drew illustrations from the Hopi Indians, Mr. Mooney from the Cherokee, and Dr. Moore from the St. Lawrence Island Eskimo. Dr. E. L. Morgan and others also spoke.

DANIEL FOLKMAR,
Secretary

THE UNIVERSITIES AND INVESTIGATION

As a representative of the university and as one but recently come to live among you, it is perhaps fitting that I should use the opportunity which President Hall has so kindly given me to discuss certain phases of university work in which many of my own chief interests lie, but which are not often brought before the attention of our public. I refer to the relations of the universities of the country to original investigation, and particularly to scientific investigation, since it is with a part of this—and necessarily in these days of specialization a small part—that I am personally concerned. Many of us in America have lived through a period in which the purposes and scope of the universities were at first not very clearly conceived; but as time has passed the situation has changed, and on the whole an agreement now prevails, which is likely to be permanent, regarding certain features of university policy which once were subjects of dispute. One of these is that investigation is an essential part of the work of every university. We now recognize that the universities have a double function to perform: one, that of disseminating liberal and scientific knowledge; the other, that of adding to it. There is nothing new in the idea that the chief concern of universities is liberal knowledge; i. e., knowledge of a kind not directed primarily toward special or utilitarian or personal ends, but scientific or humane knowledge, relating especially to those matters which have a broad human significance and general applica-

1 Founder's Day Address at Clark University.

bility. But in America it is only within the past twenty-five or thirty years that the universities have generally come to recognize it as their function to extend, as well as to maintain and transmit, such knowledge in all departments of learning. In a sense this is the more fundamental task of the two, since the attainment of scientific knowledge must precede its use in instruction or practical application; and it is perhaps the chief distinction of Clark University that it was one of the first to recognize and act on this principle. The day devoted to the memory of its founder seems thus an especially appropriate time for such a discussion.

Now investigation, in the scholarly or scientific sphere, means something more than the mere attempt to find something new. It means primarily all activity directed simply and solely toward the advancement of liberal knowledge—knowledge, that is, not of special or local or purely practical matters, but knowledge in its broader, more theoretical or purely humane aspects,—those which are concerned not so much with meeting the immediate occasion as with furnishing a generally valid basis of principles and methods that can be applied at will to all of the affairs of life. Breadth of application should be the main characteristic of this type of knowledge; it should meet not only the purposes of practical life, but also those of science and art, besides serving for the realization of the higher ideals of culture and conduct. The investigator knows that we can not assume all desirable knowledge of this kind to be already in existence and to be had for the asking; what we already possess has been gained chiefly by the prolonged and devoted efforts of previous investigators, working sometimes alone, sometimes in conjunction with others, and usually in universities or other institutions of learning; and we have to see to it that

the task is carried on. That the task itself is a worthy one admits of no dispute; incalculable good has come to humanity through its means, and no doubt will continue to come if our efforts do not relax.

Why do so many seek knowledge without being seriously concerned about its application? This question is often asked, and its answer has puzzled many sincere persons. In various fields of science and culture we find men who seek knowledge with no other aim than to possess it. Is this aim worthy? Many, especially in these times, express doubts. Some even denounce such search as selfish. One hears such expressions as the selfishness of cultured persons. Yet those who do possess knowledge—worth calling by the name—are rarely troubled by such doubts. When Solomon rated wisdom as better than rubies, he no doubt expected that philosophers in general would agree with him, but not all other persons. Is it that a certain native endowment of intellect or temperament is required to take satisfaction in knowledge as knowledge, just as others delight in art as art? This is true in a measure, certainly; and the tendency has to be recognized and I believe encouraged. It is doubtful if an investigator or scholar in any field can be truly effective without this disinterested curiosity or simple desire to know; so that we must regard love of knowledge, even if it does not eventuate in action of any kind, as in itself desirable. Perhaps it is as well for it not to exist alone, but that is another question. There are, however, other and profounder—I might say biological—justifications for this tendency. Knowledge, in the biological interpretation, is the chief means of adjustment to the conditions of life. This is clear enough in practical life; if we *understand* a situation—have it clearly and accurately conceived in advance—we are better able to deal with it. The

same is true of even abstract or remote knowledge of the purely scholarly kind; it is *potential* means of adjustment; the cultured man knows how to adapt himself to most circumstances better than the uncultured man. Not only mankind, but all living organisms—both animals and plants—are so organized that their well-being depends on accurate adjustment to the conditions under which they live. The give and take of material and energy must balance; the term “adaptation” means simply the sum-total of the conditions that secure this balance. Now, for us men, the chief means of such adjustment is knowledge. Theoretical or abstract knowledge, the kind that investigators in pure science strive for, is merely that which is the most universally valid and applicable; it is therefore at bottom the most practical; so that if the chief aim of scientific investigation is the attainment of such knowledge, and even if the wish to attain it is often purely instinctive and unreasoned—as in fact it is in many of the best investigators—we can understand from the biological point of view why this should be so. Thus there is the best of sanctions for the knowledge-seeking tendency. Breadth of knowledge represents a surplus or reserve of potential activity,—whether it is actually called upon for use or not; and as such it is the most valuable possession that we can have, for it is the means by which purposes of any kind are rendered capable of realization.

Now let me define a little more fully what scientific men mean by investigation. Under this term come all efforts directed toward the one aim—the ascertainment of the clear, impersonal and objective truth concerning the matter in hand. Mankind has found no method that leads so certainly to the attainment of this end as the method of dispassionate, systematic and critical inquiry, using all available means impartially

and thoroughly, and verifying all results once they are attained. In this sense scientific investigation is in no way different in its method from investigation in other fields, such as history, language or philosophy, or from the means which a good military commander or man of affairs adopts in familiarizing himself with a situation before he acts. In every case the aim is to ascertain impartially the actuality of the case, that which is so, quite independently of what our wishes or fears or other prepossessions may be. The means which we adopt may vary in different fields of investigation according to the nature of the matter under investigation; but the attitude of the true investigator is the same everywhere—an attitude of candid, critical, persistent and, above all, disinterested inquiry. It is important to realize the necessity for these qualities in the investigator, if true results are to be attained. Without them the purpose of investigation can not be realized; progress is slow, and results do not bear examination. Let me quote Faraday's conception of the natural philosopher—by which he means the investigator in natural science: “The philosopher,” says Faraday, “should be a man willing to listen to every suggestion, but determined to judge for himself. He should not be biased by appearances; have no favorite hypotheses; be of no school and in doctrine have no master. He should not be a respecter of persons, but of things. If to these qualities be added industry, he may indeed hope to walk within the veil of the temple of nature.” Here we have a statement, clear, simple and devoid of literary artifice, by one of the most fruitful scientific investigators of all times; and when we wonder at what has been accomplished by the science which has developed from beginnings largely made by him, we should remember that it is only by such men, working in such a spirit, that

the more fundamental truths can be brought to light. When, therefore, we say that we wish to encourage investigation, we really mean that we wish to encourage those who have the right spirit of investigation. Progress is due mainly to such men; and it is important in the interests of this progress that the universities, which devote so large a part of their resources to the work of investigation, should clearly recognize that the personal factor is still—as it was in Faraday's day—the all-essential. Knowledge, insight, and power of accomplishment are not in laboratories, libraries and organized institutions merely, but chiefly in those who put such means to their right uses.

It is needless, before an audience of this kind, to justify scientific investigation or to attempt to set forth something of what it has accomplished. I may, however, point out—since this has a bearing on much of what I wish to say later—one consideration which the world at large is prone to forget unless frequently reminded, namely, that it is the *fundamental* investigations which are chiefly important for science, and lay the foundations for those later applications affecting mankind generally. Thus in this sense we owe wireless telegraphy to Maxwell and Hertz rather than to Marconi, our freedom from many forms of disease to Pasteur, our mastery of the air to Langley and the others who studied the lifting power of moving planes; and many other similar examples could be given. In general we may say that if an adequate body of theoretical knowledge has once been gained, it is a relatively easy matter to make the desired practical applications. It is when there is no guiding theory and we have to work empirically that problems are difficult or impossible of solution. But if we know beforehand of any task that nothing but hard work and persistence is necessary

for its accomplishment, we may say that there is no serious difficulty, for these qualities can be commanded at will in any civilized society. When, however, we lack the necessary knowledge of fundamentals, little or nothing can be done. I may here furnish an illustration from biological science. Until the relation of microorganisms to disease was discovered by Pasteur, physicians were almost helpless in many departments of medicine; but once this relation was established, means for indefinite advance were at once furnished; then, to use Ehrlich's phrase, "*diligent empiricism*" was all that was needed to master many problems of pathology; and, these once mastered, effective methods of diagnosis and treatment were forthcoming sooner or later. The relation of Faraday to electrical science is similar; and in the same sense engineering, scientific agriculture and mining, many valuable manufacturing industries, in short, all that is most characteristic in the material foundation of our civilization, could never have come into existence without the previous development of the pure sciences of physics, geology, chemistry and mathematics. Other and less tangible results are of equal importance, but it would lead too far to speak of these. I wish simply to make it clear that the fundamental knowledge must first be gained; and it is the task of the investigator to supply this knowledge. This he can do only by prolonged study, observation and experiment, directed toward the simple purpose of obtaining as full and clear insight as possible. In the pursuit of this aim problems inevitably arise that are both difficult and remote from popular interests; yet such problems must be solved, and it is largely for the purpose of providing opportunity and facilities for their solution that universities exist. This is why the greater part of research in pure science is necessarily conducted in the uni-

versities. On the other hand, experience has shown that those parts of scientific work which relate directly to useful applications can be carried on successfully under the pressure of general public demand; the material rewards of successful invention are a sufficient incentive to inventors. This, however, has never been true of investigation in fundamental fields of pure science, and it is difficult to see how it ever can be true. Such work itself is its own chief reward. Isolated men of genius may make great discoveries, as Boyle, Cavendish and Darwin have done in England; but in such cases fortunate circumstances and leisure are essential, and the number of such men is very small. For most investigators the opportunity of engaging in purely scientific or scholarly investigations is to be found only in the universities. The relation of universities to fundamental scientific progress is thus a peculiarly intimate one.

Advance in knowledge, as distinguished from the maintenance and application of existing knowledge, thus depends ultimately on the work of the investigator, and chiefly on the investigator in the university. If he is to accomplish his function he must direct his efforts to the practicable, under conditions that are favorable to his work—or at least not too unfavorable, for good will and talent can accomplish much in spite of adverse conditions. First, what is practicable? In his "Advancement of Learning" Bacon, the first advocate of systematic investigation, says:

I take it those things are to be held possible which may be done by some person though not by every one, and which may be done by many, but not by any one, and which may be done in a succession of ages though not within the hourglass of one man's life; and which may be done by public designation though not by private endeavor.³

³ I wish to express my indebtedness for this quotation to Dr. Mall's interesting article in the *Journal of the American Medical Association*, 1912, Vol. 60, p. 1599.

Bacon thus recognizes that many projects call for collective and coordinated endeavor, while others require individuals gifted with the necessary talents or opportunity. Collective action and individual action both play a part, and this is as true of the advance of science as of any other form of enterprise. Now it is a characteristic of our time and country that more stress seems to be laid on the importance of collective action or cooperation in scientific research, than on the importance of giving scope to the single investigator of original scientific genius. Whether this tendency is right or wrong I need not discuss just now. It is clear that cooperative research is essential for the solution of many scientific problems, especially those requiring the accumulation and coordination of large masses of data. Much of the work in statistics, heredity, astronomy, geology, sociology, and other sciences is of this nature; here are illustrated Bacon's classes of work "which may be done by many, but not by any one, or which may be done by public designation but not by private endeavor"; one has only to think of what is done by geological surveys, statistical associations, or scientific societies. Work which can not be done "within the hourglass of one man's life" may be well within the scope of an association; thus we have investigations relating to natural events which recur infrequently, like earthquakes or sunspot periods, or to processes which take place very slowly, like evolutionary changes in organisms, star movements, or other cosmic changes. Only the coordinated work of generations can throw light on such matters. Cooperative research thus plays an important part in the science of to-day, and there is a strong tendency on the part of many scientific men to insist on its all-sufficiency, and to regard the work of isolated or independent investigators as of minor consequence.

Bacon, however, mentions first of all the class of achievements that are possible to some one person, though not to every one. That in certain spheres of activity one person may be indefinitely superior to any other or even to any combination of others was familiar enough to Bacon, and social conditions were not then such as to obscure this truth or throw doubt upon it. Being a man of genius himself and an advocate of progress, he could not underrate the part which personal originality and power of invention play in progress; he knew that such qualities are of individual and not of social origin, although they naturally flourish best in a favorable social environment. It is perhaps time to protest against the tendency to undervalue detached investigators, which insists that every one shall work chiefly in cooperation with a group and for a collective aim. This tendency is undoubtedly strong at present, especially in America, because here the democratic spirit is more dominant than anywhere else and is subject to fewer corrective influences; and the resulting bias toward collectivism tends to lower the estimate placed on purely personal or individual qualities. Now reliance on "team-play" is well enough in its place; it plays an indispensable part in many undertakings. But such a spirit cannot be depended on to promote scientific progress by itself; in this sphere it is at best rather an accessory. The truth is that so far from progress depending on collective effort, the whole history of science shows that the guiding and fruitful ideas, those which form the seeds of later developments, nearly always originate in the minds of a few scattered thinkers or investigators, often working in isolation. Is there any reason to believe that this will not continue to be the case? Yet high scientific authority seems at times to encourage that belief. President Woodward, of the Carnegie Insti-

tution, in a recent address¹ warns his hearers against entertaining what he calls the subtle error that

the more remarkable results of research are produced not by the better balanced minds, but by aberrant types of mind popularly designated by that word of ghostly if not ghastly implications, namely, genius.

Again he says:

The more striking results of research, quite commonly in the past attributed to wizards and geni, and still so attributed by a majority perhaps of contemporary writers for the popular press, are now understood by the thoughtful to be the products rather of industry, sanity and prolonged labor than of any superhuman faculties.

Others extol cooperative research as the highest type of scientific work. But surely what is understood by scientific genius is not a wizard-like faculty of arriving at immediate and astonishing results, but rather that power of clear, imaginative and valid insight into phenomena which is the product of high native endowment combined with industry, sanity and prolonged labor. The peculiarities of pseudo-genius—which no doubt has besieged the Carnegie Institution for support from the beginning—should not be allowed to cast discredit on true genius, a totally different thing. When we understand clearly what scientific genius really is, we must recognize that it is no less indispensable to the production of the highest scientific work than is poetical genius to the production of the highest poetry. Every-day experience proves that industry, sanity and prolonged labor are not sufficient for the best work in any domain. It would be fortunate for humanity if it were so; for these qualities are not rare, and are in a measure attainable by all normal persons. Genius is not these—although when these are added genius may become more effective. Unfortunately—or perhaps fortunately—it evades rules; but it seems to

¹ SCIENCE, 1914, N. S., Vol. 40, p. 217.

include a strong instinctive element which appropriates or rejects the material which is presented to it—either by its own vivid imagination or by outside experience—according to the availability for the purposes that interest the genius. And this interest is likely to be absorbing to an extreme degree, and hence to arouse all the energies much more effectually than is usually possible to normal persons. But it is not necessary here to prejudge questions which are still a puzzle to psychologists. I wish merely to emphasize that whatever a final analysis may eventually show genius to be, there is no doubt of its existence, that it is rare, and that the chief achievements of mankind in science, as in art and literature, are due in the main to its activity. Only by recognizing these facts shall we be able to take properly into account all of the factors which contribute to scientific progress, and make due provision for all. If Darwin had been without means, there is no doubt that the most effectual way of promoting evolutionary science in his day would have been to provide him with an adequate personal endowment, or a university chair giving complete freedom for research. I emphasize this in order to bring to your attention the all-importance of the individual or personal factor in the work of scientific investigation. This consideration is a wholesome one for moderns to bear in mind; for the trust in cooperative methods, "team-play," and collective enterprise is so general, and has assumed such a dogmatic character, that it tends to deprive many persons—especially those whose talents are of a subtle rather than a robust order—of belief in their unaided personal powers, and hence to weaken their sense of personal responsibility. One result of this often is that they lose the normal and healthy compunction against laying up their talents in napkins.

Let us now return to our original subject. One of our aims in the universities is to further investigation. How are we to do this most effectually? The answer, in form at least, seems simple. First we must provide facilities, and second, we must have the right men. The first requirement is relatively easy; it is a question of material resources; the second is more difficult, as well as more important, for if it is impossible to make bricks without straw, it is still more certain that the best of straw will serve little for brick-making unless put into the right hands. But let us define a little more closely what we may regard as the conditions of successful research, with especial reference to the case of scientific departments in universities. In general three things are necessary; equipment, proper co-ordination of activities (or organization) and personnel. When these are combined in the right proportions we may hold that conditions are the most favorable; but this is not always possible, and usually some choice has to be made; which is the most important and fundamental? This question is not easy to answer; so much depends on what is under investigation; a completely and expensively equipped laboratory can undertake researches which are beyond the reach of one of more modest resources; and yet the difference in the importance of the results gained by the two may not be commensurate. Here we see the significance of the personal factor. Darwin will make important discoveries in his kitchen or back yard, while a costly laboratory, although making a great show of activity, may be comparatively fruitless in important results. This fact, however, does not make it any the less desirable that the apparatus for research should be at hand; but it indicates that if results are to come, such means should be used properly, and this can be done only by the right men. Appeals for

equipment have on the whole been well met in this country; and our relative lack of scientific productivity has little if any relation to lack of equipment. Nor is it for lack of numbers and organization that the universities fall short in scientific productivity. Everything that organization and system can do is done in our larger universities. Officers from the president down are numerous and minutely graded, hierarchy within hierarchy; there are departments and subdepartments; every subject is represented by one or more specialists; the courses given in a large department are numerous and detailed and cover all phases of the subject. The work of students is carefully supervised; so many credits go to the making of a master's, so many to a doctor's degree. No one is idle for a minute. The mere mechanism requires exacting care; the head of a department must often be primarily an executive; much of the time is given to duties of management; the telephone, the typewriter and the card-index are as much a part of his equipment as of the business magnate's. It would seem as if all of this machinery ought to be effective. Yet misgivings force their way in. There is reason to think that this faith in the efficacy of organization in university work is not derived from experience, but rather from a preconceived belief that methods which are so effective in practical life ought to be equally so in the intellectual life. But is this really so? Many of us have grave doubts. In our own private studies devotion to card-catalogues and notebooks can go too far, as many a man has found from bitter and paralyzing experience. Is it really true that the letter killeth, but the spirit giveth life? There must be conditions more important than equipment and organization—conditions which are somehow lacking. What are they and how can they be furnished?

It is for the universities to make the right answer to this question, and also to rectify the conditions. The majority of productive scholars and investigators are connected with universities. If the scientific productivity of the nation is less than it ought to be, as we see when we compare ourselves with Germany, France or England, we can only ascribe the deficiency to the presence of unsatisfactory conditions in the universities. What are these? and how are they to be removed?

Such a question carries very far and admits of no off-hand answer. The universities represent the intellectual tendencies of the country. They are, or ought to be, one of the chief sources of what is highest in its civilization. Why do fundamentally important contributions to science or scholarship come so infrequently? and is there any way of making them come more frequently? What man has done man can do: there must be some restricting and removable conditions which either prevent original investigators from doing their full quota of good work, or it may be prevent the creative type of scholar from finding his way into the universities in the numbers that we have a right to expect. What the chief of these conditions are, and how all those interested in the welfare of our institutions of learning can aid in their removal and replacement by better, is what I shall now try briefly to indicate. I ought perhaps to say that I offer my suggestions in a far from dogmatic spirit, being aware that the problem is highly complex, and that no one man can be fully familiar with all of its aspects.

When we look at our universities we are impressed with certain obvious peculiarities—their size, their wealth, the variety and complexity of their activities and of their organization. We may agree that size and wealth with the resources that they bring

are all very well—in themselves desirable—but complexity of organization, and the practices and tendencies that go with it are these conducive to the intellectual life? This, in my opinion, is the critical question. So far from our taking this for granted, there is good reason to believe that beyond a certain limit dependence on system and organization in institutions of learning is directly injurious to good work, and this for the simple reason that it makes for the stereotyping of activities, and hence interferes with freedom and its expression, which is originality. Such restriction in fact is the general purpose of organization; it aims at diminishing variation from an accepted norm. Now the more stereotyped certain things are the better; thus a railway service or a department store can not be too regular and dependable; but if our aim is not simply to repeat things already done, but to discover new truth, the conditions that surround us, as well as our own temper of mind, should so far as possible encourage independent activity, and not simply that carried out in accordance with a program. In brief, purely routine activities should be subordinated in an institution of higher learning; all needless machinery should be disposed of, and the rest should be relegated to its proper place. This is a practical suggestion, and it is one of the first that I should make.

I do not, of course, wish to propose anything impracticable, and I am aware that a certain degree of established order, inseparable from organization of some kind, is necessary to stability and efficiency even in an institution devoted purely to research. But what I maintain is that the aim should be a minimum rather than a maximum of organization, and that the ideal toward which universities should work, if they regard original scholarship as something which it is their serious duty to further, is the attain-

ment of the greatest possible freedom in the work of the individual departments and of the scholars making up those departments. A system of separate colleges, as in the English universities, or of autonomous departments, as in the German and some American universities, seems to give the best results. Such an ideal should not be left to chance, but it should be held consciously; and every one in the university should regard such freedom as the chief condition of his effective activity and should oppose vigorously every attempt to infringe upon it. Liberation must come from within rather than from without, and as the result of a more widespread insistence on the importance of personal freedom and initiative. This spirit would be incompatible with the over-developed autocracy that has aroused so much complaint. Freedom from merely petty and distracting activities would then soon come, and more men would give the best part of their attention to things that are seriously worth while.

The university should be the stronghold of individuality. Every one's serious interests should be respected and furthered so far as possible, both out of regard for personal freedom, and also because we do not know what their potential value may be. Remember that our aim as original scholars is not simply to impart what is already known and valued, but to produce something new, whose value to the world may not be in the least evident at first. But who can tell what its value may be later? Besides, it may be of value to the few if not to the many. We must recognize that the needs of men are as various as their characters and capabilities. A tolerance, open-mindedness, and detachment are thus of the essence of true academic life. An unwillingness to interfere needlessly, coupled with a determination to adhere by

high standards, may indeed be said to be the chief criterion of a high civilization.

There is reason to believe that the democratic movement of our time has in many ways been unfavorable to the development of strong individuality in the fields of science, literature and the arts. The collective spirit is now dominant, especially in America, and even in academic life many are unduly influenced by the desire of producing work which will make a direct appeal to the community at large, rather than work which is new and meritorious in itself, irrespective of whether it is popular or not. This spirit is inconsistent with disinterestedness, and hence tends to repress originality. It is hard to escape its influence; it constitutes an atmosphere—that element which is at once the most intangible and the most essential to life. We can however resist it if we only wish; and a spirit of independence or self-respect, that refuses to have its standards determined by anything short of firmly grounded personal conviction is the best safeguard. There is a sense in which too easy submission to the prejudices of a majority is like too easy submission to the dictates of a king or emperor. In either case the result is weakening to individuality, and hence to all work, like the work of scholarship, which demands independence and individuality.

We must remember that we are living in a time which tends to regard the collective welfare as the chief if not the only legitimate object of action. In one sense this is a great source of encouragement; it augurs well for the future of humanity at large; but it has its drawbacks. Little attention is paid, except by a few detached persons here and there, to the danger of having the whole national spirit dominated by the belief that nothing but work in the interest of large numbers is of any importance. Related to this is another very char-

acteristic tendency. Where so many questions in politics and practical life are decided by counting of heads, a strong bias in favor of mere numbers is inevitable. Now there may be no disadvantage in this unless it becomes instinctive, *i. e.*, acted upon automatically and uncritically; but it is just this instinctive prejudice that prevails so strongly nowadays. All forms of activity share its influence; and it shows itself in educational institutions and universities in such phenomena as an over-insistence on the importance of large enrolments, the conferring of too numerous degrees, and a distinct and widespread tendency to leniency in the standards of quality. Public opinion in a democracy favors these manifestations, and an institution dependent on public opinion for its support can not afford to be too unsympathetic toward them. But a danger lies here, which is perhaps the more insidious since it can be recognized and guarded against by comparatively few. If we work only in the interest of and at the bid of majorities, we are in grave danger of disregarding the claims of the minorities. And this means undervaluing those types of person who are necessarily always in the minority, *i. e.*, exceptional persons of all kinds. The curious result follows that in a democracy, the political system which is theoretically the most favorable to liberty, the individual, regarded as an individual—and not as representative of a group (whose numbers may entitle it to respect)—often meets with little consideration. In other words, too much respect for collectivism tends to impair the respect which is due the individual, and personal liberty suffers. There arises a tendency to treat all persons in the mass, indiscriminately; and necessary distinctions fail to be made. Complaints of the low estimate which the democracies of England, France and America place on even the best and most gifted in-

dividuals have been appearing somewhat frequently of late; Faguet even says that the equalitarianism of the time leads to a distrust of all but mediocre persons in every capacity, and indeed favors a cult of incompetence; and he ascribes much of the inefficiency and shiftlessness of democracies to this tendency. This may be partly overstatement for purposes of emphasis; but it is at least clear that if the universities are to do their best work they should be consciously on their guard against such tendencies. We must remember that in a sense the statement that all men are equal is a dogma adopted primarily for political purposes; as such it embodies an important principle, and it serves to simplify the technique of representative government; but it was never meant to controvert plain facts. In any case we must avoid being influenced by it to the extent of disregarding talent and failing to do our best to single it out and develop it. Real progress can come only in this way. This policy, however, seems to be unpopular at present, and as a rule is little acted on in our universities. Thus the attempt to make a definite distinction between "honor" men and "pass" men—a distinction corresponding on the whole to that between those who seriously wish to study a subject and those who have no particular interest in it—is opposed as undemocratic. One often gains the impression that talented students do not try their best, because they have a feeling that it is not quite considerate or democratic for one man to prove himself the intellectual superior of another. Why this should be so is one of the mysteries; there is no such feeling about games like tennis. It may be that it represents a defensive reaction in the biological sense; it is said that white sparrows are badly treated by normal birds; and no doubt many persons feel safer when they identify themselves with

a group than when they stand alone. The spirit of hostility to distinction is, however, peculiarly out of place in universities. It is difficult to judge our own community and our own time; we are subject to the fallacy of nearness; but there is little doubt that a general desire to regulate the activities of the individual in the supposed interest of the group is at present one of the most characteristic manifestations of the time-spirit, and that a submission to this desire by persons who think it democratic so to submit is responsible for a certain lack of distinction and originality in the intellectual activities of the day. The way in which organizations and societies flourish is a symptom of this; the remark has recently been made that whenever two or three are gathered together nowadays some one else is sure to be on his way to organize them; and this propensity encourages the individual in a kind of fatalistic belief that he can accomplish nothing working alone. Under these conditions, if he fails, he is often inclined to cast the blame on the organization to which he belongs or on the community rather than on himself.

It is essential that we should continue to regard the university as a place where individual talents of the most special kind will receive encouragement and development, as a place of preparation for leadership, and equally for the discouragement of any inclination to lean unduly on the rest of the community. The university man should be able to think for himself and by himself. No one can say what the potentiality of any one may be; if, therefore, a student is conscious that he has any special bent or enthusiasm for any subject, he should not hesitate to give his chief energies to its cultivation. It may be that he will meet with little sympathy from the outside world, or even from his intimates; but this should be no cause for discouragement. The univer-

mity exists largely to give opportunity to men of this kind. He must get over the feeling that it is necessary, or at least fitting, to apologize for the unpractical nature of his activities. The university is aware that many things can be done only by taking thought, just as others require immediate action without any particular thought. There is inevitably isolation and detachment in much of the work of universities; this is especially true of the work of investigation. Remember Wordsworth's lines on Newton's statue at Cambridge University:

The marble index of a mind forever
Wandering through strange fields of thought alone.

The withdrawal of such a man from the world is deliberate; only so can his purposes be achieved.

This withdrawal imprints a characteristic quality on academic life, with which it is often reproached. The very word academic is often popularly or journalistically used to signify remoteness from actuality. It might with equal justice be used as signifying *nearness* to actuality; but the fact is simply that the university recognizes as important or even pressing actualities many matters which to the world at large are virtually non-existent. The apparent ineffectuality of much academic work is a serious grievance to many people; and certain movements directed toward the radical modification of time-honored academic usages and privileges have arisen as the expression of this feeling; some persons, no doubt conscientious, have favored a system of supervision and time-keeping, with the object—laudable, no doubt, if only it were practicable—of making sure that the holders of university chairs do not waste their time. But it is just here that the uninitiated judgment is likely to lose its bearings; and we may well continue to repeat with the Sybil: "Procul este, profani!" Who is to be the

judge in these matters? Who will guard the guardians? What constitutes effectuality in the intellectual sphere? We must refuse to be misguided by false criteria in these matters. What is most effectual in the activities of the scholar can not always be discerned even by his immediate associates. Nothing but the perfect witness of all-judging Jove would suffice for this. The true criteria are not evident to those ignorant of his work; and in forming an estimate of its value, confidence and respect for individuality have to be combined with the judgment passed by his peers in the learned world. If for lack of sympathy or special knowledge we fail to see the value of certain fields of scholarly work, there is nothing for it but to accept the assurances of those who know. Their judgment is likely to be critical enough, and not to err on the side of leniency. All plans of imposing upon the scholar rigid requirements from without—apart from the necessary responsibilities of teaching and contributing to his subject—are impracticable. I have mentioned certain recent attempts directed toward a closer external oversight of academic work; the authors of these attempts have urged that it would be well, in the interests of "efficiency," to estimate more closely the time which the occupants of university chairs devote daily to research, to teaching and to other activities. This is officialism run mad, you may say; but there the fact stands. Some one, well known as a defender of academic freedom, has remarked that the only really effective scientific mind works twenty-four hours a day. In saying this he may have had in mind Lander's passage:

The capacious mind neither rises nor sinks,
neither labors nor rests, in vain; even in those
intervals when it loses the consciousness of its
powers it acquires or recovers strength, as the
body does by sleep.

If this is true, it is clear that all such attempts to enforce scientific productivity—usually under the delusion that it represents measurable and controllable “output” like the products of a factory—are futile, and overlook the essential requirements of all original work, which are simply opportunity, freedom from needless distraction, and the necessary leisure.

Regarding this last requirement a word or two is peculiarly apposite nowadays. Jesus, the son of Sirach, says: “The wisdom of a learned man cometh by opportunity of leisure”; and he goes on to explain that merely multifarious activities of the more obvious kind are injurious to such a man, since they hinder and distract him from more worthy tasks, and prevent his accomplishing what is truly worth while. For this, tranquillity is needed, and the depth that comes from prolonged and undisturbed concentration. This is an essential condition for the work of investigation; activity is useless unless properly directed; but direction requires thought; and thought requires time for thinking—which is leisure. Wordsworth says very profoundly in “*Laodameia*”:

. . . The Gods approve
The depth and not the tumult of the soul.

I do not know of any more suitable motto for a university than just this. For, after all, it is depth we want; and no degree of external activity, however effective or apparently beneficial, can make up for its lack. But how can it be gained without leisure—freedom for thought and study and research, and belief in their efficacy and saving grace? Such freedom is the source of all spontaneity and originality. You all remember how, when an admirer expressed his delight over the perfection and inevitability of a line of Tennyson, and said he knew that was a pure stroke of inspiration, the poet replied: “Well, I smoked three

pipes over that line.” Now it may be that not all affairs can be conducted in that way; we in the universities should recognize this and not be disturbed by it, while maintaining, nevertheless, that our ways are different. We form a sanctuary for all those who, whether by smoking pipes or otherwise, can by the power of thought, and activity directed by thought, attain the essential truth in any matter. I do not speak here of the beautiful; that is the realm of art. But in scholarship what is essential is *ideas*; it is these which give value and interest to the often dry details of investigation, and which guide and inspire the work of gathering fresh detail. We find that if we have the ideas we can usually test their validity without great difficulty; but they are the indispensable, and we can not get them without thinking and studying deeply. For that we require leisure. I dwell on these considerations because there is little doubt that our day and generation does not sufficiently recognize the need of leisure in academic life, and often misunderstands its purpose. Yet it is essential that there should be an atmosphere of leisure—of freedom from external compulsion—in the universities, if they are to be fully and adequately productive in original scholarship. We must understand clearly the purpose of such leisure, which is simply to afford opportunity—not for idleness, as I need hardly say, but for fruitful independent effort. In this sense leisure should be the chief prerogative of the educated man everywhere. It really implies nothing but freedom, and for its proper use both discipline and high purpose are needed. The knowledge and the will to use freedom rightly—surely these are what all who are truly educated ought to have; and we must be willing first of all to assume that those who are entrusted with the tasks of education and the advancement of learning are

especially fit to be entrusted with their own freedom. It is likely that an enlightened society can be relied on to recognize this; but it is particularly the duty of the universities, if they believe in their own best traditions, to speak with no uncertain voice. We look chiefly to them for progress in those fundamental fields of knowledge which ultimately concern more intimately than any others the future of civilization; and if they are to continue their leadership they must show that they value above all immediate advantages the tradition of academic freedom.

RALPH S. LILLIE

CLARK UNIVERSITY,
February 1, 1914

THE NATIONAL ACADEMY OF SCIENCES

The Academy will hold its annual meeting at Washington on April 19, 20, 21, 1915. The program is as follows:

MONDAY, APRIL 19

10 A.M.—Business meeting of the Academy in the Oak Room of the Hotel Raleigh.

1 P.M.—Luncheon in the private dining-room of the Hotel Raleigh.

2.30 P.M.—Auditorium, National Museum. Public scientific session:

Thomas H. Morgan: "Localization of the Hereditary Material in Germ Cells." (30 minutes.)

Problems of Nutrition and Growth:

Jacques Loeb: "Stimulation of Growth." (30 minutes.)

Lafayette B. Mendel: "Specific Chemical Aspects of Growth." (30 minutes.)

Eugene F. Du Bois, medical director, Russell Sage Institute of Pathology (by invitation of the program committee): "Basal Metabolism during the Period of Growth." (30 minutes.)

I. S. Kleiner and S. J. Meltzer: "Retention in the Circulation of Injected Dextrose in Depancreatized Animals and the Effect of an Intravenous Injection of an Emulsion of Pancreas upon this Retention." (10 minutes.)

5 P.M.—Meeting of the editors of the *Proceedings, Cosmos Club*.

8 P.M.—Auditorium, National Museum.

First William Ellery Hale Lecture, by Thomas

Chrowder Chamberlin, of the University of Chicago. Subject: "The Evolution of the Earth." (Illustrated.)

The lecture will be followed by a conversation in the Art Gallery of the National Museum.

TUESDAY, APRIL 20

10 A.M.—Auditorium, National Museum. Public scientific session:

Joel Stebbins, Draper Medallist: "The Electrical Photometry of Stars." (30 minutes, illustrated.)

George E. Hale: "A Vortex Hypothesis of Sun Spots." (20 minutes, illustrated.)

Edwin B. Frost: "The Spectroscopic Binary, Mu Orionis." (10 minutes, illustrated.)

Robert W. Wood: "One-dimensional Gases and the Experimental Determination of the Law of Reflection for Gas Molecules." (10 minutes, illustrated.)

Robert W. Wood: "The Relation between Resonance and Absorption Spectra." (15 minutes, illustrated.)

Edward L. Nichols and H. L. Howes: "On the Polarized Fluorescence of Ammonio-Uranyl Chloride." (15 minutes, illustrated.)

Robert A. Millikan (by invitation of the Program Committee): "Atomism in Modern Physics." (30 minutes, illustrated.)

1 P.M.—Luncheon in the Oak Room of the Hotel Raleigh.

2.30 P.M.—Auditorium, National Museum. Public scientific session:

William Morris Davis: "Problems Associated with the Origin of Coral Reefs, suggested by a Shaler Memorial Study of the Reefs of Fiji, New Caledonia, Loyalty Islands, New Hebrides, Queensland and the Society Islands, in 1914." (60 minutes, illustrated.)

F. W. Clarke: "Inorganic Constituents of Marine Invertebrates." (15 minutes.)

Boy L. Moodie (introduced by Henry Fairfield Osborn): "Amphibia and Reptilia of the American Carboniferous." (15 minutes, illustrated.)

Henry Fairfield Osborn and J. Howard McGregor: "Human Races of the Old Stone Age of Europe, the Geologic Time of their Appearance, their Racial and Anatomical Characters." (15 minutes, illustrated.)

Charles A. Davis, geologist, Bureau of Mines (by invitation of the Program Committee): "On the Fossil Algae of the Petroleum-yielding Shales of the Green River Formation." (15 minutes, illustrated.)

Nathaniel L. Britton: "The Forests of Porto Rico." (10 minutes.)

J. Walter Fowkes: "Pictures on Prehistoric Pottery from the Mimbres Valley in New Mexico, and their Relation to Those of Casas Grandes." (20 minutes, illustrated.)

Charles B. Davenport: "Inheritance of Temperament." (15 minutes.)

Charles B. Davenport: "Inheritance of Huntington's Chorea." (12 minutes.)

8 P.M.—Annual dinner of the members of the Academy and their guests and presentation of the Draper medal, held in the Oak Room of the Hotel Raleigh.

WEDNESDAY, APRIL 21

10 A.M.—Oak Room, Hotel Raleigh.

Business meeting of the Academy for the election of members and two members of the council.

1.30 P.M.—Luncheon in the private dining-room of the Hotel Raleigh.

2.45 P.M.—Auditorium, National Museum.

Public scientific session. George H. Parker, official representative of the academy upon the Special Commission appointed by the President of the United States to study and report upon the Alaskan fur seals during the summer of 1914. Subject: "The Fur-Seal Herd of the Pribilof Islands." (Illustrated.)

4 P.M.—Auditorium, National Museum.

Second William Ellery Hale Lecture, by Thomas Crowder Chamberlin, of the University of Chicago. (Open to the public.) Subject: "The Evolution of the Earth." (Illustrated.)

JACQUES LOEB: *Stimulation of Growth.*

The speaker intends to discuss the stimuli which induce development and growth in three cases.

1. *Artificial parthenogenesis*, or the nature of conditions which cause the egg to develop. It has been shown that all substances which cause a cytolysis of the surface layer of the egg start the development; and that the spermatozoon must contain a substance of that character; but that in addition a second treatment is required to insure a more normal development. The alteration of the surface layer increases the rate of oxidations in the egg by 400 to 600 per cent. and the same effect is produced by the entrance of the spermatozoon into the egg.

It seems that under certain conditions this alteration of the surface is reversible and it is inferred but not yet proven that in this case the acceleration of the rate of oxidations is reversed. This reversibility is a fundamental fact, since the altera-

tion of conditions of active growth and rest are a prerequisite for the continuity of life.

2. *Metamorphosis*. Phenomena of growth occur in the larval metamorphosis when certain organs disappear and new ones begin to grow. A number of facts have indicated that substances circulating in the blood are responsible for these phenomena of growth and this conclusion was put on a permanent basis by the discovery of Gubernatch that it is possible to induce in tadpoles at any time the outgrowth of legs and complete metamorphosis by feeding them with thyroid.

3. *Regeneration*. By regeneration we mean the phenomena of growth started by the removal of some part. It can be shown that in these cases also the growth is induced by the collection of (probably specific) substances at places where they could not gather under normal conditions.

LAFAYETTE B. MENDEL: *Specific Chemical Aspects of Growth.*

A review of the methods employed in the investigation of chemical problems of growth. Analysis of the tissues of growing individuals has failed to contribute much of specific importance, owing to the tendency of the body to maintain a fixity of composition under varying conditions of diet. The study of nutrition in growth is more profitable. This has involved a determination of the constructive units essential for the building up of an adult organism. Recent contributions respecting the rôle of the individual nutrients, and particularly the proteins, are considered. The part played by the amino acids derived from proteins in digestion has been investigated. Some of these can be synthesized in the organisms; others apparently can not, and must be furnished in some form in the dietary. The newer researches suggest that in addition to the familiar foodstuffs certain as yet undetermined food accessories (also called "vitamines") are needed. The evidence for this view and the facts regarding the existence of special chemical determinants of growth are discussed.

EUGENE F. DU BOIS: *The Basal Metabolism during the Period of Growth.*

In order to compare the basal metabolism of children with that of adults it is best to use as a basis the calories per square meter of body surface per hour. The average figure for men is 34.7 calories with a plus or minus variation of 10 per cent. For a short time after birth the average for infants is 20 per cent. below this figure. The metabolism then rises rapidly and reaches a point 50 per cent. above the adult level at the age of 2 years, remaining at this height until the age of 6

years, then falling steadily until the age of 19. From this point there is very slight decrease before old age is reached. During convalescence from typhoid fever the curve of metabolism is similar to that of childhood. The evidence points towards an increased metabolism of growing tissue. The fact that the liver and thyroid gland are relatively large in children may account for part of the increase.

I. S. KLEINER AND S. J. MELTZER: *Retention in the Circulation of Injected Dextrose in Depancreatized Animals and the Effect of an Intravenous Injection of an Emulsion of Pancreas upon this Retention*. Preliminary communication. Presented by S. J. MELTZER.

When dextrose is injected intravenously into normal animals, even in large quantities, it disappears rapidly from the circulation, and the sugar content of the blood is, in a short time, quite normal again. In previous investigations the authors found that in depancreatized dogs there is a tendency for the circulation to retain for a longer period a part of the injected dextrose. In recent experiments it was further found that, when with the infusion of dextrose in depancreatized dogs an emulsion of pancreas is simultaneously injected, the circulation seems to lose its power to retain the injected dextrose. These experiments seem, therefore, to show that the power of the circulation to rid itself of a surplus of sugar is due to the influence of an internal secretion of the pancreas.

R. A. MILLIKAN: *Atomism in Modern Physics*.

Atomism in modern physics begins with Dalton's discovery in 1803 of exact multiple relationships between the combining powers of the elements. Out of this discovery grew the whole of modern chemistry. The second tremendously important step was taken in 1815 when Prout pointed out that the atomic weights of the lighter elements appeared to be exact multiples of that of hydrogen, thus suggesting that hydrogen was itself the primordial element. The periodic table of Mendeleef added support to such a point of view, and Moseley's recent brilliant discovery through the study of X-ray spectra of a new series of multiple relationships, represented by a consecutive series of atomic numbers from 13 up to 79 with every number except three corresponding to a known element, is another most significant bit of evidence. When we add to this three other facts, namely, (1) that each member of a radioactive family, like the uranium family, has been definitely shown to be produced from its immediate ancestor by the loss

by that ancestor of one atom of helium (which is almost equal in weight to four atoms of hydrogen), (2) that in an atomic weight table the differences between the weights of adjacent elements are in almost every case exact multiples of the weight of the hydrogen atom, the characteristic helium difference 4 appearing with extraordinary frequency, and (3) the fact that the introduction of the concept of electro-magnetic mass, and the consequent discovery of the inconstancy of mass, open several ways of explaining the slight departures in the exactness of the multiple relations between atomic weights pointed out by Prout, it will be evident that modern science may well feel fairly confident that it has indeed found in hydrogen the primordial atom which enters into the structure of all the elements. All this is merely a very modern verification of very ancient points of view.

But modern physics has recently taken a more significant and more fundamental step than this, for it has looked inside the atom with the aid of X-rays and other ionizing agents, and has there come upon electrically charged bodies, whose inertia or mass is wholly accounted for, at least in the case of the negative elements, by their charges. This discovery marks the fusing into one another of two streams of physical investigation, namely, the molecular stream and the electrical stream. A necessary condition for the justification of this last step was the bringing forward of indubitable proof that the thing which has heretofore been called electricity is after all, contrary to Maxwell's view, a definite material substance in the sense that it exists in every charge in the form of discrete elements; in other words, that it too like matter is atomic or granular in structure. Such proof was found in the discovery in the oil drop experiments of even more exact multiple relationships between all the possible charges which can be put on a given body than Dalton had ever discovered between combining powers or Prout between atomic weights or Moseley between X-ray frequencies. The greatest common divisor of this series of charges is then the ultimate unit or atom of electricity which has been named the "electron." New evidence that it is indeed a universal and invariable natural constant will be brought forward and a new determination of its value will be presented.

It is obvious that as soon as we could assert that these electrons are found in the hydrogen atom it was necessary to suppose that a single hydrogen atom contains at least two such electrons, one positive and one negative, and as a matter of

fact the evidence is now strong that it consists of exactly two. This twentieth century has then discovered for the first time a new subatomic world of electrons, the constituents of atoms.

All this is definite and probably permanent. But atomic conceptions in more or less vague form have also begun to invade the one remaining field of physical investigation, namely, the field of ethereal radiations. The most significant of recently discovered facts in the domain of radiant energy are these:

(1) Ethereal radiations when absorbed by matter, if they are of high enough frequency, will detach one and only one electron from a single atom. (2) The energy transferred to this electron from the ether wave is independent of the intensity of the incident radiation. (3) It is also independent of the kind of matter from which the electron is taken, but (4) it is exactly proportional to the frequency of the ether wave which detaches it.

These facts are stated in an equation set up tentatively by Einstein in 1905, and arrived at by him from the standpoint of a modified corpuscular theory of radiation. New proofs of the exactness of Einstein's equation will be presented and the evidence for and against Einstein's conception will be discussed. Whether the conception ultimately stands or falls, it appears probable, at any rate, that an equation has been obtained which is to be of no less importance in future physics than Maxwell's equation of the electro-magnetic field, and which seems destined to unlock for the physicists of the future the doors to the understanding of the relations existing between matter and radiant energy.

W. M. DAVIS: *Problems Associated with the Origin of Coral Reefs suggested by a Shaler Memorial Study of the Reefs of the Fiji, New Caledonia, Loyalty Islands, New Hebrides, Queensland and the Society Islands.* (Illustrated.)

The sea-level coral reefs of the Pacific are singularly non-committal as to their origin. The visible reefs accommodate themselves indifferently to any one of the eight or nine theories invented for their explanation. Hence a choice among the theories must be guided not so much by a study of the reefs themselves as by a study of associated phenomena, which thus gain an unexpected importance in coral reef investigation. It is because the associated phenomena have been insufficiently studied that so many contradictory theories have found favor. Of all associated phenomena, those provided by the central islands within barrier reefs are the most accessible and the least equivocal;

next in importance are those offered by uplifted and dissected reefs. It will be shown by means of landscape views and theoretical diagrams that no theory accounts for all the facts—those of the associated phenomena as well as those of sea-level reefs—so well as Darwin's original theory of subsidence; and that the strongest confirmation of Darwin's theory is given by the embayments of the central islands within barrier reefs, as was long ago pointed out by Dana. Thus the results now reached regarding the reefs of the Pacific agree with the conclusions announced in recent years by several Australasian observers. It is believed that the several alternative theories advocated by various investigators during the last thirty-five years will be given up, and that Darwin's theory of subsidence will regain the general acceptance that it formerly enjoyed (1840-80).

GEORGE E. HALE: *Some Vortex Experiments on the Motion of Sun-spots.*

A closely wound helix of brass wire, with circular disks threaded on it, is hung vertically in water and spun at high velocity. The columnar vortex thus formed gradually changes into a semi-circular vortex ring, by the rise of the lower end of the helix until it meets the surface. Thus the second sun-spot in a typical bipolar group might be formed by the turning up of the columnar vortex assumed to constitute a single spot. Preliminary rotation of the whole mass of liquid retards or prevents the turning up process if in the same direction as that of the helix, and hastens it if in the opposite direction. Hence, a persistent single spot may represent a rotating gaseous column whose diameter is large in comparison with its length.

Circular or semicircular vortices have a proper motion at right angles to their planes, in the direction of motion of the inner edge of the whirling ring. As high and low latitude bipolar spots rotate in opposite directions, they should, therefore, move toward the pole and the equator, respectively. Carrington's observations show this to be the case. The velocity to be expected is being determined by measuring the velocity of vortex rings in liquids and compressed gases. Observations of the stream-lines of ionized smoke particles, above single and double magnetic vortices representing sun-spots, are also in progress.

F. W. CLARKE: *The Inorganic Constituents of Marine Invertebrates.*

Essentially a report of progress. The object of the investigation is to determine, more systematically than has been done hitherto, just what each

group of organisms contributes to the marine sediments, and therefore to the formation of marine limestones and especially to their magnesian and phosphatic varieties. The work is practically complete as regards the true corals, the mollusks, the brachiopods and the echinoderms. The inorganic constituents of the corals and mollusks are mainly calcium carbonate, with insignificant impurities. The echinoderms are all more or less magnesian, their skeletons containing from 6 to 14 per cent. of magnesium carbonate. The brachiopods fall into two groups, the shells of one group being mainly calcium carbonate with little organic matter; while those of the other group are essentially calcium phosphate with much organic matter. Work is yet to be done on the foraminifera, the coralline hydrozoans, the bryozoans, sponges and crustaceans. Some of the results so far obtained are novel, others merely confirm the older recorded observations.

CHARLES A. DAVIS: *On the Fossil Algae of the Petroleum-yielding Shales of the Green River Formation.*

The Green River shales of Eocene age are known from northwestern Colorado, west into Utah and north into Wyoming. In places they are more than 3,000 feet thick. They are usually hard, tough, compact and fine-grained and brown in color, but weather to light gray or whitish. Certain beds are highly carbonaceous, burn freely and appear like lignite. Freshly broken surfaces give off a bituminous odor but never appear oily; when heated in closed retorts, petroleum comes off among the distillates.

By special treatment this shale has been sectioned to any desired thinness with a microtome. Microscopic examination of such sections from samples yielding abundant petroleum on distillation, shows the shale to be composed largely of organic matter, chiefly of vegetable origin, as well-preserved plant remains are common.

The most conspicuous plants observed are microscopic algae, which are very numerous in the slides so far studied.

The discovery of a very considerable algal flora in this great and but slightly altered series of petroleum-yielding shales is of especial interest because of the light it may throw on the origin of petroleum and related compounds.

(A few lantern slides from microphotographs of fossil algae from the shales will be shown.)

J. WALTER FEWCKES: *Pictures on Prehistoric Pottery from the Mimbres Valley in New Mexico, and their Relation to those of Casas Grandes.*

The unexpected discovery near Deming, New Mexico, of an exceptionally large number of vessels, made of earthenware, decorated with paintings of mythic animals and men, has led to an enlarged knowledge of the prehistoric culture of our southwest. These pictures, unknown a year ago, have been found in great abundance, and are highly characteristic. Those representing men engaged in various occupations are particularly valuable in the light they throw on ancient manners and customs.

These pictures were painted by a people antedating the nomads found in the Mimbres Valley by the first white visitors, and who disappeared before the beginning of the historic epoch. The pictures have archaic characteristics that point to a remote antiquity as compared to that on modern pueblo pottery.

The cause of the disappearance of this culture from the Mimbres Valley can be traced to local influences rather than to widespread modifications of climate. One of the important local causes of the abandonment of the prehistoric settlements when they were found, was a change in the course of the river.

The geographic isolation of the Mimbres Valley has played an important rôle in developing the peculiar culture these pictures express, while its north and south extension has facilitated interchanges of cultures leading to far-reaching resemblances in these directions.

C. B. DAVENPORT: *Inheritance of Huntington's Chorea.*

Huntington's chorea is a name applied to a group of symptoms first brought together as an entity by Dr. George S. Huntington. The traits involved are four: (1) persistent tremors over a less or greater part of the body; (2) their onset in middle or late life; (3) their progressive nature, and (4) a progressive mental deterioration. Analysis of many chorea-bearing fraternities shows that this supposed neuropathic entity is really only a syndrome inasmuch as, in the choreic families, mental deterioration may appear without tremors, the tremors may progress without mental symptoms, the mental symptoms may not progress and the onset of the disease may be in early life. Indeed, an analysis of families reveals the presence of biotypes characterized by specific forms of choreic involvement and progression. In the inheritance of the elements of the syndrome the choreic movements are clearly a dominant trait; some of the elements of the mental condition (which is usually allied to manic-depressive insanity) are also dominant. The law of anticipation in successive generations

in the age of onset is shown probably to have a merely statistical significance.

C. B. DAVENPORT: *Inheritance of Temperament.*

An analysis of matings between persons who have a prevaillingly elated and those who have a prevaillingly depressed temperament indicates that the temperament of the former is inherited as a simple dominant, that of the latter as a recessive, but not allelomorphic to elation. In F₂ and later generations the zygotic combinations are complex, including elated, depressed, alternating, normal and intermediate grades. Thus with a knowledge of ancestry sufficient to infer the gametic composition of the parents the distribution of temperaments for the offspring may, within limits, be predicted.

G. H. PARKER: *The Fur-seal Herd of the Pribilof Islands.*

The Alaskan fur-seals are pelagic animals that, during the summer, come ashore on the Pribilof Island for the purpose of breeding. The adult males, or bulls, arrive on the islands in May and June followed by the females, or cows. A bull may have associated with him from one to over a hundred cows, and this assembly constitutes a harem. Each cow, shortly after her arrival, gives birth to one young seal, or pup, and soon thereafter becomes again pregnant. The period of gestation is a little less than a year. The seals in the main leave the islands for the open sea early in the autumn. In 1914 there were born on the Pribilof Island over 93,000 seals and the total herd was estimated to be slightly under 300,000, a fair increase over the former year. As there are about equal numbers of males and females born and as the average harem is composed of one male and about sixty females, there are under normal conditions a considerable number of excess males, the so-called idle bulls. The number of idle bulls is a measure of the lack of adaptation in the proportion of sexes and indicative of a certain inefficiency on the part of nature.

ARTHUR L. DAY,
Home Secretary

SMITHSONIAN INSTITUTION,
WASHINGTON, D. C.

EBERHARD FRAAS

FROM Stuttgart comes the very sad news of the death upon March sixth of the very distinguished paleontologist, Dr. Eberhard Fraas, professor in the university and head of the

Royal Museum of Natural History. On the very day following, namely, March 7, the widow of Professor Fraas learned of the death of their only son, Hans Oscar Fraas, in the Argonne near Vauquois, on March 1. The young man was twenty-two years of age.

Eberhard Fraas was one of the most talented pupils of Karl von Zittel, at Munich, and was one of the ablest and broadest of the vertebrate paleontologists of Europe. Besides his explorations, chiefly in the marine and terrestrial Trias and Upper Permian of Württemberg, he traveled widely through other parts of Europe, and made an extensive journey accompanied by the writer through the Jurassic-Cretaceous exposures of the Rocky Mountain region. It was, however, his journey to the dinosaur beds of German East Africa some years ago which very seriously impaired his health and necessitated one or two surgical operations from which he never fully recovered, so that although a man of superb physique his death came at the early age of fifty-two.

He leaves as his monument great collections of vertebrate fossils, especially in the museum at Stuttgart, including the phytosaurs and carnivorous dinosaurs of the Trias and many of the very early and most rare of the Testudinata besides a superb collection of ichthyosaurs from Holzmaden, which he was the first to describe, and of the marine Crocodilia from the Jura.

Among the most important of his early contributions were those to the Labyrinthodonts and other giant Stegocephalia of the Permian. Among his latest was the description of the carnivorous dinosaurs of the Trias as well as the geological narrative of the journey to East Africa. All his papers are enlivened by a keen appreciation of the importance of adaptation and of the adaptive significance of the various types of structure, one of his principal contributions in this line being his interpretation of the adaptive evolution of the ichthyosaurs from terrestrial to aquatic life, which was facilitated by the study of his unrivaled collections.

His death is a loss not only to the Fatherland but to the whole world of vertebrate pale-

ontology, for he was one of the most active and honored members of the new Society of Paleontologists which was recently formed in Germany.

His nature was most genial and those who had the privilege of journeying with him in the field will most keenly sorrow over his untimely death.

To the widow who is suffering this sudden and double bereavement all the friends and admirers of Eberhard Fraas in this country will extend their most heartfelt sympathy.

HENRY FAIRFIELD OSBORN

AMERICAN MUSEUM OF NATURAL HISTORY,
April 5, 1915

THE ROCKEFELLER FOUNDATION AND GENERAL GORGAS¹

THE Rockefeller Foundation has invited General Gorgas to become a permanent member of its staff in the capacity of general adviser in matters relating to public sanitation and the control of epidemics. The trustees of the foundation have for some time been aware of General Gorgas's strong belief in the feasibility of completely eradicating yellow fever from the face of the earth.

During the two years of the foundation's existence the attention of the trustees has been chiefly given to problems of public health, including the control of epidemics and the need of a competent adviser and executive in this field has been strongly felt. When in cooperation with the American Red Cross the foundation undertook the important task of helping the Serbian government to control the epidemic of typhus and the threatened epidemic of cholera the trustees again naturally thought of General Gorgas as a man preeminently fit to be of service in this emergency, and at a meeting held in New York last week they decided to make him a definite offer. This offer is now taken under consideration, and he will doubtless communicate his decision within a few days.

The Foundation's invitation contemplates his retiring from active service, as he is now

entitled to at any time, but it does not contemplate his resignation from the army unless he should be assigned to duties of such a nature as to be incompatible with the regulations affecting retired officers. Such a duty would be involved in his going to Serbia at the present time, which he could do as a representative of the Rockefeller Foundation, but not as an officer on the retired list of the army. The sanitary commission of the American Red Cross has actually been sent to Serbia in charge of Dr. Richard P. Strong, of the Harvard Medical School, as director. The Rockefeller Foundation is cooperating with the American Red Cross in the support of this expedition, and if General Gorgas should accept the Foundation's offer he will doubtless be largely influential in determining the nature and extent of its participation in the work.

In justice to General Gorgas, it should be stated that there is no foundation whatever for the statement that he is to receive a salary of \$50,000. The offer of the Rockefeller Foundation includes a moderate salary and the assurance of the usual allowance in the event of resignation or death. If the offer proves attractive to General Gorgas it will be because of his sympathy with the general aims of the foundation in regard to public health and his belief that the resources placed at his disposal will enable him to render a large service to humanity along the lines of his professional experience and ambition.

SCIENTIFIC NOTES AND NEWS

At the meeting of the American Philosophical Society, to be held at Philadelphia on April 22, 23 and 24, a long and important program of scientific papers will be presented. An account of the meeting, with abstracts of the papers, will be published in *SCIENCE*.

A TESTIMONIAL banquet will be tendered Dr. Abraham Jacobi by the medical profession, his friends and admirers, under the auspices of the Bronx Hospital and Dispensary, on May 6, at the Hotel Astor, on the occasion of the eighty-fifth anniversary of his birth.

THE honorary freedom of the Apothecaries' Company, London, has been conferred upon

¹ A statement made by Mr. Jerome D. Greene, secretary of the foundation.

Sir Ronald Ross, in recognition of the services rendered by him to medical science, especially in the prevention of tropical disease.

THE M. Salomonsen prize of about \$200, awarded every fifth year at Copenhagen for some notable progress in the medical sciences, has this year been awarded to J. Fibiger for his work, "Animal-parasite Cancer in Rat Stomach."

At the annual meeting of the Chemical Society, held on March 25, in London, the new officers elected were: *President*, Dr. Alexander Scott; *Vice-Presidents*, Professor F. R. Japp and Professor R. Threlfall; *Treasurer*, Dr. M. O. Forster; *Ordinary Members of Council*, Mr. D. L. Chapman, Professor F. G. Donnan, Mr. W. Macnab and Dr. J. F. Thorpe.

DR. EILHARD SCHULTZE, professor of zoology at Berlin, celebrated his seventy-fifth birthday on March 22.

PROFESSOR HIRSCHWALD, head of the department of geology and mineralogy in the Berlin Technical School, has been given the degree of doctor of engineering by the Technical School at Dantzig, on the occasion of his seventieth birthday.

REINHARD A. WETZEL, of the College of the City of New York, has been elected a member of the Deutsche Physikalische Gesellschaft, Berlin.

DR. CORNELIUS WILLIAMS, of St. Paul, has been appointed president of the newly established Minnesota State Health Bureau, and Dr. H. W. Hill, of Minneapolis, secretary.

THE Japanese government has applied to the Wistar Institute for the privilege of sending one of its medical officers to the institute to study neurology under Professor Donaldson.

DR. F. KØLPIN RAVN, professor of plant pathology at the Royal Landbohøjskolen, Copenhagen, Denmark, will come to this country during the first week in May and engage in a series of conferences with officials of the United States Department of Agriculture and of state experiment stations in the various states on problems concerned with cereal cultivation, particularly cereal diseases. He will

be accompanied during his entire itinerary by one or more of the following men of the Office of Cereal Investigation: M. A. Carleton, C. E. Leighty, H. V. Harlan and H. B. Humphrey.

THE Royal Geographical Society's awards for 1915 have been made by the council and will be presented at the anniversary meeting on May 17. The Founder's Medal has been awarded to Sir Douglas Mawson for his conduct of the Australian Antarctic Expedition of 1911-14, which has achieved highly important results in several departments of science. The Patron's Medal has been awarded to Dr. Filippo de Filippi for his great expedition to the Karakoram and Eastern Turkestan in 1913-14. The Victoria Research Medal has been conferred upon Dr. Hugh Robert Mill, who for many years has done a great deal on behalf of geographical research. Other awards have been decided as follows: Murchison Award to Captain J. K. Davis, who commanded the S.Y. *Aurora* during the time of the Australian Antarctic Expedition, when he proved to be a seaman and commander of exceptional merit. Back Grant to Mr. O. W. Hobley, C.M.G., for his valuable contributions to the geology and ethnology of British East Africa. Cuthbert Peek Grant to Mr. A. Grant Ogilvie for the good work he has already done in geographical investigation and research. Gill Memorial to Colonel Hon. C. G. Bruce, M.V.O., who for 20 years has been exploring the Himalayas. The following resolution of the council has been accepted by the fellows of the society: "The council, having become aware that Sir Sven Hedin, a subject of a neutral state, has identified himself with the king's enemies by his actions and published statements, orders that his name be removed from the list of honorary corresponding members of the society."

DR. H. D. CURTIS, of the Lick Observatory, lectured before the faculty Science Association of Stanford University, on March 24, on "Some Recent Theories and Developments in Cosmogony."

PROFESSOR R. G. AITKEN, of the Lick Observatory, lectured before the Astronomical

Society of the Pacific in the Cabot Observatory, March 27, on "Globular Star Clusters."

PROFESSOR D. W. JOHNSON, of Columbia University, lectured on the "Physiography of Western Europe as a Factor in the War" before the Rochester Academy of Science on the evening of March 29; before a general convocation of the Case School of Applied Science in Cleveland on March 30; before a similar convocation of the students of Denison University at Granville on March 31; and before the annual meeting of the high school teachers of the state of Michigan at Ann Arbor on April 1.

THE following lectures have been delivered under the auspices of the Syracuse University Chapter of Sigma Xi, during the second semester. On February 5, John A. Matthews, Ph.D., D.Sc., addressed a joint meeting of the Sigma Xi and the Archeological Society of Syracuse, on the subject of "Iron in Antiquity and To-day" and on March 5 Professor H. S. White, of Vassar College, addressed the chapter, students and public, taking as his subject "Mathematics in Nineteenth Century Science."

DR. A. A. W. HUBRECHT, professor of embryology at the University of Utrecht, died on March 21, in his sixty-fourth year.

UNIVERSITY AND EDUCATIONAL NEWS

PRINCETON UNIVERSITY has received from Mrs. William Church Osborn \$125,000 to establish the Dodge professorship of medieval history, and \$100,000 from an anonymous giver to endow a professorship of economics.

THE Schools of Mines, Engineering and Chemistry of Columbia University have received an anonymous gift of \$30,000, to be applied to the reconstruction and new equipment of the laboratories of quantitative, organic and engineering chemistry in Havemeyer Hall. A gift of \$20,000 is announced from Mrs. Samuel W. Bridgham, daughter of the later William C. Schermerhorn, who was a trustee of Columbia University from 1880 to 1903. An anonymous gift of \$4,000 has been made for surgical research in the College of Physicians and Surgeons.

MR. GEORGE W. BRACKENRIDGE has given to the University of Texas his yacht *Navidad*, valued at \$100,000, to be assigned to the biological department of the institution. A preliminary survey of the Texas coast is to be made in the *Navidad*, starting from Port Lavaca.

THE trustees of Emory University, Atlanta, which is being developed under the auspices of the Methodist-Episcopal Church, have agreed to take over the Atlanta Medical College as its medical department. For this department it is proposed that \$250,000 be set aside as an endowment. The trustees have also agreed to erect a new teaching hospital near the medical school, to cost from \$300,000 to \$350,000.

THE University of South Dakota has just completed the erection of a fire-proof chemistry building at a cost of \$100,000. Dr. Alfred N. Cook is head of the department.

THE new buildings of the Washington University Medical School will be dedicated with suitable ceremonies on April 29 and 30. Among those who will deliver addresses are Dr. Eugene L. Opie, dean of the medical school; Dr. William H. Welch, of Johns Hopkins University; President A. L. Lowell, of Harvard University; Dr. William C. Gorgas, surgeon general, United States army; Dr. William T. Porter, Dr. R. J. Perry, Dr. George Dock, Dr. Abraham Flexner and President Henry S. Pritchett, of the Carnegie Foundation for the Advancement of Teaching.

DR. GEORGE HARRISON SHULL, botanical investigator at the Carnegie Station for Experimental Evolution, has been appointed professor of botany and genetics at Princeton University. Steps will be taken immediately to develop gardens, greenhouses and laboratories for his work at Princeton.

DR. RAYMOND G. ORBURN, assistant professor of zoology in Barnard College, Columbia University, has resigned to accept the professorship of biology in the Connecticut College for Women.

DR. B. F. McGRATH has resigned as a member of the staff of the Mayo Clinic, Rochester, Minn., and has accepted the position of di-

rector of the laboratories of pathological and surgical research in Marquette University, Wisconsin.

Dr. HAROLD B. MYERS, Portland, formerly connected with the University and Bellevue Hospital Medical College of New York City, has become professor of materia medica and pharmacology, and Dr. Howard D. Haskins, Cleveland, formerly connected with Western Reserve University School of Medicine, professor of physiologic chemistry at the University of Oregon.

Dr. H. ROY DEAN, professor of pathology in the University of Sheffield since 1912, has been appointed to the chair of pathology and pathological anatomy in the University of Manchester.

DISCUSSION AND CORRESPONDENCE

BOTANY IN AGRICULTURAL COLLEGES

IN SCIENCE for February 5, 1915, Professor C. V. Piper, of the United States Department of Agriculture, calls attention to botany in agricultural colleges. The article referred to directs attention to the previous article by Dr. E. B. Copeland on the same subject in SCIENCE for September 18, 1914. It would seem to be especially true that "this opens up discussion of a many-sided question of high pedagogical importance to agriculture." The articles, referred to above, have presented valuable views and the discussion ought to be continued, perhaps by those more able to do so than the writer. The present is desired to be taken as discussion rather than argument, and certainly not adverse argument.

Dr. Copeland apparently emphasized that "the raising of crops is essentially nothing more or less than applied botany." Professor Piper has forcefully presented the idea that "in striking contrast with chemists, botanists have shrunk from what may be a major application of their science, namely, that of crop production." It would seem that these writers might be on common ground in the belief that the problem of crop production must of necessity be solved with the attention of botanists.

It is possible that the writer may call attention to some difficulties of administration that

are bound to exist in agricultural colleges, so long as the boundary lines are not clear between botany and applied botany and possibly agricultural botany, on the one hand, and agronomy and horticulture on the other.

If it be true, as Dr. Copeland suggests, "the raising of crops is nothing more or less than applied botany," then there is small need for agronomy as a collegiate subject.

If it be true, as per Professor Piper, that the whole field of plant culture, or crop production, being one of plant ecology and plant physiology, must be so recognized by botanists, before progress in crop production will continue, then likewise the future of agronomy, at least the crop side of it, must necessarily trust to the mercy of the conservative botanist.

What is agronomy?

Agronomy is the sum of information or of research directly concerning soils and crops grouped essentially in relation to the business of farming.

Agronomy may be called a science where it is understood that a science is a group of related facts, or, again, it may be called an applied science where it is understood that it has use for many kinds of information which may be drawn from pure science. But any effort to define agronomy as a pure science or to accomplish the work of agronomy by conforming it to any given pure science must result in confusion or in begging the question of agronomy entirely.

It is a perfectly logical question to ask whether agricultural colleges need to recognize any such subject as agronomy. It is perfectly logical to inquire whether the purposes of such colleges may not be better accomplished without any departments of agronomy. It is conceivable that the work of agronomy in all agricultural colleges and experiment stations might be accomplished, or at least attempted, through the efforts of the several departments of pure science, which severally furnish sources of information from which agronomy must constantly draw.

The organization of agronomy as a group of facts in agricultural colleges is thus not absolutely necessary. It is no more absolutely necessary to organize departments of agronomy

omy to conduct instruction and research about soils and crops than it was originally necessary to organize agricultural colleges to educate farmers. The organization of agronomy is arbitrary, just as the entire matter of organizing agricultural colleges was arbitrary. The essential reason why agricultural colleges were organized was that the American people through their Congress conceived the idea that such colleges, if organized, would more definitely solve the problems of farm people and other industrial people than the old forms of colleges already organized. In short, colleges of agriculture and mechanic arts were to be and are logically organized, upon the basis of industrial needs, or else there was not and is not any call for any such separate organizations whatsoever.

It is matter of fact that colleges of agriculture and mechanic arts were and are organized, at least after a fashion, in the several states. Some of them appreciated fully that older institutions were concerning themselves with pure science and had been doing so for a long time and, further, they themselves were not brought into existence to be so many more of the same kind, but rather to make a very direct attack upon the problems of the farm and other industrial life. Those that saw that problem most clearly, it is safe to say, made the best progress.

In such institutions grew and are growing such forms of departments as agronomy, animal husbandry, horticulture, home economics, and dairy husbandry. The unit of every one is an industry, not a science. The organization of every one was necessary to solve the problems of an industry, not essentially the problems of pure science. The people and the departments, for example, who will solve the problems of soils and crops are agronomists and departments of agronomy. They will attack the problems from the standpoint of the business of farming and not from the standpoint of making application of some particular kind of science. It is true that they will need all the accurate information they can acquire from all fundamental sources. Their future departments will embody men whose equipment of knowledge consists in facts neces-

sary to the solving of their peculiar problems. Such equipment of knowledge as they will have, may not make them able to compete with specialists in any given pure science within the field of that science, nor will they expect to. They will have a business of their own. Agronomy can not and does not disregard pure science, but it has not and does not waste much time discussing whether pure scientists need more training. If they do, it is supposed that they will know that much for themselves, and in due time get it. The devotees of pure science will be busy enough withal, looking after their own proper fields of information and research, whether they be botany, chemistry or mathematics.

It is the function of pure science or of the several pure sciences to increase the sum of knowledge. Pure science departments in agricultural colleges are not properly different in that respect from pure science departments anywhere else. If they teach as they must, they should mainly supply that common basis for scientific thought which must needs be the common equipment of all who may engage in any kind of scientific work. If they engage in research, they should continue to develop and enlarge the world's knowledge, with primary regard for knowledge, not its application. In the agricultural colleges, the departments specially organized for the purpose will undertake to make application. Specifically the agronomists of the country are as well prepared to look after this their business of application, as botanists generally are prepared to supply new knowledge.

As Professor Piper has correctly intimated, the business of raising crops has made much progress upon the basis of knowledge secured by agronomists. Strangely enough, some of this knowledge has been "empirical." The process will continue. The way for botanists and botany departments in agricultural colleges to help will be to devote themselves to botany, not agronomy. Perhaps if they do that they will occupy the most enviable positions in the pure science of botany, and bring corresponding honor to their institutions. This will not be possible for them if they fuss around with the business of agronomy.

By such concentration of effort, and by such alone, can the departments of botany in agricultural colleges put themselves in position to answer the demands for botanical knowledge that will be made upon them. By such attention to plants, not as crops and as a part of an industry, but as part of a wide world's life, can they properly supplement the practical knowledge of departments of agronomy. By working separately and together, each in its well-defined sphere, can departments of botany and departments of agronomy in agricultural colleges contribute to the people and to the industry of agriculture, such science and such practise as will entitle their institutions to an honored place in future collegiate life.

SOME NOTES ON ALBINISM

This journal has recently¹ briefly recorded some observation of albinos which recall some chance observations of the writer.

In the late "eighties" or early "nineties" when the English sparrow first became common and abundant near Franklin, Indiana, the writer, as a boy, was much impressed by seeing a white English sparrow. The albino, as well as two or more partial albinos, was repeatedly seen during the latter part of one summer in a large flock of the birds which lived about the barn on the home farm. During the same or a subsequent season there occurred one or more of the partial albinos in a large flock of the sparrows on an adjoining farm. Three or four years ago a female English sparrow pied on one wing and a portion of the back was frequently observed at Cold Spring Harbor.

Within two or three years of the time when the albino English sparrows were seen in Indiana a white fox squirrel was frequently seen in the same neighborhood. The writer saw it only once momentarily and at some distance, but other members of the family saw it and a brother examined it after it was shot by a neighbor. It was white except for the tail, which was characteristically gray. The

¹ O'Gara, January 1; Hargitt, February 12, 1915.

writer is under the impression that he was told that the eyes were "red," but can not vouch for that statement, although it is apparently a fairly safe inference that they were pink.

Near Oswego, Indiana (in 1903 or 1904), was seen an albino robin. It was not a clean white, but was tinged a slightly brownish or dirty hue. The bird was clearly seen at fairly close range and its identification could not have been mistaken.

In 1909 a family of gray squirrels, attracted by the abundant supplies of nuts, etc., proffered them, nested in a tree in the yard near a house in the edge of the town of Marietta, Ohio. One of the squirrels, the male, was a complete albino. Three of the young were albinos and one was a normally pigmented individual. The mother was accidentally killed and the young died. The following season an albino young one was captured and was kept in captivity until maturity. It was a pure albino with white hair and characteristic pink eyes. In all to the present time there are said to have been eleven albino squirrels known in that locality.

In 1907 while collecting the common aquatic isopod, *Asellus communis*, in a spring stream at Arlington, Mass., I found a number of pure albinos. The albinos were fairly abundant, there being perhaps one albino to eight or ten of the normally pigmented individuals. In January, 1910, and again in 1911 albino *Asellus* were found at the same spring.

In a small artificial pond in the Catskill Mountains last October the writer saw what he confidently believes to have been an albino newt, *Diemyctylus viridescens*. The animal was near the edge of the pool and escaped into deep water. It could not be located on subsequent visits to the pond, only a portion of whose margin was readily accessible for observation. The individual was pairing when seen and was apparently a female. There were many newts in the pond, on some of which the black pigment was not very conspicuous, but this one appeared so distinctly a clear uniform light orange yellow that its identification as an albino seemed fairly safe. It appeared very much to resemble in general body color an albinic or xanthic specimen of

the salamander, *Spelerpes bilineatus*, recently kept for several months at this laboratory.

ALBINISM IN THE ENGLISH SPARROW

THE notes on albinism in the English sparrow (*Passer domesticus*) appearing in SCIENCE of January 1 and February 12 suggest the desirability of placing on record certain similar observations made by the present writer. While residing in Chicago, from June, 1904, to May, 1908, I noted English sparrows showing partial albinism in the streets on many occasions. The extent of the white markings on these birds varied from a few feathers to perhaps a third or a fourth of the whole bird, no pure white individual being seen. The striking feature of the occurrence of these white marked birds was their abundance in the late summer and early fall of each year. At that season partial albinos were seen at least several times a week, sometimes daily for three or four days. By early spring these abnormal birds had disappeared; at any rate I have no notes regarding their observation at that time of the year. From these facts it would seem as though the numerous white-spotted birds seen in the fall were immatures of the previous summer. Also for some reason, perhaps connected with their conspicuous appearance, but few of them survived until the beginning of the following breeding season.

The common appearance of partial albinism in the English sparrow in a country where it has been recently introduced through human agency, as compared with the rarity of this phenomenon among most native birds, is suggestive of this being in some way an outcome of unusual conditions surrounding the species in its adopted home. In the absence of data regarding the sparrow in its native land, however, this is mere speculation.

Observations along the same line regarding another species of bird may have some significance. In southern California the Brewer blackbird (*Euphagus cyanocephalus*) has taken most kindly to the altered conditions brought

about by settlement of the country, breeding in the shrubbery of parks and gardens, and feeding on the lawns throughout the towns. In Exposition Park, Los Angeles, the broad stretches of lawn have been particularly attractive to these grackles, and, especially in the fall, they gather here in large flocks. Partial albinism among these birds, just as with the English sparrows seen about Chicago, is of common occurrence in the late summer and fall, on several occasions two or even three white-spotted birds being in sight at the same time. The white areas of the birds observed were always of small size. None of these abnormal individuals has been noted in the spring. The question again suggests itself as to whether these grackles are not affected by something in the altered environment, the changed conditions having been obviously most favorable to the species and conducive to great increase in numbers.

In this connection, however, it is interesting to note that still another bird, the house finch (*Carpodacus mexicanus frontalis*), which has so adapted itself to urban conditions as practically to occupy in the towns of the southwest the position held elsewhere by the English sparrow, in all its vastly increased numbers shows no tendency toward albinism, at any rate no more than any other native bird.

H. S. SWARTH

MUSEUM OF HISTORY, SCIENCE AND ART,
LOS ANGELES, CALIF.

TO THE EDITOR OF SCIENCE: On page 26 of the current volume of SCIENCE Mr. P. J. O'Gara asks for information regarding albinism among English sparrows. I have frequently seen nearly white specimens, especially in New York City, but never any that were entirely white. I believe that albinism occurs more frequently in this species than in any other, because the natural enemies that pick off the conspicuous individuals of other species do not dare to molest the sparrows in their close proximity to man. Thus individuals with albinistic tendencies are enabled to breed and these tendencies are transmitted to their offspring. MAUNSELL SCHIEFFELIN CROSBY

TO THE EDITOR OF SCIENCE: In the issue of SCIENCE for January 1, there is a note by P. J. O'Gara on albinism in the English sparrow. As he asks for further observations I may say that I do not believe partial albinism is at all rare in the English sparrow. Although I have not recently observed any in this part of the country, some years ago, when living in Oregon, I used frequently to see English sparrows that were partial albinos associating with normal members of the same species.

STATE UNIVERSITY,
MINNEAPOLIS, MINN.

WITH reference to Dr. O'Gara's note on the above subject in your issue of January 1, 1915, I may state that in England it is of comparatively common occurrence. Cases are frequently reported in the *Field* newspaper, and I have known of three examples myself. Partially white birds are by no means rare.

I also possess a specimen procured by my brother at Mosul in Asia Minor.

G. BATHURST HONY

4 BEAUFORT ROAD,
CLIFTON, BRISTOL, ENGLAND

TO THE EDITOR OF SCIENCE: In your issue of January 1, Dr. P. J. O'Gara, of Salt Lake City, Utah, states that on several occasions last summer he saw a single female English sparrow (*Passer domesticus*) in the busy streets of Salt Lake City with a pure white plumage. He had never seen any reference to albinism in the English sparrow, and he asks if other observers have found this character to be common in that bird.

In reply, I may say that albino sparrows are fairly frequently seen in different parts of New Zealand. I have about 600 correspondents in the domain who send me notes on natural history, and I have received from them about a score of albino sparrows. These birds were first introduced into New Zealand in 1807, and now are the worst of all the bird pests. Albinism also is not unusual in the English blackbird (*Turdus merula*) in New

Zealand; several complete albinos have been reported to me.

It is interesting to note that our native birds show a very marked tendency towards albinism. There are few species of native birds that do not show this tendency. It is very noticeable in the Kiwi (*Apteryx*), whose soft, fluffy plumage, when pure white, is surpassingly beautiful. Our native birds also have a tendency towards melanism, but this is not so marked as the albinistic characteristic.

QUOTATIONS

AN ATTACK ON THE HEALTH LAW OF NEW YORK STATE

LAST week we commented briefly upon the first annual report of the New York State Public Health Council, congratulating our fellow citizens upon the results of the council's activities and upon the framing of a new sanitary code for the state. And even as we were penning the lines several bills were being introduced into the state legislature which, if adopted, would seriously cripple the work of the commissioner of health and nullify the new sanitary code.

These bills, fathered by Assemblyman Hinman of Albany, five in number, are in the shape of amendments to the public health law. The first (Int. 1561) is directed against the commissioner of health and instead of the present injunction that he "shall not engage in any occupation which would conflict with the performance of his official duties," orders that he "shall devote his entire time to the duties of his office." This is perhaps the least objectionable of the proposed amendments, apart from the insulting innuendo concealed in it, for the duties of the commissioner of health are so exacting as practically to demand his entire time in any case. The second bill (Int. 1600) will, if it becomes a law, seriously interfere with the sanitary work in the state, for it reduces the number of sanitary districts from a minimum of twenty to a maximum of ten, and at the same time fixes the salary of the sanitary supervisor of each district at a maximum of \$2,500. In other words, it doubles

the labors of the sanitary supervisor and reduces his salary about 20 per cent. The third amendment (Int. 1601) makes permissive, instead of mandatory, the establishment of divisions in the State Department of Health and gives the commissioner the power to increase or decrease the number of these divisions, to consolidate them, or to change the name of any division at his pleasure. This is an altogether unnecessary interference with the existing law, and if it had any effect it would be in the line of decreased efficiency as making the divisions impermanent and liable to change at the whim of any one in power for the time being. The fourth amendment (Int. 1602) strips the Public Health Council of its power to define the qualifications of directors of divisions, sanitary supervisors, local health officers, and public health nurses hereafter appointed. The introducer's object in this amendment is not apparent, but the result of its enactment would inevitably be to open these appointments to unqualified persons and to create a number of jobs to be given in reward for political services. The fifth and worst of this series of bad bills (Int. 1603) would deprive the Public Health Council of the power to establish sanitary regulations, would delegate this to the legislature, and would even abolish the present sanitary code unless it shall be approved by the present legislature—and how much chance it would have of being approved by a legislature which had already adopted these amendments one can well imagine.

These, briefly stated, are the bills by the enactment of which it is proposed to impair the efficiency of the health department and to vitiate the work it has already accomplished. What may be the reason for the introduction of these bills it is difficult to understand. Their passage would not be in the interests of economy, for the worst of them, if passed, would not save the state a dollar, and others would rather increase the expenses of health administration by reducing the efficiency of the department, by putting the formulation of a new code in the hands of inexperienced and of men ignorant of sanitary science, and by opening many of the most responsible positions to

incompetents. No business can save money in that way. The entire appropriation asked for by the health department is only about \$400,000—a paltry sum in comparison with the saving of lives and of dollars as well, which it is certain will result if the present law is let alone.

As a direct result of the work of the department during the past year there are two thousand persons, one thousand of them children, alive to-day in this state, outside of New York City, who would have been in their graves but for the efforts of Dr. Biggs and the Health Council. Are Mr. Hinman and his colleagues in the legislature willing to let these and three or four thousand others (for the life saving in public health work is cumulative) die next year in order to save thirty-five thousand dollars in the salaries of the sanitary supervisors who are to be dropped?

We can not believe the legislature will pass these reactionary amendments or, if it does, that the governor will sign them. But it will be better to spare both the legislature and the governor trouble by killing the bills in committee. This would doubtless be their fate if every physician would at once file his protest with the chairmen of the committees which now have the bills under consideration. In such protest the bills should be referred to by their introductory numbers and the protest should be addressed to the chairman of the respective committee as follows: Introduction Number 1561 (the first one above mentioned), Judiciary Committee, Assemblyman Frank B. Thorn, chairman; Int. 1600, Ways and Means Committee, Assemblyman Alexander Macdonald, chairman; Int. 1601, 1602 and 1603, Public Health Committee, Assemblyman Gilbert T. Seelye, chairman. We need not add that prompt action is needed to save the state from this threatened calamity.—*New York Medical Record*.

SCIENTIFIC BOOKS

Biology. By GARY N. CALKINS, professor of protozoology in Columbia University. New York, Henry Holt & Co. 1914. Pp. i-viii + 241. 101 figures.

This text-book is frankly based upon the well-known earlier work of Sedgwick and Wilson and follows it closely in subject-matter, method and illustrations. It is, however, even more strictly of the informational type and omits all reference to practical exercises or laboratory directions. The physiological side of the subject is emphasized. In the order of treatment the present work departs from the plan of its prototype and substitutes the logical course of proceeding from the simple forms to the complex, for the more practical one of introducing the student to the subject through contact with an organism of such size that it can be studied by the ordinary method of observation. For most teachers this would seem to be a change of doubtful expediency. While the fern and earthworm are still considered at some length, other types (*Amoeba* and other Protozoa, *Hydra*, *Homarus*) receive as much attention. In each case, however, the particular form is studied in connection with some biological principle which it illustrates. The amoeba typifies the activities of one-celled animals; hydra, the nature of animals with tissues; the earthworm, the conditions developing where organ systems are present; the lobster, a more complex condition of organ systems involving the subject of homology. More briefly the nature of one-celled plants is treated in connection with yeast and bacteria; parasitism, as exhibited by *Tenia*, is discussed; and animal associations, adaptations against parasites, and the mechanism of immunity are appropriately presented. A series of these general subjects, including animal descent, evolution, conformity to type, somatic and germ plasm, and Mendelism, appears in the last chapter of the book, wherein the most recent work receives attention.

General biology is defined by the author as the science which deals with "the fundamental principles of living matter" and he then outlines specifically seven subdivisions which embrace practically the entire realms of morphology and physiology. That the recognition of such a subject as general biology is purely a matter of expediency is admitted when the author states that a thorough study of any one of the seven topics would compass

the whole field. The purpose of general biology is, however, conceived to be that of forming a foundation upon which the other more specific subjects can be built. It is the thought of the author, and of others who write similar books, that students can be made acquainted with the main biological conceptions through a course designed for this specific purpose instead of acquiring the knowledge as a result of personal experience with many animals and plants. The large results of biological research are presented to the beginner before he is much acquainted with the varied materials manifesting the properties of living matter.

Whether this method is the best for use with an elementary class in the freshman or sophomore year of a college course is open to question. Much depends upon the circumstances in each institution. It may be said, in a general way, that the observational sciences won a place for themselves in the curriculum because they promised a training, through personal experience, that could not be obtained in subjects which are studied merely from books. Information comes thus as a result of discovery, and with knowledge comes training. Not only are facts gained but the method of their acquisition appears through repeated experience with concrete examples. The student is not told that the lobster has twenty somites in its body, but he is asked to discover for himself the number present in a certain specimen. He is not offered the generalization that all normal lobsters have the same number, but he is led to form this conclusion himself through opportunities for comparison with other representatives of the species and by means of the collective experiences of his fellow students. He is not told that there is a large group of branchiate arthropods characterized by this fundamental organization, but he is guided to the formation of such a conception by the observation that a considerable number of such animals, although differing in many other ways, presents a repetition of the same numerical condition. Experience, not authority, is the guide; the goal is a development of the power of accurate observation and the formation of judgments based upon such observations, not the acquisition of cer-

tain facts relating to a group of objects, known as plants and animals, as distinguished from other facts relating to non-living objects, or from still other facts concerning human activities in methods of expression or of living. The path of each student in his approach to this goal is his own, and it varies in infinite degrees from all others—no beaten track of conformity to text assures his arrival.

"But hold!" says the efficiency expert of the curriculum makers, "Will the student learn all about plants and animals in the course in biology, will he be able to identify and name those forms he comes in contact with, will he know about the nature of his own body and of his relation to other animals? We want the student thoroughly grounded in the principles of biology, so make a book and teach him these things. For this purpose you may have him for one twenty-fifth of his college course." And so there is much writing of books and the puzzled teacher tries first one and then the other. Something is the matter with each one, so finally he makes a book of his own. If he has decided that the efficiency expert of the curriculum makers is right and that a certain group of facts, presented to the students for their acceptance or rejection is the proper content of a course he emerges from his trials very comfortably and, educationally, lives happily ever after.

Of the numerous efforts to supply the demand for text-books which shall inform students regarding the principles of biology, that of Calkins is one of the most satisfactory. Doubtless, in his own laboratory, the book occupies a proper place in relation to the individual work of the student; but it probably would not be far from the truth to assume that, even under these favorable conditions, the element of individual effort is small. In the hands of the dependent teacher even this remnant would disappear. When a descriptive text is used it results, under the best conditions of laboratory work, in confirmation by the student of facts studied in the book; in the absence of proper laboratory opportunities the course based upon it becomes merely another informational subject and the test of its accomplishment purely one of memory.

The distinction between the observational sciences and languages, history and other subjects presented on the basis of authority, largely disappears in the former alternative and entirely so in the latter. Undoubtedly the subject-matter of biology would well warrant its inclusion in a college course, but in the face of the opportunities for training students in making accurate observations, forming independent judgments and developing logical habits of thought—qualities that are always so much needed—how poor is the return! It is not to be denied that it is easier to inform students than it is to train them; it is not to be denied that there is a large popular demand that schools should instruct their students upon matters which will be of immediate "practical" use to them later. But it is the duty of schools to recognize that real education is training, and so to devise and administer their curricula as to provide this training, to the best advantage, for the various types of mind that are to be educated. In furthering this purpose the subject of biology offers unique and valuable opportunities to develop the powers of observation, comparison and judgment through personal experience with the scientific method. In view of the great significance of this method in our past achievements, and of its promise for the future betterment of society, it is incumbent upon teachers of those subjects, in which it is best emphasized, to insist that they be given time and opportunity to teach in ways calculated to render effective, to the largest degree, its operation in the activities of their students.

C. E. McCLUNG

An Introduction to the Study of Fossils (Plants and Animals). By HERVEY WOODBURN SHIMER. New York, The Macmillan Co. 1914.

In most sciences it is a remarkable year which does not produce at least one text-book, but paleontology has been taught in this country for eighty years before the appearance of this, the first strictly American elementary text-book of paleontology. Amos Eaton seems to have been the first American teacher to

present this subject to students, and, as a teacher, is only the grandfather or great-grandfather of the present generation, for James Hall was his pupil, and it is well known how many owe their training directly or indirectly to him. It is probable that few of the American paleontologists, excepting those who have graduated since 1900, received any formal instruction in paleontology, the general method being to set before the pupil a tray of fossils and the "Paleontology of New York," and await the, sometimes tardy, results of self-development. This meant, of course, a very long period of training, and the consequent discouragement of many who might otherwise have pursued the subject. This somewhat haphazard method was due, I believe, largely to the absence of any suitable text-book. These remarks do not, of course, refer to the vertebrate paleontologists who have in the main been zoologists, and who trace a very different and by no means parallel line of descent.

English text-books have been available and used to some extent. First Nicholson (1872, then at Toronto), later Nicholson and Lydecker (1889) were used, but these books were too compendious for introductory work, and have now long been out of date. Next came Wood's excellent little book (1893), now in its fourth edition, but this text covered only invertebrate paleontology and is much better adapted for the use of students in England than those in America. Finally came the English revision of Zittel's text-book (1900, 2d ed., 1913), which, though really a reference book, has been the background of the modern teaching of the subject in America. This book, valuable as it is, can not be placed in the hands of beginners, and all teachers will welcome the appearance of the present volume, a book which has been definitely planned to meet the needs of the novice, and which covers, in an elementary way, all branches of the subject.

The introduction of 28 pages is devoted largely to an excellent discussion of fossils and states of preservation. Personally, the reviewer regrets the appearance of the words fossilization and fossilized in this chapter. While these terms may be logically defined, they are seldom logically used, and, once set

before a student, no amount of warning will prevent his use of them in a sense implying some alteration of the original substance.

Pages 29 to 82 contain a brief presentation of some of the more important facts concerning fossil plants. It would manifestly be impossible to write, in 55 pages, an introduction to the study of paleobotany, but the author has made a wise choice of the points of more general interest and includes as much as it is possible to use in an ordinary introductory course in paleontology.

The Invertebrata occupy pages 83 to 320. In this part of the book the author follows uniformly the plan of presenting first a somewhat complete description of a typical, if possible, modern, example of each important group, describing the morphology, physiology, and to some extent the habits of the particular animal discussed. Thus, under the protozoa, *Amoeba proteus* is described as a type of the phylum, while at the other end of the section, in the phylum Arthropoda, *Cambarus* is described as a type of the class Crustacea, and *Triarthrus* as a type of the subclass Trilobita. Following the description of the type comes a general discussion of the group, relating particularly to those members found as fossils, and finally a brief description of some of the more important genera. Some paleontologists will doubtless criticize the amount of space devoted to the morphology and particularly the physiology of modern forms, but those of us who have to teach know that students rarely come to us with the kind of zoological training which would best fit them to take up paleontology, and to have in one book the zoology and paleontology will be of the utmost use to us.

Pages 321 to 402 contain the description of the Chordata, the cat being taken as a type of the Vertebrata. This part of the book is necessarily, from its briefness, somewhat less technical than the preceding part, but gives a good résumé of the important structural features of the various groups of vertebrates, and of the phylogenies of several families. It is usually found that this part of the subject is of much greater interest to the student and general public than any other part, and it is

to be regretted that the limits of the book did not allow a somewhat more expanded treatment, especially of the Reptilia and Primates.

On pages 403 to 406 one finds a brief bibliography of some of the more important books on subjects treated in the volume, and then follow three pages giving in tabular form the geological time scale and the geological ranges of the principal classes of plants and animals. The remaining 39 pages are devoted to an unusually full index and glossary.

The illustrations in the book deserve special mention. They are very numerous, and an unusually large number are original or redrawn for this work, and all are remarkably clear, well executed, and well reproduced. The figures of the echinoid, pages 187 and 188, may be particularly noted for their delicacy and clearness. Altogether the illustrations are better than those usually found in an elementary text-book.

A very useful feature is the practice throughout the book of giving the derivation of the generic and other group names. The questions, designed to direct laboratory work in connection with the text, will be of more or less value, according to the individual teacher. They serve as a review for the reader and draw attention to the important points in the descriptions. The book is of convenient size, the type good, and though certain paragraphs and the questions are set in another font from the main part of the text, the differences are not so great as to mar the appearance of the page, and are by no means comparable to the "fine print" of a generation ago.

As a text for an introductory course in paleontology the book strikes one as especially well balanced and well done. It will also be found extremely useful to the students of zoology and historical geology, and furnishes us with an answer to the question put so often to a geologist or paleontologist: "Where can I find a book about fossils which I can read without first studying paleontology!"

This review is not meant either as a eulogy or as a criticism of the book in hand, but the writer is aware that the text does contain some small slips, of the kind so peculiarly annoying to the author, but so difficult to detect in proof-

reading. Most of these are small things which are either so obvious as to be without danger to the student, or things which would be apparent only to the specialist, and may easily be corrected in a later edition. One which might perplex the beginner is on page 352, where the Urodela are called Lizards. The others are almost all in the explanations of the figures.

PERCY E. RAYMOND

HARVARD UNIVERSITY

SPECIAL ARTICLES

ON THE LIFE OF ANIMALS WITH SUPPRESSED KIDNEY FUNCTION

BOTH clinical and laboratory observations agree in demonstrating that many of the so-called consequences of kidney disease are really nothing of the kind, but must be interpreted in some other fashion. Thus, the assumption that the edema sometimes found in patients suffering from kidney disease is the consequence of the disturbed kidney function lacks all support, for patients with complete suppression, or animals from which both kidneys are removed, do not show any consequent edema. In fact, such patients and animals steadily *lose* in weight unless special efforts are made to keep this up. Large, nephrectomized rabbits, for example, will lose some 50 grams per day before they succumb some four to eight days later.

In the same way that clinical experience and experiment have shown that the edema accompanying certain kidney disturbances is not to be regarded as a consequence of the loss of kidney function, they prove also that high blood pressure, cardiac hypertrophy, and the clinical manifestations of headache, stupor, coma, etc., so commonly regarded as "uremic" are not secondary to such loss of kidney function as so widely believed. The fact remains, however, that even though much revision is necessary in our interpretation of the signs and symptoms evidenced by victims of kidney disease, loss of kidney function is commonly regarded as incompatible with any prolonged continuance of life.

Why does man or an animal deprived of his

kidney function die? Since nephrectomized animals regularly show a progressive loss in weight, and since this is, in the main, only water, a first reason for death might reside in the gradual drying-out of the tissues. Whether the animal is fed or whether it is starved, a certain minimum of necessary chemical changes goes on, which continue, as long as the animal remains alive. A second reason for the death of the kidneyless animal resides, therefore, in the accumulation of metabolic products within the organism which normally are thrown off in the urine. A third reason for death (but one for which at present we lack every experimental proof) might reside in the loss of some internal secretion produced by the kidney and necessary for life of the organism as a whole.

The analysis of the conditions necessary for a proper exhibition of kidney activity would seem to indicate that it is the primary function of the kidney to secrete water. It secretes water in proportion to the amount brought it in a free state in the arterial blood stream. As this free water passes down the uriniferous tubules it leaches out of the cells bordering it and constituting the kidney parenchyma the dissolved substances which give urine its distinguishing characteristics (urea, ammonia, creatin, sugar, salts, etc.) which substances originally diffused into the kidney parenchyma from the blood stream.

If we ignore the matter of an internal secretion, these considerations, if correct, compel the conclusion that the kidney is of importance to the animal, first, because it is an organ through which water may be lost when present in amounts over and above those necessary to saturate the tissues (saturate the hydrophilic colloids); and second, because this loss of water makes possible the loss of certain dissolved substances which appear in even normal metabolism.

The steady loss of water in the ill or by a nephrectomized rabbit, for example, need not, of course, be an important element in the causation of death. Care in the administration of water by rectum or subcutaneously can overcome this. Nor is the inability to lose much water quickly, as by the kidney route,

alone an insurmountable cause for death. Even under physiological conditions the human being not only can but does lose more water from the lungs and skin than through the kidneys. What is missing is the possibility of losing along with the water the various dissolved substances which appear as the products of metabolism. If this reasoning is sound it is to be expected that, other things being equal, *animals deprived of their kidney function should live the longer the better the possibilities of securing an adequate loss of dissolved substances along with their water elimination.* The facts bear this out. The furred animals, for example, which lose no water except through the lungs, after the kidneys are removed, survive this operation little more than four to eight days. The human species with its ability to sweat tolerates loss of kidney function some six to twelve days. James Taggart Priestley has reported the case of a patient who lived 23 days with complete suppression of urine. It is considerations of this kind that have prompted clinical workers to resort to sweating and catharsis by way of transferring to the skin and gastro-intestinal tract the functions which are ordinarily subserved by the kidney whenever this organ is pathologically affected. But even when advantage has been taken of such potentialities, the lives of patients with complete loss of urinary function have not been long.

It occurred to me that it ought to be possible to observe a greater span of life in animals after complete suppression of kidney function if only it were possible on the one hand to cover the needs for water absorption and water loss, while on the other, provision were made for an adequate loss of the products of metabolism which normally are leached out by the water which passes through the kidney.

Such conditions are satisfied in the case of the frog. Not only does the frog cover its daily needs for water (saturate its body colloids) by spending a part of its time in the water, but it also loses under the same circumstances the same group of materials which ordinarily give the urine its characteristic composition. The problem is similar to that in man, who loses the same dissolved substances in the sweat that

he loses in the urine, only in less amount. The frog does the whole more easily. When sitting in the water it not only absorbs water to supply its needs, but loses at the same time the non-volatile products of its daily metabolism (these diffuse into the water from the skin exactly as the same substances in the mammal diffuse from the kidney cells into the water running down the uriniferous tubules). As I have so frequently insisted, solutions are not absorbed or secretions given off "as such." While a secretion of water and of dissolved substances may occur in the same direction, they may quite as easily take opposite ones. These considerations make it apparent why on *a priori* grounds alone the frog (and other amphibia) should be able to tolerate a loss of kidney function better than land animals.

Experiment has justified the conclusion. I tried originally to bring proof in this direction by cutting the kidneys out of frogs. The operation is not only difficult, but fails because of the anatomical peculiarities which characterize the circulation in these animals. Since the venous blood returning from the legs passes through the kidneys, their excision is followed by an edema of the hind legs. To escape this effect and yet to exclude the external function of the kidneys, the ureters were therefore tied. Under aseptic precautions a series of frogs were operated upon through the flanks and the ureters isolated. They were tied with a first ligature close to the kidney and with a second as near the bladder as possible, the connecting segment of ureter being cut out. *These animals have now lived since January 8 of this year and are perfectly normal.*

My technical assistant, Josef Kupka, showed me how to keep these animals in excellent condition. They are housed in glass boxes heavily padded with moist moss. Inverted porcelain dishes with side openings permit them to hide. A shallow enamel pan always filled with fresh water is placed at one end of each cage. Every few days the frogs are fed live meal worms, which they devour ravenously. The wounds heal completely two weeks after the operation. At the present writing the animals thus operated are livelier and in better physical condi-

tion than the winter frogs comprising the stock from which they were chosen.

The kidneys of the frog after ureteral ligation seem to suffer but slight if any change. What has been observed will be discussed at another time.

These experiments prove that *frogs may live for weeks after complete suppression of external kidney function.* If the explanation of why this is possible in the frog is accepted as correct, it not only gives scientific support to long-established empirical clinical practices, but emphasizes the importance of a closer analysis of the conditions which may improve qualitatively or quantitatively the matter of absorption and secretion of water and absorption and secretion of food and the products of metabolism through the skin and bowel in the patient suffering from an inadequate kidney function.

EICHBERG LABORATORY OF PHYSIOLOGY,
UNIVERSITY OF CINCINNATI

SOCIETIES AND ACADEMIES

THE CHICAGO ACADEMY OF SCIENCES

THE annual meeting of the Chicago Academy of Sciences, held January 12 at the Academy building in Lincoln Park, Chicago, was an occasion of special interest. The chief speaker was Dr. Albert A. Michelson, of the University of Chicago, who presented in simple, untechnical language the results of his remarkable studies on the rigidity of the earth. Dr. T. C. Chamberlin reviewed the history of the academy during the past eighteen years, during which time he had been president, and the following officers for the coming year were elected:

Professor John M. Coulter, President.
Professor Henry Crew, First Vice-president.
Dr. Stuart Weller, Second Vice-president.
Dr. Wallace W. Atwood, Secretary.
Mr. Henry S. Henschen, Treasurer.

Mr. LaVerne Noyes, president of the board of trustees, spoke encouragingly of the present and future work in the museum. Mr. Noyes is especially interested in the construction of habitat groups illustrating the natural history of Chicago and vicinity, and through his personal supervision and generosity a remarkable series of forty-one new groups was opened for inspection at the close of the business meeting. Dr. Wallace W. Atwood, of Harvard University, who has held the secretaryship of the academy during the last few years, and been associated with the academy boards in the or-

ganization of the museum and in the promotion of educational work, returned to Chicago to address this meeting on the "Progress of the Museum Work during the Past Year."

The "Celestial Sphere," which was recently installed in the Academy building, was open for inspection, and demonstrations were given at frequent intervals. In this apparatus all of the brighter stars which are ever visible from the Chicago region are represented in their appropriate places and with their appropriate magnitudes. By electrical power the sphere is rotated, so that the stars follow precisely similar courses to the apparent motion of the fixed stars in the heavens. In eleven and one half minutes the sphere completes one rotation.

The policy of the museum during the past few years has been to limit its new exhibits to those illustrating the natural history of the Chicago region. Thus the birds, mammals, insects, reptiles and flowers of Chicago and vicinity have been placed on exhibition. Every pains is taken and no expense spared to make these exhibits of the local material just as attractive as any that could be prepared. Each exhibit is arranged to bring out some feature in the life of the animal rather than to display the mounted specimen as dead. Each habitat group is based on field studies; the background is an enlarged and colored photograph taken in the field where the specimens were collected, and the foreground is so constructed that it blends imperceptibly into the painted background. The animals are either at play, in search of food, quarreling, caring for the young, or in course of flight. These exhibits have already proved to be of unusual educational value to the community, and they are being used regularly by the teachers in the public and private schools of Chicago.

The children's science library and free reading room was opened for inspection. About three hundred members and guests were present.

On the evening of January 15, the board of trustees gave a dinner in honor of LaVerne Noyes. This dinner was given as an expression of the hearty good fellowship in the board, and of the sincere appreciation of the generosity of Mr. Noyes in promoting the work of the academy. Mr. Henry B. Henschen presided as toastmaster. Professor T. C. Chamberlin, Professor John M. Coulter, Dr. Frances Dickinson and Dr. Wallace W. Atwood responded to toasts. At the close of the dinner the toastmaster presented a loving cup to Mr. Noyes on behalf of the board of trustees.

THE BIOLOGICAL SOCIETY OF WASHINGTON

THE 537th meeting of the society was held in the Assembly Hall of the Cosmos Club, Saturday, March 6, 1915, called to order by ex-President Stejneger at 8 P.M., with 60 persons present.

Under the heading Brief Notes, Professor A. S. Hitchcock called attention to the plans and methods of work in preparing a new Flora of the District of Columbia. It is hoped it will be completed within a year. It will contain analytical keys of all the higher plants found within a radius of fifteen miles of the city of Washington. It will not contain descriptions.

The first paper of the regular program was by J. W. Gidley, "Notes on the Possible Origin of the Bears." After the examination of much fossil and living material the speaker had arrived at the conclusion that the bears, constituting a small homogeneous, widely distributed group are not closely related to other living Carnivores. From a consideration of the tooth structure, the bones of the feet, and the basal cranial foramina, Mr. Gidley concluded that the bears were probably derived from the *Clanodon* group of the Creodonts, and that other living Carnivores were descended in part at least from the Miacidae, a family of Creodonts not distantly related to the *Clanodon* group.

The second communication was by the sculptor, H. K. Bush-Brown, "The Evolution of the Horse." The speaker was present by special invitation of the president and introduced to the society by ex-President Stejneger. Mr. Bush-Brown discussed briefly the geological evolution of the horse, and then spoke at considerable length on the evolution of modern breeds of horses, particularly of the Arab and the effects of breeding it with other races, and its development in this country. His paper was well illustrated by lantern slides showing anatomical characteristics of various horses, as well as their external appearances.

On Thursday, March 11, 1915, at 8:30 P.M. the Biological Society of Washington held a joint meeting with the Washington Academy of Sciences in the Auditorium of the National Museum. Mr. Wilfred H. Osgood, of the Field Museum of Natural History and a member of the special commission for investigating the fur seal question for the Department of Commerce during the summer of 1914, delivered a lecture illustrated by stereopticon and motion pictures on the fur seals and other animals of the Pribiloff Islands. All phases of the life of the seals on the islands, methods of killing, skinning, salting, etc., and

the introduced herds of reindeer, the Steller's sea-lions, and the native birds were shown in motion. About 350 persons were present.

M. W. LYON, JR.,
Recording Secretary

ANTHROPOLOGICAL SOCIETY OF WASHINGTON

At the 478th meeting of the society held December 1, 1914, in the Public Library, Dr. George S. Duncan delivered an address on "The Sumerian People and their Inscriptions." Their oldest inscriptions antedate 3,000 B.C., and the Enlil temple in Nippur dates back probably to 6,000 B.C. The Semites from Arabia conquered the Sumerians before 2,100 B.C. Of the Sumerian cities, only Lagash and Nippur have been thoroughly excavated. Scholars agree that the Sumerians were neither Semites nor Indo-Europeans, but were probably Mongolians. Their language was agglutinative. Their only garment was a rough woolen skirt. Various cereals were grown; also the date palm. There were many occupations, including weavers, smiths, boat-builders, jewelers and carvers in wood and ivory. There were priests, librarians, notaries, physicians, astronomers and musicians. The country was divided into city states ruled by kings. The age of Gudea, about 2,600 B.C., was one of high artistic development. The chief divinities were Anu, god of the sky, Enlil, god of the earth, and Enki, god of the water. Their religion was nature worship. The inscriptions consist mainly of historical records, laws, contracts, epics and religious texts. The tablets contain the oldest records of a paradise, a fall and a flood.

At the 480th meeting of the society, held January 5, 1915, in the Public Library, Dr. John R. Swanton read a paper on "Ethnologic Factors in International Competition." He showed that the factors which tend to disunion between human societies have been operative in all parts of the world and were probably necessary to the best development of the race. At the same time, the end of warfare may be confidently predicted from the constant increase in size and decrease in number of political units, from the progressive weaving of the world more closely together by means of transportation facilities and other means of communication, and because of the gradual international bankruptcy which war entails. A standing army goes with an aristocratic ruling class. There can be no permanent peace until exploitation of one nation or class by another ends.

At the 481st meeting of the society, held January 19, 1915, Prince Sarath Ghosh delivered an address on "The Ancient Civilization of India." The Aryans settled in India between 6,000 and 4,000 B.C. and there adopted agriculture, the beginning of civilization. Here also man passed from promiscuity to monogamy. The government was first patriarchal, then a republic, then an oligarchy, then a monarchy. With the latter began the caste system. Man first worshipped tools and weapons; later, nature. By 2,500 B.C. the Hindus worshipped a supreme deity and the language in the Vedas had reached its highest perfection. Deity was regarded in its gentler qualities as feminine. With religion began the arts and sciences. The age of life on the earth was estimated at four million years. An exalted code of warfare was evolved. By 600 B.C. Hindu civilization had reached its zenith. The Aryan invaders conquered the Turanian or Dravidian races they found in India and made of them subordinate castes. India taught the arts and religion from Java to Japan.

DANIEL FOLKMAR,
Secretary

ACADEMY OF SCIENCE OF ST. LOUIS

At the meeting of March 15, Professor Nipher gave a brief account of work done in his laboratory. During the summer of 1914 he detected what appeared to be an effect of the fog-horn of a steamer on the magnetic field of the earth.¹ In his recent work a large bar magnet in a room containing an influence machine, and in contact with one terminal, served as a deflecting magnet upon a magnetic needle in an adjoining room. The deflecting effect of this magnet was balanced by another bar magnet, on the opposite side of the needle. The needle was made very sensitive by means of compensating magnets. A musical note from an organ pipe, operated by means of compressed air, produces effects precisely like those attributed to the fog-horn. Here also the effect is superposed on disturbances of the same order of magnitude due to other causes. Professor Nipher remarked that any disturbance of ionized air appears to be the origin of electro-magnetic waves in the ether. When we talk to each other in air ionized by solar radiation, we are perhaps sending wireless messages through the ether of space.

RADIO-ACTIVITY AND THE PERIODIC SYSTEM¹

THE periodic system of the elements has for nearly half a century proved a most puzzling and absorbing problem to chemists. It has been called a law, but while there is undoubtedly an underlying law or laws, I doubt whether we have as yet any very clear conception of them. Certainly, the usual statement that the properties of the elements are periodic functions of their atomic weights was never strictly true, even in days of partial knowledge, and is much less true now. It was neither the periodicity "of the geometers," as Mendeleef himself said, nor the function of the mathematician. Indeed, we have now come to a view where, apparently, we must abandon the atomic weight as the only or even the chief determining variable.

The truth is that for many years after its announcement it was more truly a working hypothesis, and a great deal of work had to be and still has to be done before it can attain to its completed form. It contains much that is true, has been most useful as a guiding principle, and has shown a wonderful power of adjustment to new facts and increasing knowledge.

It was in 1895 that the system had to adjust itself, to the first severe jolt which it received through the discovery of argon and helium, and three years later, of other inactive, monatomic elements. The necessity for readjustment here had been in part foreseen. The abrupt change in the progression of the elements from strongly electro-negative fluorine to strongly electro-

¹ Read before the Elisha Mitchell Scientific Society, March 9, 1915.

positive sodium, and, in general, the transition *per saltum* from period to period had been explained by Reynolds and others. It needed explanation and was impossible mathematically except by passing through zero or infinity. Some, as Sedgwick and de Boisbaudran, seem to have predicted such transition elements, and when argon was discovered it was not difficult for Julius Thomsen and de Boisbaudran to arrange an entire zero group with approximate atomic weights three years before Ramsay's brilliant discovery of the other inactive gases.

There are other anomalies in the system which are difficult to explain with the accepted tabulation. Such, for instance, is the existence of the rare earths, now some sixteen in number, so closely alike chemically and so different from other chemical individuals. The more they are studied, the less possible does it seem to fit them in any vacant places in the table. Meyer has recently suggested that they may form a miniature periodic system in themselves reproducing the relations of the main system. But a more serious breakdown in the supposed fundamental principle of the system comes in the relative position of such elements as argon and potassium, cobalt and nickel, tellurium and iodine. After most exhaustive investigation of their atomic weights it has become evident that these can not be used in deciding the relative order and at the same time have these elements fall into the proper grouping with those elements chemically most nearly related to them. So the order of the atomic weights has been tacitly abandoned and the superior determining power of the chemical characteristics acknowledged. This can only mean that the mass of the atom is not the sole, nor indeed the chief, determining variable, and it would seem that the search for the latter can only be ended by

the solution of the problem as to the nature of the atom itself.

Certain clues to this have undoubtedly been in our hands for a long time, but their leading was not clear and the thought of them baffling. Such, for instance, were the facts that by taking an atom of nitrogen and four of hydrogen a grouping of atoms was obtained which behaved in general as an atom and was the analogue of potassium. Or, again, carbon and nitrogen give us an analogue of chlorine—and so with compound radicals in general. But while both building and tearing down again were easy, they seemed to throw no light on how those we could not tear down were once built up.

Still another thought-inspiring fact which would seem to have important bearing on the nature of the atom and hence the meaning of the periodic system is the ease with which certain elements by a change of valence change their chemical character and form distinctive series of salts as if they had been transformed into different elements. This causes some confusion and what would ordinarily be called forcing in the present tabulation of the system, and it will be recalled that Mendeleeff, in his earlier tables, actually placed certain of the metals, as copper and mercury, in two different groups, assigning each two different places. Signs are seen in the work of Barbieri and others of a tendency to place certain of the elements in two or more different groups according to valence.

I believe that one should keep in mind the idea involved in Patterson-Muir's definition of an element as a collection or group of properties. Thus there are weight, electro-chemical nature, affinity, valence and other properties by which we recognize it and differentiate it from other elements and to which our knowledge of it is necessarily limited. There is a more or less defi-

nite gradation in these properties from element to element, showing an inter-relationship, and yet scarcely in itself justifying the conclusion that any one property determines the other or that they are dependent upon it. While it is true that it is hardly possible to dissociate these properties from some conception of matter, such conception has not yet reached its ultimate analysis and until it has we are dealing with the recognized properties alone.

In the same year in which the periodic system was forced to adjust itself to a zero group another discovery was entering upon its marvellous development which was to open up new views as to the nature of matter and radically affect the system. The remarkable and illuminating results obtained in the study of radioactive substances are paving the way for an understanding of the laws on which this system is based.

Radioactivity was regarded by Mme. Curie as an atomic property and this was the guiding thread which led to the discovery of radium. Of course, this preceded by a number of years Rutherford's announcement of his theory of successive transformation or the disintegration of the atom. It is a question whether the fact that an atom is undergoing disintegration is to be regarded as a property in the same sense as the mass, valence, etc., but so long as this change can not be induced, changed or stopped and is known to take place only in the case of a fraction of the elements it is certainly distinctive and may be called a property for lack of a better name. There is, however, undoubtedly a cause for this disintegration and this instability may be due to some inherent property of the atom.

At present there are some thirty-seven radioactive bodies known, with the possibility of still others being identified. Each has distinctive radioactive properties.

For a number of these the chemical and physical properties are known. Each is an atom hitherto unknown and must be considered a new element. Of course, the present accepted arrangement of the periodic system does not provide for so many additional elements and indeed is rather hopeless for even the sixteen rare earth elements. What is to be done with this embarrassment of riches?

Soddy's study of the grouping in well-known families of a number of the better known radioactive elements according to their chemical properties, combined with a consideration of the kind of disintegration by which it was produced led him to a generalization which would enable one to place correctly any radioactive element whose source was known, and at the same time give an approximation as to its atomic weight.

Fajans arrived at the same generalization independently from an examination of the electro-chemical evidence, finding that the product of an α ray change was more electro-positive, while that of a β ray change was more electro-negative. Similar conclusions from various evidence were reached by Fleck and Russell.

The generalization is as follows:

When an α particle is expelled it carries with it two atomic charges of positive electricity and the expulsion of these two positive charges from the atom affects the valency of the product, as Fajans has pointed out, just as in ordinary electro-chemical changes of valency. If the atom were initially in Group IV., for example, its ion is tetravalent and carries four atomic charges of positive electricity. Two such charges having been expelled with the α particle, the product is in the di-valent Group II., non-separable from radium. The mass in this case is four units less. So with the β ray change. The β particle is a negative electron and the loss of this single atomic charge of negative electricity increases the positive valency of the product by one. Radium B, for example (in Group IV.), expels a β particle and becomes radium C (in Group V.). When-

ever two or more radio-elements fall in the same place in the Periodic Table, then, independently of all considerations as to the atomic mass the nature of the parent element, and the sequence of changes in which they result, the elements in question are chemically non-separable and identical. As will later appear, this identity extends also to most of the physical properties such as volatility and spectrum reactions.²

To express this "newly revealed complexity of matter," Soddy has suggested the word isotope. A group of two or more elements occupying the same place in the periodic table, differing in atomic weight yet chemically non-separable, is isotopic. There are possibly seven such elements isotopic with lead. Radium is one of four isotopes. The chemistry of thirty-seven radio-elements is thus reduced to a smaller number of about ten types.

Two fundamental changes in the old views as to the system are indicated here. First, the position of an element is not fixed but can be changed in either of two ways—by a change in valence (which, as is well known, can be brought about in various ways), and again by disintegration due to ray-emission. Secondly, more than one element can occupy a given position in the system. This is independent of the atomic weight, but such elements are chemically inseparable. This involves the giving up of all idea of the properties being functions of the atomic weights and necessitates the formulation of the law anew.

The place occupied by an atom is not solely determined by its mass but by its electrical content as well. According to Soddy, the system represents the chemical character of matter as the function of two variables instead of one. The electrical content is the essential variable in horizontal columns and mass is the essential in vertical columns.

It is somewhat early to raise the question

² Soddy, "The Radio-elements and the Periodic Law," p. 6.

as to whether all elemental atoms are the result of disintegration processes, or, conversely, of synthesis, but in any case the old puzzle remains as to their great irregularity in weight relations if the most accurate chemical determinations are to be relied upon. If the time should arrive when they could be calculated, chemists would naturally return to hydrogen as the standard. Certainly, at present these weights present no simple synthetic relations.

An explanation of this is perhaps at hand if the view of Soddy (and of Crookes at an earlier period and from a different standpoint) is accepted, namely, that in atomic weight determinations it is not a natural constant that is obtained but a mean value of non-homogeneous masses. In other words, the weight may represent the average of various isotopic atoms and not the absolute weight of identical atoms.

It is very fortunate that the simple expedient of arranging the elements in the order of their atomic weights could give the early workers so nearly correct a view of the periodic system. It would probably have remained hidden for a long time if this had not been so prominent a factor in determining the proper sequence. There is undoubtedly a proper sequence. This has been settled hitherto chiefly by consideration of the atomic weight, but also by examination into the relationship existing between the elements. For instance, the order of atomic weights would be iodine and then tellurium, but chemically tellurium belongs to Group VI. and iodine to Group VII. Therefore, the atomic weight order is reversed.

The sequence numbers of the elements, or atomic numbers as they are called, assume a new practical and theoretical importance. Within twenty years after the announcement of the periodic system, some,

as Fedaroff, had sought to attach importance to these numbers, but the efforts had little to commend them. Lately it has been suggested by van den Broek that this is a fundamental and important number. Beginning with 1 for K, the numbers would be 2 for He, 3 for Li, 4 for Be, etc. The question then naturally arises, can these numbers be reliably determined without reference to the atomic weights and correcting the manifest mistakes made in following the simple order of these weights?

One method for doing so, though with limitations, lies in the measuring of the scattering of the α particles when passing through different kinds of matter. Geiger found that the angle of the scattering seemed to depend very largely upon the atomic weight of the scattering metal. A very small fraction are scattered through such a large angle that they return on the side of incidence. This deflection is, of course, both a volume and surface effect. For equal thickness of screen calculations based on Rutherford's conception of the atom and his belief that this large angle scattering is due to the near approach of the positively charged α particle to the positive nucleus of the atom of the screen would make the scattering vary as the product of the density by the atomic weight. Thus Rutherford calculated that the scattering by gold should be about fifty times that by aluminium. This has been confirmed by the experiments of Geiger and Marsden, and the relative scattering has been determined for a large number of elements. The phenomenon is manifestly one determined by the electrical content of the atom.

The nuclear charge of the Rutherford atom can be calculated from the α particle scattering at various angles. This charge is found to be one half the atomic weight multiplied by the charge of an electron.

The same value was reached by Barkla by observations on X-rays. Soddy concludes that it is the nuclear charge rather than the atomic mass which fixes the position of the element, basing his conclusion largely upon the work of Barkla, Sadler and Moseley, which will be briefly outlined further on. This in reality agrees with the hypothesis of van den Broek that the number of electrons in an atom in the neutral state determines the place of the element if hydrogen has one electron and one nuclear unit charge, helium two electrons and two nuclear unit charges, etc.

The direct method then is a combination of the work of Bragg, Barkla and Sadler, and Moseley. Making use of the work of those first mentioned, Moseley photographed the spectra obtained by the cathode-ray bombardment of a number of elements, the X-rays thus produced being reflected and defined from a crystal face. The frequencies of the vibrations could be determined and this frequency was found proportional to the square of the atomic number. That is, there was a definite shifting in the direction of shorter wavelength in the spectrum of an element from that of the one next above it in the list.

The graphic representation of the system has never been satisfactory in spite of the many efforts to solve it. It is especially difficult to bring out the facts by any representation on a plane surface. The faults of the Mendeleeff table can readily be seen, and they make it very desirable to secure a better mode of expression. And yet it is difficult to use the three dimensions of space so that the average student can grasp the whole. Soddy's lemniscate curve certainly has its good points. This may be compared with the arrangement of Rydberg. It can not be claimed yet, however, that the law or laws underlying this system are known and well understood, and until such time a com-

plete and satisfactory graphic representation is scarcely to be expected. We can agree at least that progress is being made toward such an understanding.

FRANCIS P. VENABLE

*SOME FALLACIES IN THE ARGUMENTS
AGAINST FULL-TIME CLINICAL
INSTRUCTION¹*

IN a recent paper, published in *SCIENCE*, Dr. S. J. Meltzer comments upon two notable facts in connection with the present rather active agitation regarding full-time clinical instructors. The two facts singled out by him are: (1) The appointment of full-time professor of medicine, surgery and pediatrics, by the Johns Hopkins University, and (2) the disparagement of this type of plan by the council on medical education of the American Medical Association. Dr. Meltzer's paper itself constitutes a third notable fact, in that it represents one of the very few unqualifiedly strong appeals that have been made by a clinician in favor of full-time clinical instruction. Although engaged at present in a so-called fundamental research, the current of Dr. Meltzer's life has been clinical to so large a degree, that his conclusions can not be questioned on the ground of academic impracticability. He analyzes the report of the council with logical seriousness; and were it not for the artifice of a single italicized word, one would scarcely feel the flick of Meltzer's lash or realize the seriousness of the attempt of the council to laugh the case out of court. Dr. Meltzer, by rare grace and tact, forges an argument so uncommonly well tempered as to render supportive discussion almost unnecessary. And yet, if there be any force in the plea for full-time heads of clinical departments, it lies in the line of duty of those of us who are clinicians to develop its full strength by discussion.

In such a discussion, as indeed in all such discussions, nothing contributes so much to balance and rationality as does a proper con-

¹ Read before the twenty-fifth annual meeting of the Association of the American Medical Colleges, Chicago, February 17, 1915.

ception of the historical perspective of the problem involved. It is essential to realize at the outset that the question is not a new one involving American medicine alone. Many men would have us believe that suddenly, as a result of this, that, or the other tendency, our clinical instruction in America has been found wanting, and that with typical American impulse we have set to moving in the sacred realm of education, the machinery of experiment. As early as the seventeenth century, Leibnitz attempted to justify his faith in quacks, on the basis that doctors were improperly trained as men of science, and that it was hopeless to look for the development of scientific teachings and methods in a practitioner, *der nichts thut als von einem Patienten zum andern rennen, und wenn er bey dem einen ist, auff den andern schon denket* (who does nothing but run from one patient to another and who, when he is visiting one patient, is already thinking about the next one). Almost a half century ago Billroth anticipated the Flexner report on Medical Education, in his "Ueber Lehren und Lernen," a work necessarily less modern in tone than Flexner's, less broad in the geographical consideration of the subject, but not a whit less emphatic in the assertion of corrective principles. Coming down to more modern times, we have the Report of the Royal Commission on University Education in London (1913) in which it is admitted that "the academic training received by medical students in London has not always been distinguished, and that the scientific spirit has been too often wanting." We in America have also found that, even in our best schools of instruction, the scientific spirit has been too often wanting, and we have found it wanting chiefly in the clinical branches. On this basis rests the agitation for full-time clinical instruction.

The phrase "full-time clinical instruction" signifies that the teaching of each major clinical subject be under the supervision of a properly qualified instructor, who shall serve as the head of his department, who shall devote all his energies during the working

school-day to the management of his department, who shall receive an adequate compensation for his highly specialized labor, and who shall be protected against the inevitable lures and enticements incident to his position, by a provision which denies him the right to accept private fees, or permits him to accept them only on such conditions as may be imposed by the university. This is the simple statement of the case. And as the question stands at present, its importance resides not in the working out of a detailed scheme of clinical instruction under such a plan;² but rather in formulating a critical judgment regarding the advisability and practicability of so modifying our method of clinical instruction as to make it conform to other approved methods of education.

And when we have said this we have hinted at one of the most paradoxically inexplicable phases of medical education. It may be stated that, almost without exception, *clinical* teachers realize the essential necessity for full-time men in all of the *fundamental* branches of medicine. The very canons of education demand such a system. Yet, a large number of these same clinical teachers assume that there is such a wide divergence between the teaching of the fundamentals and of clinical medicine, as to render wholly unwarrantable the conclusion that clinical teaching also should be based on that plan which alone is best suited for instruction in fundamentals. It is, for very self-evident reasons, natural that the scheme for full-time clinical instruction should have the strong support of most of the teachers of the fundamental branches. It is not so easy to explain the fact that opposition to the plan has come so largely from clinicians. Such a clean-cut division into camps is unfortunate, because it has set in motion a controversy tinged with bitterness. The so-called laboratory men are charged with a tenacious hold on impractical ideals, limited by virtue of a narrow occupational horizon; and the clinicians are, in their

turn, supposed to typify the old story, repeated in myriads of forms, of privilege clinging to tribute. Neither of these assumptions is entirely correct; both of them are essentially harmful because they drag the argument down to the low level of personalities. Disagreements of this sort usually rest on fallacious judgments. An unqualified advocate of the full-time clinical instructor, I have, for the past few years, noted various fallacies, patent or concealed, in the arguments against this plan of instruction; and the only object of this contribution is to examine these various fallacies, with the hope of clarifying a fairly well-confused topic.

Of all others, the fallacy most responsible for both bitterness and confusion is the assumption that full-time clinical instruction connotes a clean sweep, displacing all teachers who are private practitioners and replacing them by non-practitioners. Such a plan has the advocacy of no one. Barker, in his address on "Tendencies in Medical Education," falls into this particular fallacy when he develops the thought that "the present incumbents of clinical chairs" by virtue of "the rightfulness of the kind of work done by them" hold their positions in "good faith." He pleads the cause of these "honest, hard-working men" in such fashion as to warrant the inference that they are all to be displaced, and that their displacement is a breach of moral contract on the part of the university. Dr. Barker certainly does not, nor should any one else, minimize the value of such services as are rendered at Johns Hopkins University, for example, by those clinical men who are not on a full-time basis, simply because at that university there are academic heads to medicine, surgery and pediatrics. It is supremely important to recognize the fact that the varying character of clinical material will always make it both advisable and necessary for the university to offer place and preference to the properly qualified clinical teacher, irrespective to his affiliation with private practice. The full-time clinical instructor, together with his staff, is a necessary adjunct in organizing, coordinating and correlating

²Details of organization are purposely omitted, such, for example, as the number of full-time salaried assistants necessary to the successful conduct of a department.

the practical as well as the investigative work of his department, just exactly as the dean of a school is an adjunct in developing school spirit and school policy. The advocates of the full-time instructor should never, not even implicitly, subordinate the teaching value of the properly qualified private practitioner.

Even broader in scope is the fallacy that there is an important and essential variance of principle in teaching the clinical phenomena of disease, and in teaching function and structure or aberrations of both, in the laboratory. It is difficult to analyze this fallacy and at the same time avoid an undesirable discussion of the primary pedagogic principles involved in teaching medical students. It may be pardonable, however, to dip into abstractions just deeply enough to say that whether our efforts at teaching be confined to the fundamental or to the clinical branches, our aim is toward equipping our pupils to form proper judgments. If, as a result of their training, our students can affirm or deny conclusions, either by proper process of reasoning or by the direct comparison of objects to ideas, we may rest easy in the thought that the discipline of their medical education has been fruitful. And the process by which they should be taught to form proper judgments is exactly the same in the hospital ward as it is in the laboratory. In both places the student is taught to know certain fundamental truths, and from these he is taught to reason certain definite conclusions. The fact that in so many hospital wards and clinic rooms the student is taught *to know*, to the exclusion of being taught *to think*, is responsible, in large measure, for the fallacy that clinical teaching is, part and parcel, separate and distinct from fundamental teaching. If one doubts that clinical teachers err with hopeless frequency in this direction, let him pick up at random a number of clinical text-books and examine them critically. The conclusion will be unavoidable that preponderant stress and effort is laid on crowding the student with facts—on teaching him to know. One of the most recent clinical text-books states in its preface that the very best a

teacher can hope to do is to teach his student to know.

This particular fallacy regarding the specific difference between fundamental and clinical teaching should not be dismissed by merely stating it. It is essential to expose the danger to which it leads. And this can be done no better than by quoting a sentence from last year's report of the Conference on Medical Education. This report states that

Clinical teachers know that in the very nature of things the teaching of anatomy and pathology is in no way parallel to the teaching of medicine and surgery, because the teaching of medicine and surgery is inseparably associated with the practice of medicine and surgery.

This allows us absolutely no other alternative than the conclusion that anatomy and pathology are *not* inseparably associated with the practice of medicine and surgery. Surely the council can not hope that this conclusion will go unchallenged.

On the part of the clinicians there has always been a tendency to introduce this notion of the subtle, specific teaching value of private practice as a sort of abracadabra, charm, amulet, something to conjure with in the realm of medical education. They have studiously avoided the fact that the plan for full-time clinical instruction contemplates developing the principles of practice in their most utilizable form, namely from a variety of clinical material, intensively correlated and studied, and housed under one roof. Is there more to be learned of the basic traits of human nature on Fifth Avenue, or on Michigan Avenue, than there is in the wards of Bellevue or of Cook County Hospital? Or does the wealthy patient have a more legitimate demand on a larger share of the sympathy, interest, pity, or sweetness and light of his doctor's pervasive personality than does the helpless sufferer in the charity ward? The plan for full-time clinical instruction *does* contemplate the full realization of the intimate relationship between teaching medicine and practicing medicine; what it does *not* contemplate is the injudicious mixture of private practice and teaching. And in this particular, the plan is strong against all

attack or argument, for the very reason that the majority of clinicians do not (and very properly do not) use their private patients as teaching material and could not even if they were so minded.

And all this leads up to another false assumption. It is argued that since from the standpoint of medical education, so little store is laid by a man's capacity to gain and hold the medical confidence of a large clientele, and to serve it intelligently and well, it necessarily follows that the rôle played by the private practitioner is less ennobling than that of his fellow who elects to be exclusively a clinical teacher. The practising physician very naturally resents such an inference. In reality, any conclusion which sets a comparatively lower value on the services of the private practitioner than on those of the exclusive clinical teacher, by reason of the fact that material remuneration is greater in one field than in the other, is a *non sequitur*. Certainly all thinking men realize that between the *spirit* of practise and the *spirit* of teaching there is no essential ethical difference. The value of effort in either field is directly proportional only to the grade of intelligence and purpose back of it. But between the *demands* of practise and the *demands* of teaching there is a variation so pronounced, qualitatively and quantitatively, as practically to preclude the proper performance of both these functions by the same individual. The full-time plan, therefore, rests upon this very rational conception of the case, and implies absolutely no measure of comparative worth between the vocations of practitioner and teacher.

In the teaching of such eminently practical branches as law, engineering, commercial chemistry, and other technical specialties, the need of the full-time instructor has been recognized and met. There seems to be nothing specifically so different in the practise of medicine as to demand that it be regarded as an exception in the general field of education. On the contrary, the teaching of clinical medicine demands the services of unattached men more urgently than does the teaching of any other practical art or science, because the two purely physical elements of time and fatigue enter so

intimately into the problem. Barker has emphasized the overwhelming amount of correlated knowledge to be appropriated by the clinical teacher of to-day; an amount of data almost sufficient "to suffocate" him. This process of appropriation requires, in addition to intelligence, a very definite number of hours and minutes each day. An active practise rarely grants the necessary surplus of time. If, however, by a process of "speeding up," the practitioner succeeds in cleaning his slate, in order to fulfil his teaching obligations, he is very apt to find himself face to face with that other disturbing physical element—fatigue. It has always seemed a remarkable fact that the study of fatigue in its relation to efficiency should have been confined to the industries. We accept as true the fact that more than a given number of hours in his cab renders the locomotive engineer an unsafe person to differentiate between the two primary colors red and green; but we have to prove by argument that the busy surgeon can shoulder the enervating duties that confront him day and night, and still be fit for one of the keenest of all mental disciplines—the proper teaching of science.

And let us pause here just long enough to emphasize this word science in its relationship to clinical medicine. Not the least significant of the various fallacies that we are examining is the one that has to do with the thought that the fundamental man *must* be a specialist, and *must* be on a full-time basis because, although of course he is a teacher, he is also an investigator and must therefore have the necessary time for *scientific* research. By inference again we are subtly led to believe that scientific research is confined to anatomy or physiology or one of the other cognate fundamental branches of medicine, and that it need not be reckoned with in considering the teaching of the clinical branches. Those who favor the plan of full time clinical instruction are influenced in no small part by the hope that the properly qualified clinical teacher, favorably situated, will foster, stimulate and direct scientific clinical research of a higher order than is commonly produced under our present system of conducting clinical teaching. Clin-

ical investigation is, of all other types, probably the most intricate and difficult, for the reason that the problems studied are of such a nature that the factors entering into them can not, as a rule, be varied at the will of the investigator. If, therefore, we hope to encourage worthy product along the lines of scientific clinical research, we must, to say the least, provide the clinical teacher with an environment as favorable as the one with which we surround the fundamental teacher. It is no answer to this argument to quote the numerous examples of epochal discoveries made by busy practitioners. The superman will inevitably enrich his field, in the face of compromising odds or even of grueling adverse conditions. The problems of education always deal with averages, and what we desire to see is a system attuned to producing from among the common ranks of medical men a proportionately large number of clinical teachers and investigators.

We base our hopes on the full-time plan as an aid in attaining this worthy end, and all seems well until we are rudely halted by the oft-cited example of Germany, the nourishing mother of all that is best, and stable, and approved, in medical education. Germany has no full-time clinical instructors, and, what is more, the very men whom we all recognize as her leading clinical educators have not a particle of sympathy with the American full-time plan. Here truly is a stumbling block. And yet, the explanation is not as difficult as it appears to be. German clinical teachers, in spite of their unqualified rights to practise, have mortised themselves into medical history, so that their names fairly dot pages. More than that, practically every great German clinical teacher has developed about him a so-called school of younger men. By contrast, we have at home a proportionately very small number of names that even the most chauvinistic among us would set up with the leaders of German clinical thought, and only comparatively few of our clinical teachers have grouped a school of enthusiasts around them. But this contrast does not signify that the German clinical professor is efficient because of his uncompromised right to practise. At all events, it would be difficult to establish

proof to this effect. It seems much more likely that he is efficient in spite of the fact that he shoulders the distractions of practise. Indeed, those who have come into intimate contact with the directing heads of clinical departments in Germany know that many of them resolutely set themselves against these distractions. Friedrich Mueller, of Munich, may be selected as a type. Mueller considers his two-hour *sprechstunde* devoted to private patients, as a type of relaxation, comparable to golf, mountain climbing, or other forms of diversion. No inducement will persuade him to lengthen the office hour, and he refuses to make extra-urban visits, under ordinary circumstances, unless there be some teaching value inherent in the call. His serious work is teaching and directing, to both of which he devotes consummate care, and consequently a large amount of time. Between Mueller as a teacher of medicine and, let us say, Marchand as a teacher of pathology, there is no essential difference. They are both so-called fundamental men, each in his own specialty; and Mueller represents the type that the advocates of full-time instruction in America hope to develop—the fundamental clinician as teacher.

If we be asked why we concede that private practise has not militated against the development of the highest type of clinical teacher in Germany and has so markedly militated against it in America as to call forth an edict of interdiction, we can answer only that the variance between German and American culture and traditions so profoundly influence thought and act as to render it impossible to graft, unaltered, a system of thought from one country to the other. It is likewise equally impossible to argue that because certain conditions are favorable from an educational point of view in one country, they must of necessity be favorable in the other. The German is the type of patient plodding lover of *gemuetlichkeit*, who, certainly up to recent times, did not labor in medical fields under a very heavy stress of commercial competition. Tradition requires that he advance to scientific preferment only through a *dozentship*, and this in turn implies approved excellence as teacher or producer. The American, on

the other hand, is the mercurial, restive type, who hasn't even a word in his vocabulary with which to translate *gemuetlichkeit*, and who labors medically in a strenuously competitive atmosphere. The essence of the matter is simply this, that up to now the German clinical professor has, as a rule, needed little or no protection against himself, whereas the American clinical professor has so frequently demonstrated the need of such protection as to call forth that forcible truth from Dr. E. P. Lyon, who characterized clinical professorial selfishness by the phrase "lying full length in the trough as he eats." If a sufficiently large number of American private practitioners had demonstrated their capacity to combine teaching and practise as the Germans combine them, there would probably be no call for the full-time clinical professor. They have failed to demonstrate this, and they can not explain that failure on the basis of German example.

Indeed, this failure on the part of the clinical teachers to teach as intensively as do the instructors in the fundamental branches is alone responsible for the agitation for the full-time clinical instructor. Whether they accept it or not, the burden of proof lies upon those who argue against a plan that attempts to do for clinical teaching exactly what has been recognized as essential in practically every other branch of education. For many of us it is difficult to see how the introduction of full-time clinical instruction can possibly fail to accomplish most of those things which we hope to see result from it, for all of us who are interested in seeing the reform meet with warm, broad support, there is much chagrin and disappointment in contemplating the half-hearted support and whole-hearted opposition accorded it. This chagrin and disappointment may be considerably tempered, however, if we bear in mind the truism spoken by President Lowell in his address before the New England Association of Colleges, last year. Said Mr. Lowell:

Education is the last of all things to follow the stream of human thought and progress. It is still mainly in the deductive stage.

If Mr. Lowell be correct in his statement, we may seek solace in the thought that we have

at least an explanation for the fact that so many well-meaning clinical men experience difficulty in accepting an inductive syllogism the conclusion of which is "The teaching of clinical subjects should be under the guidance of exclusive clinical teachers."

MAJOR G. SEELIG

ST. LOUIS UNIVERSITY SCHOOL OF MEDICINE

CHARLES E. BESSEY

THE death of Professor Bessey removes a conspicuous figure from among the group of older American botanists. No botanist was better known personally among his colleagues, for he was eminently social, and enjoyed the various scientific meetings that brought his friends together. It is certain that no member of the botanical fraternity will be more missed at these meetings than Professor Bessey, for he was always the center and life of any group of which he happened to be a member.

The usual biographical data dealing with birth, training and official positions may be obtained from "American Men of Science," and need not be repeated here. The writer wishes to speak of him as an old acquaintance, and of his place in the history of American botany.

Professor Bessey first became known to botanists in general in connection with his position in the Iowa Agricultural College at Ames, and during his fourteen years (1870-84) of service there, his reputation as a botanist became established. In 1884 he began his long period of service at the University of Nebraska, where for thirty-one years (1884-1915) he was not only a commanding figure in his subject, but also in the university and in the state.

In the history of American botany, Professor Bessey stands for the introduction of a new epoch. Before 1880 the study of botany was practically bounded by the taxonomy of the higher plants, with such gross morphology as enabled the student to use a manual. In any event, the collecting and naming of plants was the chief botanical pursuit. For nearly thirty years before 1880, morphology as we understand it now had been developing in Germany, under the original stimulus given

by Hofmeister. The belated introduction of American students to this new field of botany was brought about by Professor Bessey, when in 1881 his "Botany" appeared. This volume not only brought the atmosphere of Sach's *Lehrbuch* to American colleges, but also compelled the development of botanical laboratories. For the first time, all plant groups became available, and cells and tissues became materials for study. The original "Botany" was the first of a long series of texts, and for many years "Bessey's text-books" set the standard for modern work. If Professor Bessey had made no other contribution to American botany than the publication of this book at the psychological moment, he would have made for himself an enduring place in the history of American botany.

The qualities that led him to discover and introduce to American colleges the new botany, also suggest that he was a great teacher. Perhaps no American botanist has left his mark on so many students as did Professor Bessey. He was certainly "apt to teach," and this was shown not merely by his neverfailing enthusiasm for his subject, but also by his stimulating companionship with his students. He lived in his subject and lived with his students, and his "dingy and cramped quarters," as they were called, seemed to cultivate the spirit of camaraderie in the whole department. The students of Professor Bessey are scattered everywhere in responsible positions, and the writer has never met one of them who has failed to pay the warmest tribute of loyal affection to the man who taught him.

Professor Bessey was not merely a great teacher, both through his text-books and in contact with his students, but he was also a public-spirited citizen. He felt that the whole state of Nebraska was entitled to his services, and he gave of his time freely to organizations of all kinds that were seeking to develop the various interests of the state. The plant life of the state, the agricultural possibilities of the state, the teaching of agriculture in the schools, all engaged his attention.

Recognition of Professor Bessey by his colleagues throughout the country came as a matter of course. He was not only a member

of the various national organizations, but he was elected to almost every office to which an American botanist can aspire, culminating in the presidency of the American Association for the Advancement of Science. One of the characteristics of Professor Bessey most frequently remarked among his colleagues was his refusal to speak unkindly of any one. No one ever heard from him the sharp and occasionally envious criticism that too often mars the fine qualities of scientific men. Even in his work as a reviewer, where criticism is invited, he always searched for the pleasant things to say, and left the unpleasant things unsaid. Those of us who knew him best realize that he did not even think of the unpleasant things, but that his kindly nature was always seeing the good in every botanist.

Professor Bessey was a voluminous writer, as a man full of ideas, energy and of the teaching spirit is apt to be, so that it would be impossible to cite his bibliography here; it will doubtless appear in fitting form in some more appropriate connection. The present purpose is simply to express an appreciation of a great teacher of botany by a colleague who has known him intimately throughout almost his entire public career.

JOHN M. COULTER

FRANK OLIN MARVIN

PROFESSOR FRANK OLIN MARVIN, dean of the school of engineering of the University of Kansas, died in San Diego, Calif., on February 6, 1915. Dean Marvin was born in Alfred Center, N. Y., in 1852. He was the son of Dr. James Marvin, for many years professor of mathematics in Alleghany College, and later chancellor of the University of Kansas.

Graduating in 1871 at Alleghany College, Professor Marvin devoted several years to practical engineering work, and was in 1875 appointed instructor in mathematics and physics at the University of Kansas. In 1888 he was appointed professor of civil engineering, and when, in 1891, the university was reorganized and a school of engineering was established he was elected to the position of dean. He was untiring in his labors for the upbuilding of this most important school, from this

time until 1912, when impaired health compelled him to retire from active work, although he was retained on the faculty as advisory dean. Last year he was granted a retiring allowance by the Carnegie Foundation.

It may be truthfully said that Dean Marvin devoted his life to the cause of engineering education. He worked and wrote for its advancement. In 1901 he was elected president of the Society for the Promotion of Engineering Education. He was one of the charter members, and the first president of the Kansas chapter of the Society of the Sigma Xi, one of the earliest chapters of this organization established. He was honored with the presidency of the national organization, and did much to shape the policy and raise the standard of this society.

As an active member of the American Association for the Advancement of Science (vice-president in 1896); of the American Society of Civil Engineers; of the Society on Testing Materials; Kansas Academy of Science; and as advisory member of the Kansas State Board of Health, he took an active part in the work for the encouragement of research and the advancement of scientific knowledge.

His colleagues in the university and the thousands of students who have been under his instruction, feel that a friend has gone. In the words of one of Dean Marvin's former students:

He was further qualified for his work by his culture and refinement. No man was better fitted than Frank Marvin to plant in his boys the desire for the fine things of life. He was a reader, a student, an artist. Through all the busy years of striving and building, of creating great properties, or of humble service in some of the quieter places in life, Frank Marvin's boys look back to the school days of long ago and recall the quiet cultured gentleman who gave them so many ideals and who in his own life so lived these ideals.

The University of Kansas has honored the name of the first dean of its engineering school by naming the new engineering building "Marvin Hall," and the former students and friends are about to place in the building a bronze bust to commemorate his name.

LAWRENCE, KANS.

E. H. S. BAILY

THE CHEMICAL INDUSTRY IN GREAT BRITAIN

The position and prospects of the British dye industry were discussed by Dr. W. H. Perkin, Waynflete professor of chemistry, Oxford, in his presidential address delivered on March 25 at the annual general meeting of the Chemical Society, London. Dr. Perkin is the son of the late Sir William Perkin, F.R.S., the discoverer of aniline dyes. "The Position of the Organic Chemical Industry" was the title of the lecture, and Dr. Perkin according to an abstract in the *London Times* at the outset expressed his conviction that the causes of the decadence of the industry in this country were still imperfectly understood. One of the main reasons for our present position was that we, as a nation, and our manufacturers in particular, had failed to understand the extreme complexity of the scientific basis of organic chemical industry. The decadence of the coal-tar industry and its gradual transference to Germany began during the period from 1870 to 1875. It was in 1874 that the works of Perkin and Sons at Greenford Green were sold to the firm of Brooke, Simpson and Spiller, and these works were then much in advance of anything that existed in Germany. One reason for the sale, Dr. Perkin said, was his father's natural dislike to an industrial career, and his desire to devote himself entirely to pure chemistry.

There was, however, a much more weighty consideration. It was recognized that the works could not be carried on successfully in competition with the rising industry in Germany unless a number of first-rate chemists could be obtained and employed in developing the existing processes, and more particularly in the all-important work of making new discoveries. Inquiries were made at many of the British universities in the hope of discovering young men trained in the methods of organic chemistry, but in vain.

The value of the coloring matter consumed in the United Kingdom was £2,000,000 per annum, and these dyes were essential to textile industries representing at least £200,000,000 a year and employing $1\frac{1}{2}$ millions of workers, and

to many other industries such as the wall-paper, printing and paint industries requiring lakes and pigments.

In 1870, the time when this industry commenced to be transferred to Germany, organic chemistry was not recognized by our older universities, and the newer universities, which since then had done so much for the progress of science, did not exist. Many of our universities and particularly those of Oxford and Cambridge, and those in Scotland, contributed practically nothing to the advancement of organic chemistry in the latter part of last century, and even now their output of research was far less than it should be. In Germany, as soon as the importance of the subject became apparent, schools specially devoted to the subject were founded by such teachers as Liebig, Wöhler, Kekulé and Baeyer.

The president then dealt with the deficiency of dyes in this country, and referred to the schemes proposed by the government to ascertain the best means of obtaining sufficient supplies of chemical products. The grant of £100,000 which the government proposed to make to the company for research purposes would be better employed in subsidizing the research laboratories of those universities and colleges which were willing to specialize in organic chemistry, and to train a certain number of students with a view to their entering the services of the company. The existing dye works in this country compared very unfavorably, he said, with those in Germany, where experience had been in favor of building large works and against spreading manufacturing operations over small works situated in different parts of the country. Moreover, in the manufacture of any substance, by-products resulted which must be either recovered or used in the manufacture of other saleable products, and in order that these by-products might be used to the best advantage the dovetailing operations should be carried out on the same site, and thus save transporting the by-products from one works to another—an operation that must entail loss. The proposal of the government, therefore, to take over the existing works in this country appeared a doubtful policy.

INTERSTATE CONFERENCE ON CEREAL INVESTIGATIONS

THE undersigned committee on arrangements respectfully announce that on May 25-28, 1915, an Interstate Conference on Investigations of Cereals will be held in California. This proposed conference is the outgrowth of suggestion and expressed desires on the part of many investigators for a number of years that such a conference be held for the purpose of conferring on the various phases of all cereal research but particularly those more difficult problems concerning which there is difference of opinion, different methods of work, different points of attack and considerable variation in results, in order that these differences may be better understood by each other and that all such investigations be more coordinate and effective hereafter.

It seems that the fact that there are no other meetings at that time to conflict with this one and the fact that it is near harvest time in that region would be much in favor of having the conference at the time stated. It is realized that the time may be inopportune for some and that many in the eastern part of the United States will not be able to attend. It is hoped, however, that even of those in the east there may be certain ones who would in any case visit California about that time and who would avail themselves of the opportunity to take part in the conference. It is hoped and expected that there will be a good attendance from the territory west of the Mississippi River. A number have already signified their intention of being present and several have submitted titles of papers.

The arrangements are: To meet at Merced Tuesday, May 25, for a field inspection of the San Joaquin Valley cereals, go to Berkeley the evening of the same day and begin the conference proper the morning of the 26th at the University of California; continue the program the next day at the State Experiment Farm at Davis and finish the day with an inspection of the farm; then go to Chico in the evening or the next morning and visit the Plant Introduction Garden of the United States Department of Agriculture on the 28th. During the same day those who wish will go

by automobile to Biggs to inspect the Rice Experiment Farm at that place. That day will end the conference, after which the individual delegates will spend such other time and go to such other points within the state as they desire.

The following are proposed as general subjects for discussion, under each of which such subtopics may be discussed by different members as their inclination may dictate:

1. Problems of Pacific coast wheat production.
2. Improvement of barley for the Pacific coast.
3. Problems in cereal smuts.
4. Grading, milling, malting and baking.
5. Weed control in cereal production.
6. Tillage and crop rotation.
7. Insect enemies of cereals.

A program in detail will be issued later. It is expected that the discussions will cover a broad field. Millers, malsters and other dealers in grain, as well as agronomists, pathologists, chemists and entomologists are expected to attend. Among the foreign investigators expected to be present is Dr. F. Kølpin Ravn, professor of plant pathology at the Royal Landbohøjskolen, Copenhagen, Denmark. It is requested that each one expecting to attend make the fact known at once to some member of the committee. Titles of papers should be sent to M. A. Carleton, Department of Agriculture, Washington, D. C., and any other communications of inquiry concerning arrangements for meetings and other local information to Dr. J. W. Gilmore, University of California, Berkeley, Cal.

THE HARPSWELL LABORATORY

THE Harpswell Laboratory, which has been maintained for several years at South Harpswell, Maine, as an institution of research, has

been incorporated under the laws of Maine and has been placed in charge of a board of ten trustees. According to its charter, it is to be devoted to scientific study and investigation, while its constitution provides that institutions contributing funds to a specified amount will be entitled to appoint a trustee to represent its interests in the laboratory, the remaining trustees being elected annually by the corporation. The membership of the corporation includes those who have conducted investigations there and who have paid annual dues of one dollar for the current year.

Since its establishment, the laboratory has afforded facilities to 79 different individuals who have carried on investigations there. These have represented 43 institutions of learning. There have been published as based wholly or in part on investigations in this laboratory about sixty papers, making a total of about two thousand pages, illustrated by many figures and plates.

During the last season fourteen persons carried on research at the laboratory, these coming from Tufts College, Wellesley College, Wistar Institute, Johns Hopkins University, Northwestern University, Washington University and the University of Illinois. Their investigations covered: The exact homologies of the somites in the lower vertebrates, origin of taste-buds in Elasmobranchs, the nerves of the electric organs in skates, the morphology of the lungs and airsacs in birds, structure and functions of the ampullae of Lorenzini, the development of the Piperaceae, structure and development of the epiphysial organs of the dogfish, early development of *Clava*, development of liver and pancreas of *Acanthias*, the morphology of the hypophysis of Elasmobranchs and the skull of the dogfish.

The most important addition to the equipment for the year was a motor boat, 26 feet long with a two-cylinder, ten horse-power engine which puts all parts of Casco Bay within easy reach. The boat which had served for ten years was too small and had developed some of the infirmities of age. The library has been increased by several gifts and now contains over a thousand volumes and

pamphlets devoted to biology. It has several complete series of journals and some others of which only a few volumes are lacking.

The most imperative need of the laboratory is a new building capable of accommodating twenty investigators at one time, with a practically fireproof part for the library and valuable apparatus. Another necessity is a larger income. At present the laboratory is supported by subventions from several institutions. For several years the work has been carried on at an expenditure of less than \$500 in any one year. Out of this small sum a collector has been employed, the absolutely essential supplies have been bought and some additions have been made each year to the permanent equipment.

During the coming season the laboratory will be open from about June 20 to September 10. It offers especial facilities for the embryology of the fishes and for experimental work on that most favorable material, the eggs of *Cerebratulus* and of *Echinarachnius*. The more northern fauna marks the laboratory off from similar institutions farther south, while the location assures one of a cool summer. No instruction is given, but the facilities are offered free to those competent to carry on investigations. All communications as to places in the laboratory as well as to accommodations in the town should be addressed to either Professor H. V. Neal, Tufts College, Mass., or to J. S. Kingsley, Urbana, Illinois.

SCIENTIFIC NOTES AND NEWS

DR. J. GEORGE ADAMI, professor of pathology in McGill University, Montreal, has left for England to take up work as a member of the British War Office, having charge of the preparation of a medical history of the war.

DR. S. ALFRED MITCHELL, formerly assistant professor of astronomy at Columbia University, and now director of the Leander McCormick Observatory at the University of Virginia, has been appointed Ernest Kempton Adams Research Fellow by the trustees of Columbia University.

OWING to the illness of Dr. Theobald Smith, the dinner which was to be given in his honor

at the Harvard Club, Boston, on April 17, has been postponed until June.

THE Medical Club of Philadelphia announces a reception to be given at the Bellevue-Stratford, on April 23, in honor of Edgar Fahs Smith, LL.D., provost of the University of Pennsylvania; Alba B. Johnson, Esq., for the president of Jefferson Medical College; David Milne, Esq., president of the Medico-Chirurgical College of Philadelphia, and Russel H. Conwell, D. D., president of Temple University.

DR. EDMUND B. WILSON, Da Costa professor of zoology at Columbia University, has been appointed by the trustees to be speaker at the opening exercises of the university, on September 22.

THE van't Hoff fund committee of the Academy of Sciences of Amsterdam has awarded \$120 to Dr. E. D. Tsakalotos, of Athens, in aid of his researches on the thermal properties, the viscosity and the magnetic susceptibility of binary mixtures, capable of yielding endothermic compounds.

THE Academy of Sciences at Vienna has allowed \$200 to Professor H. Dexler, of Prague, to aid in continuing his studies on stimulation of the brain cortex in the horse, and \$150 to Dr. E. Pernkopf, of Vienna, to aid in his study of the development of the intestines and omentum.

DR. GEORGE SARTON, editor of *Isis*, who was compelled to leave Belgium with his family on account of the war, has accepted a lectureship at George Washington University. Dr. Sarton will lecture on the history of science. At the close of the war, it is his intention to return to Belgium and resume the publication of *Isis*.

THE Longstaff medal for 1915, of the Chemical Society, London, has been presented to Dr. M. O. Forster, F.R.S.

THE Samuel D. Gross prize of the Philadelphia Academy of Medicine for the year 1915 has been awarded to Dr. John Lawrence Yates, of Milwaukee, for his essay entitled, "Surgery in the Treatment of Hodgkin's Disease." The amount of this prize is \$1,500.

PROFESSOR W. WINTERITZ, of Vienna, known as the founder of scientific hydrotherapy, celebrated his eightieth birthday on March 1.

PROFESSOR LILLIAN J. MARTIN, of Stanford University, has undertaken the chairmanship of the committee of the American Psychological Association appointed to arrange for and conduct the program of psychology to be held at San Francisco during the first week of August. The committee otherwise remains as previously announced, the additional members being Professors G. M. Stratton and Warner Brown, of the University of California.

DR. W. H. MANWARDING, of Stanford University, has been appointed chairman of the pathological section of the National Association for the Study and Prevention of Tuberculosis, that will meet in Seattle, Wash., from June 14 to 16.

IN accordance with a provision in the annual Naval Appropriation bill, President Wilson has appointed an advisory committee on aeronautics. The purpose of the committee is to map out plans for stimulating aviation in the army and navy, and to adopt the best measures for overcoming the relative weakness of the United States military services in this field. The committee is composed of Brigadier-General George P. Scriven, chief signal officer, U. S. A.; Lieutenant-Colonel Samuel Reber, aviation section of the Army Signal Corps; Captain Mark L. Bristol, U. S. N., in charge of the Naval Aeronautic Service; Naval Constructor Holden C. Richardson, U. S. N.; Dr. Charles D. Walcott, secretary of the Smithsonian Institution; Charles F. Marvin, chief of the Weather Bureau; Dr. S. W. Stratton, chief of the Bureau of Standards; Byron R. Newton, assistant secretary of the Treasury; Professor W. F. Durand, of Stanford University; Professor Michael I. Pupin, of Columbia University; Professor John F. Hayford, of the College of Engineering, Northwestern University, and Professor Joseph S. Ames, of the Johns Hopkins University.

PROFESSOR G. D. HARRIS, of Cornell University, will repeat this summer the tour which he took last summer. The trip will be made

in the motor-boat *Ecphora* and will cover approximately the same territory as last year. The party will leave Ithaca early in June and will consist of Professor Harris and the six or seven graduate students who intend to make geology their life work. The route chosen takes an inland course down the Atlantic coast, planned in such a way that the geologists can study the different rock systems of the geologic column. From Cayuga Lake the party will enter the Erie Canal via the Montezuma Canal, proceed to Albany and thence down the Hudson to New York, cross New Jersey by the New Brunswick Canal and reach Chesapeake Bay through the Delaware River and the Delaware-Chesapeake Canal. The last part of the journey will be a tour through the canals of the Dismal Swamp, and the trip will end in the vicinity of Wilmington, North Carolina.

DR. ALLEN W. FREEMAN, Richmond, Va., has resigned as assistant state health commissioner to become epidemiologist for the U. S. Public Health Service at Washington.

STUART P. MILLER, graduate assistant in the chemical department of the Massachusetts Agricultural College, has accepted an appointment with Parke, Davis and Company, of Detroit, Michigan.

A GENERAL meeting of the New York Academy of Sciences and its affiliated societies is announced for Monday, April 26, 1915, at the American Museum of Natural History. There will be a social hour, with refreshments, beginning at 9:30 P.M., preceded, at 8:15 P.M., by a lecture under the auspices of the Section of Astronomy, Physics and Chemistry, entitled "The Volcano Kilauea in Action," illustrated with lantern slides, by Dr. Arthur L. Day, director, Geophysical Laboratory, Carnegie Institution, Washington, D. C.

DR. VICTOR C. VAUGHAN, professor of hygiene and preventive medicine in the University of Michigan, Ann Arbor, delivered an address at a special meeting of the College of Physicians of Philadelphia, on April 12, on phases of modern military hygiene and camp sanitation, particularly in reference to war mortality.

PROFESSOR DOUGLAS W. JOHNSON, of Columbia University, delivered an illustrated lecture on "Surface Features of Europe as a Factor in the War," at Johns Hopkins University on April 8. On the preceding evening he addressed the Harrisburg Natural History Society on "The Origin of Scenery in the Grand Canyon District."

ON April 16 Mr. R. J. Hammond, chemist of the U. S. Bureau of Mines, lectured at the University of Illinois on "The Radium Industry in America."

DR. A. J. CARLSON, of the University of Chicago, spoke before six hundred students in physiology at the Ohio State University on April 9. He chose as his topic "Some Recent Contributions to the Physiology of the Stomach." Dr. Carlson summarized his investigations, giving especial attention to the cause of hunger pangs. This was the final lecture in the annual series offered by the department of physiology to its students. Professor Carlson will address a joint meeting of the Alpha Omega Alpha Chapter, of the Western Reserve Medical School and the Section of Experimental Medicine of the Cleveland Academy of Medicine on May 14 at the Medical Library on "Some Recent Contributions to the Physiology of the Stomach."

A STATED meeting of the Geographic Society of Chicago was held on April 9, when a lecture was given by Mr. Charles W. Furlong, of Boston, Massachusetts, the title being "Chile and the Fuegian Archipelago."

PROFESSOR ARTHUR E. HAYNES, who for eighteen years held the chair of mathematics at the University of Minnesota until his retirement in 1911, died on March 12, at the age of sixty-six years.

DR. ERNEST P. MAGRUDER, of Washington, D. C., one of the physicians at the head of the American Red Cross unit in Serbia, has fallen a victim to typhus fever. For the last five years before going to Serbia Dr. Magruder had been professor of clinical surgery in Georgetown University.

THE death is announced from Berlin of Professor Friedrich Loeffler, the distinguished

pathologist, who in 1884 discovered the diphtheria bacillus. Dr. Loeffler was born on June 24, 1852.

DR. ARTHUR SHERIDEN LEA, formerly university lecturer at Cambridge, known for his researches in physiological chemistry, died on March 23, at the age of sixty-one years.

PROFESSOR GEORG JOCHMANN, of Berlin, has died from typhus fever, contracted in one of the camps for Russian prisoners.

DR. AUGUST VOLKENHAUER, docent for geology in Göttingen, has been killed in the war.

THE *Journal* of the American Medical Association records deaths among foreign students of the medical sciences as follows: A. Birnbacher, professor of ophthalmology at the University of Graz, aged 66, an authority on glaucoma in particular, but best known, perhaps, by his operation for ptosis and for cataract and his method of illumination of the eye; J. D. Pinero, professor of anatomy at the University of Buenos Aires and chief of the sanitary inspection service of the port and of the vaccine service, member of the national board of health and physician in chief at the hospital for men; J. G. Rueda, president of the board of health for the province of Cordoba, Argentina, governor, and member of the national senate, aged 53; G. Resinelli, professor of obstetrics at the University of Florence, aged 50; H. Apolant, a coworker with Ehrlich at Frankfurt, aged 48; Kreisarzt Filgensträger, of typhus contracted at the Langensalza camp of prisoners; Otto Markus, assistant at the Würzburg medical clinic, killed by a shell during the Argonne fighting. He leaves unfinished an important work on the histology of the ganglion cells of the nervous system.

THE next annual meeting of the American Psychological Association is set for December 28, 29, 30, at Chicago, Ill.

GOVERNOR WHITMAN has signed the Walters bill, which appropriates \$50,000 for the eradication of the foot and mouth disease.

GOVERNOR FIELDER has signed the bill giving to the State Board of Health the power to grant to regularly incorporated colleges,

universities and philanthropic institutions in New Jersey permission to make experiments on animals under certain restrictions. The Rockefeller Foundation for Medical Research will now begin work on the construction of a laboratory near Princeton for the study of animal diseases. The ground, buildings and equipment of the new laboratory will cost, it is estimated, \$1,000,000. As has already been announced, Dr. Theobald Smith, professor of comparative pathology at Harvard, will direct the institution.

We learn from the *Journal* of the American Medical Association that the Langenbeck-Virchow building, the new home for the medical and surgical societies of Berlin, is on the point of completion. The library is already being moved into the new quarters. By combining several scattered medical libraries, it starts with 113,000 volumes.

ACCORDING to a cablegram from Nish, dated April 11, the British and French governments are sending large numbers of military surgeons into Serbia to fight the epidemic of typhus. Thirty English surgeons have already arrived. Fifty French physicians arrived on April 10 and fifty more are expected shortly, as well as a party sent out by the Rockefeller Foundation and the American Red Cross.

The Journal of Criminal Law and Criminology is entering upon the publication of a series of monograph supplements which will be known as Criminal Science Monographs. The first monograph is now in the press. It will appear early next fall under the title "Pathological Swindling and Lying." Dr. William Healy, of Chicago, is the author. The volume will approximate two hundred pages. Each number in this series will be bound in cloth, and will come from the press of Little, Brown and Co., Boston, Massachusetts. Persons who have manuscripts in hand or in preparation, which they wish to have considered for publication in this series should communicate with Professor Robert H. Gault, Northwestern University, Evanston, Illinois.

The Prussian department of education has petitioned the legislature for a continuance of the appropriation of 25,000 marks, which for

six years has been granted for cancer research, on condition that private subscriptions would double the amount. This has always been done, and the private subscriptions are already assured for 1915. The appropriation is devoted mainly to the cancer research work being done under Professor Ehrlich's supervision.

An institution for ethnological research has been founded in Leipzig. The new institution forms part of the King Friedrich August Foundation for Scientific Research. It is affiliated with the Ethnographic Museum of Leipzig, and is furthermore in close connection with the Ethnological Seminar at the university. Dr. Karl Weule, director of the museum, is also director of the research institution. It may be expected that excellent results will be obtained by this concentration of effort, which contrasts favorably with the dispersion of energy as found in cities like Vienna and St. Petersburg and in most cities of the United States.

UNIVERSITY AND EDUCATIONAL NEWS

HARVARD UNIVERSITY receives \$100,000 by the will of James J. Myers, of Cambridge.

GIFTS amounting to \$72,908, to be devoted to cancer research at the Harvard Medical School, are announced. The sum of \$50,000 was provided by the will of Philip C. Lockwood.

By the will of Mrs. Laura L. Ogden Whaling, of Cincinnati, Miami University receives \$250,000 for a dormitory with \$10,000 for its support. \$10,000 is bequeathed to the alumni loan fund. The residue of the estate is to be divided between Miami University and the Cincinnati Museum Association, and it is said that each institution may receive \$200,000.

THE Addison Brown collection of plants offered to Amherst College by Mrs. Brown in memory of her husband, at one time a member of the class of 1852, has now come into possession of the college. Containing many thousands of specimens collected in the United States, Mexico, Porto Rico, the Hawaiian Islands and elsewhere, it is by far the largest accession ever received by the department.

PLANS have been drawn for the construction of four greenhouses, a heating plant, wells and windmills, and an underground piping system for irrigation purposes, on the new botanical garden for the department of botany of the University of Michigan. The old botanical garden east of the city with the 10,000 trees and shrubs which have been planted there, will be made into a tree and shrub park in about a year.

DR. HENRY C. COWLES, Dr. C. J. Chamberlain and Dr. O. W. Caldwell have been promoted to full professorships of botany at the University of Chicago.

DR. JULIUS STIEGLITZ, professor of chemistry and director of analytical chemistry in the University of Chicago, has accepted an invitation to give courses in chemistry at the University of California during the summer term that begins June 21 and closes on August 1.

PROFESSOR DANIEL STARCH, of the University of Wisconsin, will give courses in educational psychology and educational measurements at the University of Washington, Seattle, during the coming summer session.

At the University of Birmingham Dr. Douglas Stanley has been appointed to the chair of therapeutics, and Dr. L. G. Parsons to a newly created lectureship in infant hygiene and diseases peculiar to children.

DISCUSSION AND CORRESPONDENCE

THE FUNDAMENTAL EQUATION OF DYNAMICS

THE difference of opinion between Professor Huntington and myself is probably less than might be inferred from his recent communication.¹ I do not object to the use of the equation $F/F' = a/a'$, which indeed is a useful one. But it seems to me misleading to call this the fundamental equation of dynamics, because there is something equally fundamental that is quite independent of this equation—the fact that the mass of a body is one of the factors determining what acceleration it has under the action of a given force. The same fact is expressed by Professor Huntington in the words: "different bodies require different

amounts of force to give them any specified acceleration," which he refers to as "this central fact of dynamics." My view is that this "central fact" should receive explicit and quantitative statement in whatever equation or equations may be adopted for expressing the fundamental law of acceleration. The principle which such equations must express may be stated in different ways. In the review² which called forth Professor Huntington's comment I expressed the opinion that the method most intelligible to the beginner is to introduce at the outset the body-constant which was called by Newton *mass* or *quantity of matter*, and to make the fundamental principle a statement of the way in which the acceleration of a body depends quantitatively upon both the applied force and the mass of the body. The principle then takes the following form:

(a) *A force acting upon a body otherwise free would give it, at every instant, an acceleration proportional directly to the force and inversely to the mass of the body.*

The meaning is perhaps more clearly brought out by writing a definite proportion:

(b) *Forces F, F' , acting upon bodies whose masses are m, m' , cause accelerations a, a' such that*

$$\frac{a}{a'} = \frac{F}{F'} \cdot \frac{m'}{m}. \quad (1)$$

It is instructive to consider the following partial statements of the general principle:

(c) *If the same body is acted upon at different times by forces F, F' and if a, a' are the accelerations caused, then*

$$\frac{a}{a'} = \frac{F}{F'}. \quad (2)$$

ration of the statement (quoted with disapproval by Professor Huntington) that "an equation which results from comparing the effects of different forces upon the same body can not be regarded as a complete expression of the fundamental law of motion; it is equally important to compare the effects of forces acting upon any different bodies."

¹ The mere qualitative statement above quoted is no more satisfactory than the statement that "different forces acting at different times upon the same body cause different accelerations."

² SCIENCE, December 4, 1914.

¹ SCIENCE, February 5, 1915.

² These words seem to be a very definite corrobor-

(d) If bodies whose masses are m, m' are acted upon by equal forces, causing accelerations a, a' , then

$$\frac{a}{a'} = \frac{m'}{m}. \quad (3)$$

(e) If bodies whose masses are m, m' are acted upon by forces F, F' such that equal accelerations are caused, then

$$\frac{F}{F'} = \frac{m}{m'}. \quad (4)$$

Equations (2), (3) and (4) are all particular cases of (1), but it requires two of them to express the whole import of (1), and there is no reason for regarding (3) as more fundamental or more important than (3) or (4). Any single equation which may properly be called the fundamental equation of dynamics must be equivalent in import to equation (1).

This does not mean that it is never allowable or advantageous to use the less general equations; on the contrary, problems and illustrations falling under these special cases are undoubtedly helpful to students. But the object should be to lead up to an understanding of the fully general principle expressed above in paragraphs (a) and (b) and in equation (1).

When this principle is fully understood, it is seen that equation (1) enables us to determine the acceleration of *any* body of known mass due to the action of *any* known force as soon as we know the acceleration of *one* body of known mass due to the action of *one* known force. For practical use it is advantageous to express the general equation in a more concise form. It is readily understood that (1) is equivalent to the equation

$$a = k \frac{F}{m}, \quad (5)$$

in which k is a constant of which the value depends upon the units chosen for expressing acceleration, force and mass; and that the still more concise form

$$a = \frac{F}{m} \quad (6)$$

results if units are so chosen that *unit force acting upon unit mass causes unit acceleration*.

The foregoing is essentially the Newtonian explanation of the second law of motion as

interpreted by Thomson and Tait and accepted by other high authorities. In essential meaning there is no difference between this and the method advocated by Professor Huntington. The word mass is, indeed, avoided in his statement; but in recognizing the importance of the fact "that different bodies require different amounts of force to give them any specified acceleration" he recognizes the reality and fundamental importance of the body-constant which is usually designated as mass. By whatever name this constant may be called, it must play a part in the theory equivalent to that taken by mass in the equations given above. In Professor Huntington's presentation this part is taken by "standard weight," defined as the force required to give the body the acceleration 32.1740 ft./sec.² This does not conflict with the theory outlined above; in fact since the forces required to give different bodies a specified acceleration are by equation (4) proportional to their masses, standard weight as above defined may serve as a valid measure of mass. In explaining this method, however, it is important to make perfectly clear the fact that the quantity called standard weight is in reality the measure of a body-constant and is quite independent of gravity, in spite of the fact that it is given a name which is almost always associated with gravity. If properly safeguarded in this respect, Professor Huntington's method of developing fundamental principles is, I believe, logically defensible. Whether it meets the needs of beginners as well as that based upon the Newtonian treatment of mass may, however, be questioned.

To start with the notion of mass defined provisionally as "quantity of matter" has the same kind of advantage as starting with the "spring-balance" definition of force. Both definitions have a sufficiently definite meaning, gained from ordinary experience, to be of service in a preliminary explanation of the laws of motion. In comparing the masses of bodies composed of one homogeneous substance the significance of the words "quantity of matter" is indeed readily recognized, and it is distinctly helpful to generalize this notion even

though we must also recognize that any *general* method of comparing quantities of matter must employ either the laws of dynamics or some other physical law in which the same body-constant is significant.

Reflection upon what is really involved in the Newtonian laws soon shows, indeed, that the provisional definitions of force and mass are quite inadequate as a basis for a strictly logical explanation of the laws. It has long been recognized by writers who have attempted to formulate fundamental principles with full logical rigor that the definitions of both force and mass are implicitly involved in the laws of motion themselves.⁵ An analysis of the strict logical import of the Newtonian system would, however, be quite unintelligible to beginners, and a recognition of the soundness of such an analysis is no reason for dispensing with the aid of the more tangible notions of *quantity of matter*⁶ and *push or pull*.

While the method advocated by Professor Huntington is in my opinion sound in its essential features, the explanation of it in the paper⁷ to which he refers seems to encourage the erroneous notion that the laws or facts of terrestrial gravity form a part of the principles of dynamics. Although the definition of

standard weight quoted above is of course quite independent of gravity, in the paper it is given the form of a gravity definition: "The *standard weight* of a body is the force of gravity on that body in the standard locality." The reader is likely to miss the significance of the qualifying statement made elsewhere in the paper that the standard locality is any locality where g has the value 32.1740 ft./sec.²—a statement which makes the reference to locality and to the force of gravity wholly irrelevant as regards the real meaning of the quantity called *standard weight*.

It is to be feared, also, that the definition of "force of gravity" given in the paper encourages vagueness rather than definiteness in the force concept. The conception of force as a *push or pull*, exemplified by the pull which stretches a spring, is a very definite one. It loses its definiteness, however, unless the fact is kept in mind that *there is always some body that does the pushing or pulling*. When, therefore, it is said that a body is acted upon by a certain force, it is always pertinent to ask *by what body this force is exerted*. How is this question to be answered in the case of the "force of gravity" as defined in the paper? The definition is as follows:

By the "force of gravity" on a body, we mean simply the unseen⁸ force which gives the body, when allowed to fall freely from rest, in *vacuo*, in the given locality, the observed acceleration g . It is equal and opposite to the force required to support the body in that locality.

The question *by what body this force of gravity is exerted* is not answered in the paper, and an attempt to supply the answer leads to the conclusion that the definition is inconsistent with the conception of force as a *push or pull exerted upon a body by another body*. The "observed acceleration g " has a component that is not due to force at all, but to the fact that our base for estimating acceleration is the rotating earth. The body is not acted upon by a push or pull that is "equal and opposite to the force required to support the body"; if it were, a supported body would have no acceleration, while in fact it has an

⁸ Is the word "unseen" here intended to imply that there are forces which are visible?

⁵ Probably the most adequate formulation of the Newtonian laws from the point of view of strict logic is that given by W. H. Macaulay (*Bull. Am. Math. Soc.*, July, 1897). Mr. Macaulay's analysis makes it clear not only that the definitions of mass and force are implicitly contained in the laws themselves, but that the law of acceleration and the law of action and reaction can not be treated as independent, and further that the question of a base for estimating acceleration is of fundamental importance, since the laws, if true for one rigid base, will not be true for another which has any motion except a uniform translation with respect to the first.

⁶ Professor Huntington's statement that the mass concept is "a derived concept, both historically and practically" is hardly true in any sense in which it is not also true of force. At all events mass in the sense of quantity of matter has been treated as fundamental by many high authorities from Newton down. See the opening

⁷ paragraph of the "Principia."

⁸ *Bull. S. P. E. E.*, June, 1913.

acceleration even though at rest relatively to the earth.

Professor Huntington objects to the definition "force of gravity = attraction of the earth" on account of "complications connected with the spheroidal shape of the earth, the influence of the earth's rotation, etc." From what has been said above it is quite evident, however, that if the complications* connected with the earth's rotation are evaded by his definition it is only by a sacrifice of clearness in the force concept.

Clear thinking about the concept of force would seem to be promoted by the more usual method of distinguishing between *true* and *apparent* force of gravity; the former being the actual earth-pull on a body, the latter the pull or push exerted by a body upon its support. Each of these is a true force (a pull or push exerted by a specified body); to assume them equal is a first approximation to the truth. The reason they are not exactly equal can be explained rigorously when the student is in a position to understand the dynamics of circular motion; before that stage is reached it is sufficient to stop with the explanation which neglects the effect of the earth's rotation.

L. M. HOSKINS

THE NATURE OF THE ULTIMATE MAGNETIC PARTICLE

FOR many years scientists have agreed in ascribing the magnetic properties of bodies to the action of exceedingly small elementary magnets, but the nature of these ultimate magnetic particles has been an open question. The influence of temperature, chemical composition and other factors has received the simplest explanation on the theory that molecules, or possibly groups of molecules, are the ultimate magnetic particles. On the other hand the electron theory of magnetism, developed by Langevin, Curie, Weiss and others, seems logically sound and is the only theory

* The spheroidal shape of the earth introduces no complication whatever as regards the definition "force of gravity = attraction of the earth." It is not necessary to be able to compute the attraction in order to understand the definition.

which has successfully accounted for diamagnetism.

The recently developed method of determining the positions of atoms within a crystal by X-ray photography and the ferromagnetic properties of magnetite, hematite and pyrrhotite crystals suggested a direct experimental method of eliminating one or the other of these two theories. By comparing photographs taken through these crystals while magnetized and unmagnetized it can be determined with certainty whether or not the atoms have moved from their positions of equilibrium during the process of magnetization. We have obtained experimental results with magnetite and hematite which indicate that the atoms do not leave their positions of equilibrium during magnetization. These results are consistent with the electron theory of magnetism and prove conclusively that magnetism is not a molecular phenomenon.

REED COLLEGE

THE NEW GLACIER PARK

TO THE EDITOR OF SCIENCE: Referring to the pleasing intelligence communicated by Dr. John M. Clarke, in SCIENCE for March 12, relative to the new glacier park near Syracuse, a further note on the history of its investigation may well be added. It would seem that the earliest clear interpretation of the glacial stream channels about Jamesville came from a master of physiographic study who has strewn many seed thoughts by the way during the past forty years—Mr. G. K. Gilbert. The record is in "Old Tracks of Erian Drainage in Western New York," an abstract published in the *Bulletin* of the Geological Society of America, Vol. 8, 1897, pp. 285-286. Dr. Quereau's paper, which appeared in the *Bulletin* of the following year, cites Mr. Gilbert's interpretation by way of acknowledgment, and both papers have been followed by the full expositions of Professor Fairchild in the publications of the Geological Survey of New York.

ALBERT PERRY BRIGHAM

COLGATE UNIVERSITY

SCIENTIFIC BOOKS

A Monograph of the Molluscan Fauna of the Orthaulax Pugnax Zone of the Oligocene of Tampa, Florida. By WILLIAM HRALEY DALL, U. S. Nat. Mus., Bull. No. 90. Pp. xv, 173; Pl. 1-26. Jan. 21, 1915.

Collectors of curios and fossils alike have long known of the beautifully preserved specimens in the Tampa "silex beds" of Florida. But their chief interest, as the author of this monograph aptly remarks, "is not limited to their æsthetic beauty, nor their position as characteristic of one horizon in the series illustrating the evolution of life on the globe, but is of extreme importance as furnishing a key to the little-understood succession of the Tertiary beds which fringe the islands of the West Indies and the encircling continental shores of Mexico, Central America and northern South America. The Tertiary column of the coastal plain of the Gulf states being fairly well elucidated, the relative position of the deposits to the south can be determined if any one of them can be satisfactorily connected with a given horizon in the North American series. Such a connection is afforded by the fauna of the silex beds of Tampa."

This problem confronting the paleontologists of the New World is strictly analogous to that presented Mesozoic and Cenozoic workers in the Old, viz., correlating northern temperate faunas with widely differing ones of a more southern, tropical character. There, much progress is being made of late in the older Tertiaries by the use of organisms other than molluscan, especially Foraminifera, and a similar tendency will doubtless soon be shown in this country. Yet there, such forms as *Velates Schmiadelianus* have served well as indices of horizons in both the southern and northern provinces of Europe, and such characteristic types as *Orthaulax pugnax* are equally serviceable here, from the Panama Canal to Georgia. Incidentally we may note the author's attempt to designate other horizons by characteristic species, as, for example, in the upper Oligocene:

Zone of—	Former designation—
<i>Scapharca dodona</i>	Alum Bluff beds
<i>Cardium cestum</i>	Chipola marl
<i>Orbitolites floridanus</i>	Tampa limestone
<i>Orthaulax pugnax</i>	<i>Orthaulax</i> bed

It is certain that only by the study of such faunal zones we may ever hope to be able to correlate the widely scattered Tertiary deposits of the West Indies and Central America.

As regards the relations of the fauna of the *Orthaulax pugnax* zone Dall says:

Four species go back as far as the Claiborne sands, six are found in the Jackson Eocene, and seven in the Vicksburg. Eight come up from the *Lepidocyclina* zone, four have been recognized in the scanty fauna known from the Nummulitic zone, and one or two from the very imperfectly explored Chattahoochee fauna. Eight are known from the Tertiary of Santo Domingo, several of which are very characteristic of the zone. The two characteristic species of *Orthaulax* occur in the lower Oligocene of the Panama Canal Zone, and at least one of them has been obtained in Santo Domingo, Antigua, and Anguilla.

"Above the *Orthaulax* zone we find 51 of its species surviving in the *Cardium cestum* zone, but only 14 reach the zone of *Scapharca dodona*.

"Fifteen occur in extra-Floridian Miocene beds, but only three in the Floridian Miocene; 11 are found in the Pliocene of south Florida, and five in the Florida Pleistocene, while 23 survive in the recent fauna." Of the 313 molluscan species known from the *Orthaulax pugnax* zone, 90 are described in this monograph as new, while about 120 are refigured from the author's well-known Wagner Institute papers. More than half the remaining species described by various authors are discussed and re-figured.

Of special interest in this generally marine assemblage of species is the presence of 27 land and fresh-water forms, consisting, among others, of *Helix*-like, Bulimoid, Pupoid and *Planorbis* types. One new genus is described, viz., *Microcerion* "about midway between *Cerion* proper and the small Pupidae."

No sympathetic regard for generic names

that have been in use for many decades has prevented the author from relegating them to oblivion if some other name seem to him to be the correct one in accordance with the strict rules of biologic nomenclature. For examples, note the following:

Strophia changed to *Cerion*, *Vermetus* to *Vermicularis*, *Utriculus* to *Retusa*, *Pleurotoma* to *Turris*, *Fulgur* to *Busycon*, *Eulima* to *Melanella*, *Astraliun* to *Astraea*, *Crassatella* to *Crassatellites*, *Cylindrella* to *Urocoptis*, *Tornatina* to *Acteocina*, *Bulla* to *Bullaria*, *Turbinella* to *Xancus*, *Tritonidea* to *Cantharus*, *Sigaretus* to *Sinum*, *Pectunculus* to *Glycymeris*, *Lucina* to *Phacoides*.

Since the above changes are for the most part mere substitutions of a less well-known name for one in more general use, there can be no doubt that it becomes the most of us with less special training in molluscan nomenclature to follow Dr. Dall's lead in our future publications. However, in some instances the changes suggested are based on Bolten's publication, referred to as "Mus. Boltenianum, 1798," antedating Lamarck in "Prodrome" by one year; yet of that rare edition we have understood Dr. Dall to say that there are but four copies in existence, though recently Schorborn's republication (75 copies) renders the work more accessible to workers, at least in the vicinities of large libraries. To what extent the old masters were excusable for not possessing one out of perhaps a half dozen copies of a private work seems to us certainly a legitimate query. Nor does the number 75 strike us as rashly great in this early twentieth-century literature. The only change we sincerely regret is *Pectunculus* to *Glycymeris*, both names having become well established in the literature for very different types from those now proposed. However imperative the inexorable laws of biologic nomenclature may be as regards this matter, Blainville's use in "Man. Malac., Vol. I, p. 540, 1825, of the adjective *Phacoides* can not be regarded as furnishing a sound basis for "Genus PHACODES Blainville." However, so far as the undersigned is concerned, such matters are very

secondary in importance to the many statements and suggestions regarding matters of correlation and evolution. Note the artificiality of certain generic terms as brought out in Dall's discussion of the species *Vellorita floridana*. He says: "this fossil has the conchological features of the recent species, the *V. cyprinoides* of Asia, but the combination is one which is probably due to dynamic causes operating upon a species of *Cyrena*, and which might occur sporadically anywhere within the distribution of the genus *Cyrena*. The Asiatic or African forms have probably no more intimate connection with the American fossils than that thus indicated, and the same is true of the fossil *Batissa* from the Puget group and its South Sea analogues. The 'genus' *Hinnites* is another form in which it is unlikely that there is any genetic connection between the species occurring in different horizons except what is furnished by the genus *Pecten*, from which *Hinnites* species are probably mere sports."

Extremely valuable as a connecting link between the Jackson and Vicksburg fore-runners and the Recent *Busycons* is the new species figured as *B. stellatum* (Pl. 10, Figs. 7, 9). Noteworthy from a lithologic standpoint is the statement that silicification of the calcareous matter of the fossils exposed between tides is now going on. We heartily agree with the author in his dislike of the present usage of the term "formation." We have never understood why the taxonomy of geologic units should be other than that suggested by the International Geol. Congress, '89, i. e., Group, System, Series, Stage, with corresponding time units, Era, Period, Epoch and Age. Finally, as an interesting matter in methods of illustration, we have a chance to see in this monograph in juxtaposition some excellent pen-and-ink drawings by McConnell and the results of modern photographic methods in use by the U. S. Geological Survey. The latter are good, though sometimes showing a lack on the part of the artist of the finer essential features of the shell. This monograph must be regarded as a distinct and valu-

able contribution by America's foremost student of Cenozoic invertebrate paleontology.

PALEONTOLOGICAL LABORATORY,
CORNELL UNIVERSITY

Text-book of Physiological Chemistry. By OLOF HAMMARSTEN. Translation by JOHN A. MANDEL. Seventh edition. Wiley and Sons, New York.

Another edition of Hammarsten's "Text-book of Physiological Chemistry" is now available in English (translation by Mandel).

Outside of the material contained in the first two chapters of the last edition which now have been combined into one, the arrangement of the older editions has been retained. Chapter for chapter, almost every subject treated occupies very nearly the same number of pages as before. Nevertheless, this edition is far from being a mere reprint. The newer observations and references are usually to be found—sometimes in place of older observations (and references), but more frequently as additions. In the field of metabolism, a field always somewhat scattered and submerged in "Hammarsten," the new edition will prove disappointing to American students just as the older editions have been. Most of the facts are there, but it takes a brave and diligent student to find them.

The index is very full, but its usefulness to students is not so great as it might be because it still lacks expert systematization. The first subject that the reviewer happened to look up in the index was mucin; sixteen references are given, the first is entirely misleading and the most essential references are tucked away in the middle of the long list.

Index and all, however, American biochemists are always pleased to see one more edition of the book which more than any other is kept within reach for daily consultation.

ORTO FOLIN

NOTES ON ENTOMOLOGY

Two recent parts of Das Tierreich treating of the hymenopterous superfamily Proctotrypoides¹ are almost monographic in character.

Both are by the Abbey J. J. Kieffer and treat of almost 1,800 species in over 180 genera. An illustration is given of nearly every genus, and there is an introductory portion treating of the external morphology. Many of the species are from our country.

India is sufficiently distant from both Europe and America and its fauna has been sufficiently unknown to have been selected as the probable place of origin of many types of animals. Its insect fauna, however, is now becoming better known through numerous books; three have come to hand recently. One by T. B. Fletcher² deals with the insects of southern India. There is an introductory account of insects, and life histories of many species representing most of the families. A second large work is by E. P. Stebbing³ and is devoted to accounts of the life history of and the damage wrought by the forest beetles of India. Unfortunately it contains the descriptions of various new species. The third work is purely economic and treats of the pests of various crops.⁴ It consists of 84 leaflets with plates, mostly colored, of insect and fungous enemies of field crops.

Several microlepidopterists had shown that certain Tineid larvae are of different shape and habit at different stages of development. Trägårdh⁵ has investigated these forms and arranges them in two sections, the tissue eaters that bite and eat the parenchyma of the leaf, and the sap-feeders, that take only liquid. The former method is the more primitive, the

² "Some South Indian Insects," Madras, 1914, 565 pp., 440 figs., 50 pls.

³ "Indian Forest Insects of Economic Importance—Coleoptera," London, 1914; 648 pp., many pls. and text figures.

⁴ "Crop Pest Handbook for Behar and Orissa," Calcutta, 1913. Issued by Dept. of Agric. of these provinces.

⁵ "Contributions Towards the Comparative Morphology of the Trophi of the Lepidopterous Leaf-miners," *Arkiv Zoologi*, VIII., No. 2, 48 pp., 62 figs., 1915.

latter requiring special modifications of the mouth parts. Several species are sap-feeders when young, and in later stages become tissue feeders.

The first impulse, upon finding some strange new form of insect, seems expressible only in a new ordinal name. Dr. Silvestri has found some small forms (2 mm. long) in Africa and Malasia representing the newest order of insects, Zoraptera.⁶ The genus *Zorotypus* is based upon several species resembling young Gryllidae. They have enlarged hind femora, two jointed tarsi, head with distinct Y mark, no eyes, last joint of palpi enlarged, nine-jointed antennae, and short one-jointed cerci.

It is indeed refreshing to find a paper on the systematics of Culicidae that contains no new generic names. Mr. E. Brunnetti⁷ has studied the proposed genera of mosquitoes from the standpoint of the dipterologist and comes to the conclusion of Dr. Williston that most of these names are based on characters of no generic value in Diptera, and are therefore synonyms. Under *Culex* he places no less than 72 such names. The value of the various characters is considered, and tables are given to the valid genera; some names, however, still left in doubt. *Corethra* is regarded as forming a subfamily in the Culicidae.

We all know that an insect "bite" is not simply a puncture, but our first interest has been to find a remedy. Dr. J. H. Stokes⁸ however, has investigated the pathological and histological features of a "bite" and concludes, that, irrespective of pathogenic organisms, the insect introduces a toxic agent which produces considerable changes in the tissues near the "bite." This toxic agent is not injured by alcohol nor by dry heat, but is inert after treatment with hydrochloric acid. The history of a "bite" is divided into four

stages; the papular, the pseudovesicular, the vesicular or oozing stage, and the involution or subsidence.

A CASE OF ASSUMPTION OF MALE SECONDARY SEX CHARACTERS BY A COW¹

A PURE-BRED registered Ayrshire cow, named Dorothy of Orono (23010), belonging to the University of Maine, produced three calves, on dates as follows: September 17, 1909, September 10, 1910, February 24, 1912. On the lactation following the birth of the second calf she made a record of 12,426.4 lbs of milk and 450.75 lbs. of fat, and was admitted as No. 426 to the Ayrshire Advanced Registry.

After March 24, 1913, the cow never gave any milk. The udder rapidly shrunk to a very small size and the animal began to show the external characteristics of a bull. This change was very slight at first, but soon became much more marked. *After a lapse of 8 months the general external facies and the behavior of the cow were like those of a bull to a remarkable degree.* The neck had become thickened in its posterior parts, and had developed a well-marked crest, as is characteristic of a bull. If the cow had been so screened that only her fore-quarters and neck were visible, any observer would have unquestionably pronounced her a male. The assumption of male characters in these regions was complete and perfect. In the hind-quarters the change from characteristic female conformation in the male direction, while less striking than in the anterior parts, was still clearly evident. The udder shrunk away to a very small size. The hips and rump took on the smooth, rounded, filled-out appearance which is characteristic of the bull, but not of the cow.

The cow was slaughtered on February 18, 1914. Autopsy showed as the only gross ab-

¹ This is a preliminary abstract of a paper having the title "Sex Studies. VII. On the Assumption of Male Secondary Characters by a Cow Affected with Cystic Degeneration of the Ovaries," shortly to be published in the Annual Report of the Maine Agr. Expt. Sta. for 1915.

normality a simple cystic condition of the ovaries. Histologically and cytologically these cystic ovaries differed from the normal cow's ovary in but one essential respect, namely, that they had no corpora lutea.

The case described presents for consideration certain definite and clear-cut results bearing on the problem of secondary sex characters. These are:

1. This cow had been a perfectly normal female and had performed all the reproductive functions, both primary and secondary, of the sex.

2. It later assumed certain of the secondary characters of the male, both in respect of structure and behavior, with perfect definiteness, and, so far as the characters concerned go, completeness. This change was, for example, at least as complete and definite as any of those described by Steinach² following castration and transplantation of gonads.

3. The gonads of this animal, examined subsequent to the change in secondary characters, were exactly like those of a normal cow, save in the one respect that the follicles were not breaking and discharging ova, but were forming follicular cysts or becoming atretic, and because of this no corpora lutea were formed.

- (a) The interstitial secreting mechanism of these ovaries was absolutely normal, both in respect of number of cells, and the cytological characteristics of the individual cells.

- (b) The germinal mechanism was perfectly normal up to the point where ovulation should occur. Then it failed to separate the ova from the ovary.

- (c) The outstanding, and so far as we can determine the only significant, anatomical and physiological difference between the gonads of this abnormal cow and those of a normal one, consists in the fact that the former lacked any luteal tissue.

A detailed account of the case, with figures, will be given in the complete paper.

A NEW THEORY REGARDING THE FEEDING POWER OF PLANTS¹

THE feeding power of plants has been a subject of a great deal of investigation during the last half century. Undoubtedly mere casual observation of the growth of wild and cultivated plants led investigators long ago to surmise that there is a difference in the feeding power of different species of plants. Numerous carefully controlled experiments have repeatedly confirmed this idea. Of the important mineral elements needed by plants, sufficient phosphates in an available form are most often lacking in a soil. It is largely on this account that phosphates have generally been used in testing the feeding power of plants. Fortunately phosphates are also well adapted to this study. With the rapidly increasing use of phosphate fertilizers, the subject has become one of considerable economic importance, since it may be possible that with a proper selection and sequence of crops as regards their feeding power, the cheap insoluble phosphate fertilizers may be used with greater advantage.

It was formerly supposed that insoluble minerals were made soluble by plants through the action of various acids secreted by the plant roots. As is well known, later experiments, especially those by Czapek, have demonstrated that other than carbonic acid, plants normally excrete at the most, only minute traces of acids. There remains, however, no question that practically all plants excrete through their roots large quantities of carbonic acid. Lately some investigators have suggested that differences in feeding power may be due to differences in amount of carbonic acid excreted by the roots. Experimental data, however, lend little support to this view, and hence indicate that there must be something vastly more important in determining the feeding power of a plant. On reviewing the literature concerning the subject, and considering the data obtained in this laboratory, the writer was led to formulate the following hypothesis:

Plants containing a relatively high calcium

¹Publication authorized by the director of the Wisconsin Experiment Station.

oxide content have a relatively high feeding power for the phosphorus in raw rock phosphate. For plants containing a relatively low calcium oxide content the converse of the above is true. A calcium oxide content of less than one per cent. may be considered relatively low. Corn, oats, rye, wheat and millet belong in this class. A calcium oxide content of somewhat more than one per cent. may be considered relatively high. Peas, clover, alfalfa, buckwheat and most of the species of the cruciferae belong in this class.

The explanation of the above relation is made possible by means of the laws of mass action and chemical equilibrium. The reaction making the phosphorus in raw rock phosphate available to plants is one between carbonic acid and the tricalcium phosphate in the rock phosphate, which may be represented as follows:

As is well known if none of the products to the right of the reaction are removed from solution, the reaction soon reaches a state of equilibrium. If the di-calcium phosphate is continually removed but the calcium bi-carbonate only in part, then the reaction will continue a little farther, but also soon comes to a state of equilibrium due to the accumulation of the calcium bi-carbonate. When this point is reached, the further solution of the phosphate is prevented. This is the condition that obtains for such plants as are low in calcium oxide and hence do not absorb the calcium bicarbonate in the proportion to the dicalcium phosphate as given in the reaction. In such cases, the plants soon suffer for soluble phosphates. If both of the products to the right of the reaction are simultaneously and continually removed in the proportion given, then the reaction continues from left to right and there results a continuous supply of soluble phosphates along with soluble calcium bicarbonate. This is the condition that obtains, at least in part, with plants containing a high calcium oxide content, and hence such plants are strong feeders on raw rock phosphate.

In accord with other investigators the writer

has found that the use of ammonium nitrate or sulfate as a source of nitrogen in quartz plant culture work, greatly increases the availability of raw rock phosphate to plants which are normally weak feeders on this material. In the light of the present theory this is very satisfactorily explained as follows: Calcium bicarbonate being much more soluble in a water solution of ammonium salts than in water alone, it follows that the addition of ammonium salts allows the preceding reaction to continue from left to right to a much greater extent than if water alone is present. The addition of a salt in which the products of the reaction are more soluble has the same effect to a certain extent as is obtained by removing the products of the reaction.

With the theory² here proposed it is possible to predict from the calcium oxide content of a plant whether or not that plant in quartz cultures will be a strong or weak feeder on raw rock phosphate. Under soil conditions there are many subsidiary factors that influence the availability of phosphates, and hence under such conditions the relative growth of a plant can not be taken rigidly as a true index of its feeding power for the limiting element which is supplied in an insoluble form. Seeming deviations from the theory may result under such conditions. It is possible that with proper restrictions the theory can be applied to the feeding power of plants in a broader way, involving the use of other insoluble plant-food materials besides rock phosphate, and the general theorem could then be worded as follows: The feeding power of a plant for an insoluble substance depends primarily upon two conditions, viz., (1) the solubility of that substance in carbonated water and, (2) whether or not the plant removes from solution all the products of the solubility reaction in the proper proportion, so as to allow the solubility reaction to continue indefinitely.

With the theory here presented the writer

² Since writing this article the writer's attention has been called to a recent publication in *Zhur. Opytn. Agron.*, 15 (1914), No. 1, 54, by F. V. Chirikov, who from entirely independent work from this, has come to practically the same conclusion as the one set forth in this paper.

believes that the feeding power of plants is satisfactorily explained, without the intervention of other acids than carbonic. Since the failure to establish that plants excrete notable amounts of other acids than carbonic, some investigators, as previously stated, have suggested that the differences in feeding power may be due to differences in amount of carbon dioxide excreted. A careful consideration of available data lends little support to this idea. It seems rather that it is the efficiency with which the carbon dioxide is used, and not the differences in amount excreted by different species of plants, that determines whether or not a plant will feed strongly on an insoluble material.

The writer has in preparation a detailed article dealing with the feeding power of plants and the availability of phosphates.

UNIVERSITY OF WISCONSIN

THE SOCIETY OF AMERICAN BACTERIOLOGISTS: SYSTEMATIC BACTERIOLOGY

Under the supervision of H. A. HARDING

A Study of B. subtilis by Means of the Classification Card: H. JOEL CONN.

One hundred and thirty cultures of the *B. subtilis* type, isolated from soil, have been studied by means of the classification card adopted by the society. The definition adopted for *B. subtilis* is: a large, peritrichic, spore-producing rod, facultatively anaerobic in the presence of dextrose, liquefying gelatine, and growing vigorously on ordinary media without chromogenesis, producing a membranous more or less wrinkled growth on the surface of agar. Two questions have been considered: (1) Do the determinations called for on the card separate these 130 cultures into more than one species? (2) Does the same culture always give identical results upon repetition of the tests?

In answering the first question half of the determinations represented by the "Group Number" on the card were excluded because they are implied by the definition of *B. subtilis*. The determinations taken into account were the fermenta-

tion of sugars and glycerin, and the reduction of nitrates. The nitrate reduction determination gives quite clear-cut results and may serve to separate an infrequent nitrate-negative species from an abundant nitrate-positive species. The fermentation tests do not give such definite results. They suggest that the 130 strains do not differ from each other in fermentative powers, but give inconstant results with the present technique.

The second question was answered in the negative as regards the fermentation tests; the nitrate reduction test seemed more constant, but insufficient data is at hand to settle the matter.

These tests indicate that with our present technique different "group numbers" do not always indicate different species. One of the first steps needed in revising the card is to establish the best methods for making the various determinations.

Some Induced Changes in Streptococci: JEAN BROADHURST.

Various relatively simple physical and chemical factors (such as changes in temperature and differences in artificial media) differ greatly from such agents as saliva, intestinal extracts, and pure cultures of other bacteria, in their effects upon the physiological activities of selected strains of streptococci. The physiological effects of the former, especially in the various test media containing the sugars and the related substances suggested by Gordon, are mainly of a negative or inhibiting type, and apparently temporary only.

The changes induced by the latter factors (saliva, intestinal extracts, etc.) are, however, markedly different. They are changes in kind not in amount of reaction; they are active and usually include new powers, not merely the inhibition or occasional stimulation of earlier powers or capabilities, and often indicate a complete rearrangement of the fermentative complex. These induced changes have, so far, been practically permanent.

A Study of the Correlation of the Agglutination and the Fermentation Reactions among the Streptococci: I. J. KLIGLER.

Bacteria have evolved so little along gross structural lines that it is impossible to differentiate members of the same genus on a merely physical basis. We therefore resort to the more delicate criteria of protoplasmic constitution and physiological activity, in which direction remarkable differentiation exists. Tests for the finer structural differences of these organisms are found in their behavior to differential stains, such as the Gram stain, and to the immune substances in-

¹ Abstracts of papers presented at the Philadelphia meeting, December 29, 1914.

duced by them in the animal body. Their physiological activity is measured by the end products of their metabolism. Physiologically, bacteria, generally, have evolved in two main directions—one group possessing marked carbohydrate splitting properties, the other having developed the property of digesting various protein substances. The streptococci belong to the former division, showing but little tendency to proteolysis.

It appears natural enough to assume that the biologic activities of a cell would correspond with the chemical nature of its protoplasm. Yet such a correlation has not been worked out except in a few isolated cases. Among the streptococci such a correlation, if it exists, would be especially significant in that it would help to differentiate the various members of a genus that has puzzled many investigators.

The agglutination, fermentation and hemolytic properties of sixty strains of streptococci obtained from various pathological conditions, were studied, using four agglutinating sera having a titer of 800-1,000, and six carbohydrates and other fermentable substances as follows:

Disaccharides	{ Lactose
	{ Saccharose
Trisaccharide	Raffinose
Alcohol	Mannite
Glucoside	Salicin
Starch	Inulin

Only a limited number of the strains were agglutinated by the sera used. A definite correlation was, however, obtained between the agglutinative and fermentative characters. The serum produced by a strain of one fermentative group (the group that fermented salicin, for instance) agglutinated only cultures of its particular division and failed to agglutinate members of any of the other groups. No such correlation was obtained with the hemolytic property, members of one hemolytic group being agglutinated by the sera produced by strains from other hemolytic groups.

The results obtained indicate that a separation of the streptococci obtained from various pathological conditions into three fermentative types would coincide most closely with their natural relationship.

The groups suggested are:

1. Salicin fermenters only, generally hemolytic—*Str. pyogenes*.
2. Raffinose fermenters, salicin usually fermented, mannite always negative, generally produces a green colony on blood agar—*Str. solivarius*.

3. Mannite fermenters, generally ferment salicin, rarely ferment raffinose, variable in their reaction to blood—*Str. fecalis*.

The Filterability of B. bronchisepticus: with an Argument for a Uniform Method of Filtration:
N. S. FERRY.

The purpose of the paper was to place on record a series of filtration experiments with *Bacillus bronchisepticus*, described as the cause of canine distemper by Ferry in 1910, McGowan in 1911 and Torry in 1913.

The experiments were conducted as follows: The organism was grown twenty-four hours both on agar and in bouillon. The bouillon growth was filtered, undiluted, while the agar growth was taken off in bouillon and made into a suspension of about the same density as the bouillon culture. The method of testing the integrity of the filters was that described by Bulloch and Craw in the *Journal of Hygiene* in 1909, which depends upon the measure of the pressure of air as it is allowed to pass through the pores of the candles while immersed in water. The filtration was conducted at room temperature, one hour taken as the length of time for filtration, and three pressures were used; gravity, 15 lbs. (negative) and 225 lbs. (positive).

The experiments proved conclusively that the *Bacillus bronchisepticus* is a filterable microorganism. The work also corroborates the results of previous investigators with regard to the fact that the less pressure used the more easily will some organisms pass through the filters.

Some interesting possibilities were suggested by the outcome of this work. Since 1905, when Carre claimed he had produced typical symptoms of distemper in susceptible dogs from the filtered discharges of diseased dogs, the majority of writers have classified the etiology of canine distemper as a filterable, invisible or ultramicroscopic virus, and it is so described in many textbooks. The work of Ferry, McGowan and Torry with the *Bacillus bronchisepticus* tends to refute the statements of Carre.

The results of the present filtration experiments puts an entirely new light on the subject. If the *Bacillus bronchisepticus* is the cause of canine distemper, then the experiments corroborate the work of Carre. If the work of Carre was correct, and if the causative agent of canine distemper is a filterable virus, then the experiments point very conclusively to *Bacillus bronchisepticus* as the etiological factor and confirms the findings of the three previously mentioned investigators.

The author suggests that steps be undertaken for making out some uniform method of conducting filtration experiments of testing the efficiency of the candle and expressing or recording the results.

Influence of the Concentration of the Nutrient Substrate upon Microorganisms: ZAX NORTHERUP.

1. *Determination of the Influence of the Concentration of the Gelatin in Nutrient Gelatin, upon Liquefying and Non-liquefying Organisms.*—Gelatin media, having the same amount of other nutrient substances than gelatin, per unit volume were prepared, using 15 per cent., 25 per cent., 35 per cent., 50 per cent. and 75 per cent. gelatin.

Difficulties were met in the preparation of the highest percentage of gelatin on account of the thick sticky nature of the mass, but an excess of water was added to make the mixture homogeneous, this water being then driven off by evaporation on a water bath.

Pure cultures of both liquefying and non-liquefying organisms were plated on the different concentrations of gelatin.

On account of the extreme viscosity of the 75 per cent. gelatin it could not be plated in the usual manner; a thin film of the gelatin was spread over a sterile glass slide in a sterile petri dish and inoculated by spreading a small drop of a 24-hour culture of the organism on the surface of the gelatin.

The number, size and appearance of colonies were to be noted on the media of the respective concentrations.

In counting, the low power of the compound microscope ocular No. 1 and objective No. 7 was found to give counts 3-4 times as high as the ordinary counting lens.

The numbers of organisms developing on the plates are influenced to some but not to any marked extent, if the mechanical difficulties of inoculating the gelatin and pouring the plates are taken into consideration. The decrease or variations noted may be due only to experimental error.

The size of the colonies was found to be inversely proportional to the concentration of the gelatin. This was especially marked in the case of the organisms which are the most active in liquefying gelatin.

The type and appearance of the colonies were also found to be worthy of note. The subsurface colonies of both liquefying and nonliquefying organisms appeared like very fine gas bubbles distributed throughout the medium. The active

liquefying organisms began to show a rectangular instead of a concave depression in surface colonies on 35 per cent. and 50 per cent. gelatin, while with the slow liquefer a new type of growth, a stalagmite-like or apiculate growth, appeared on the 50 per cent. gelatin. This type of growth was noted in the 25 per cent. gelatin of colonies of the non-liquefying organisms.

B. typhosus was the only organism among the eight types used in the experiment which refused to grow on the 50 per cent. gelatin. However another trial might prove successful.

The different phenomena observed in the course of this experiment will most probably call upon the sciences of physics and of physical chemistry for their interpretation.

Several questions have been called forth by the results of this experiment and most of them remain as yet unanswered.

What part does the medium or substratum and what part does the organism play in the formation of the so-called characteristic growths which are obtained in solid media? What force or forces cause the variation in types of liquefaction produced by various proteolytic enzyme-forming organisms? Does the inherent nature of the organism or its secretions play the greater part or are physical or physico-chemical forces the greater factor?

Why is the size and the structure of the colony so markedly influenced by the media of increasing concentration? It is not due to osmotic pressure, as gelatin is a colloid and consequently will exert no osmotic pressure.

Is it due to the lack of water or is it due to some physical property of the gelatin, as surface tension, which is more evident in greater concentrations?

What force causes the colony in a nutrient gelatin of high concentration to show a rectangular depression when in ordinary nutrient gelatin the depression is concave?

In the liquefaction of ordinary nutrient gelatin what part does the force of gravity play?

An interesting occurrence was noted in the "plates" made with the 75 per cent. gelatin. Upon examining these plates, several days (exact period of time not noted) after they were made, the glass slides were found in very fine pieces as if crushed by a powerful force. This occurred in every case. The crushing of the slide was evidently due to the contraction of the highly concentrated gelatin upon cooling and solidification. Just how much energy it will take to crush slides by mechanical force is yet to be determined.

The determination of the various physical and physico-chemical forces will serve to give some idea of the factors which microorganisms have to overcome in growing in gelatin and similar media of high concentration.

This experiment was worked out by Mr. O. M. Grunit, a senior student.

Induced Variations in Chromogenesis: M. R. SMIRNOW.

Of the various biological characters of bacteria, one of the most interesting yet least important is that of pigment production. Though considerable efforts have been expended in the study of this function, little of real value is as yet available. It appears that this property is especially prominent amongst the saprophytic organisms, and depends to a greater or less extent, on certain conditions of environment which vary with different bacteria, and is, as a rule, more or less constant for the same organisms.

With the exception of *Spirillum rubrum* and possibly a few others, the chromogenic bacteria require an abundance of free oxygen, giving no pigment under anaerobic conditions of growth. Temperature also seems to determine pigment production of some bacteria, thus the *B. prodigiosus* will give no pigment at 37° C.

Perhaps the most important influencing agent on the function of chromogenesis is the medium on which the organism is grown. With other factors of environment constant, chromogenesis will vary with the medium employed. Gessard, for instance, has shown that the *B. pyocyaneus* will produce only a blue color, of a most beautiful shade, in a two-per-cent. solution of peptone, which may be increased in intensity by the addition of five-per-cent. of glycerin. When grown on egg-white or other albumen or on weak glucose media it would produce a fluorescent green. This same organism when grown on a five- or six-per-cent. glucose medium or on immune serum would give no pigment. He believes that phosphates are required for the production of the fluorescein.

Substances that enhance the value of culture media, in a general way increase also the pigment production. Other substances, as acids or alkalis, may diminish or even inhibit its production. Some organisms may give different colors on media of different reaction. Thus the *B. prodigiosus* gives a distinct yellow color on alkaline, and a violet-red on acid media.

In what manner the pigment is produced is not yet known. It is regarded that the property of pigment production keeps pace with other biolog-

ical characters, as enzyme formation. This, the writer does not feel to be correct, inasmuch, as will later be shown, he has succeeded in increasing the chromogenic properties of some bacteria with a coincident decrease of enzyme formation. Some of the higher forms of organisms give rise to pigment as a function closely related with their nutrition and may possibly be regarded as products of metabolism. In these cases the pigment is obtained from the medium and is stored up in the bodies of the cells, as in the case of sulphur bacteria. Or, it may be produced on certain media containing iron, as evidenced in the so-called iron bacteria, through the products of metabolism and the production of sulphide or iron.

Chromogenesis may be increased not only by growing the bacteria on more favorable media and environment, but also by the process of selection, transplanting each time from portions of the culture or from a colony that shows the most pronounced pigment.

Experimentally induced variations in the chromogenic properties of the *Staphylococcus pyogenes aureus* may be brought about by exposure to phenol or by growth in phenol, glucose, sodium sulphate or sodium chloride broth. Nine different strains of the *Staphylococcus* were used in the work here reported. Five of these were old stock cultures giving little or no color; the remainder were a few months old and showed a fair amount of pigment at the beginning of the experiments.

The organisms were grown in the above media for from six to ten weeks, being transplanted every three or four days during the entire time. They were then grown on potato and blood serum media for from 24 to 120 hours, and the effect on chromogenesis noted.

The increase of chromogenesis is brought about more readily by growing the organisms in phenol broth than by exposing them to 75 per cent. phenol solution and transferring on to agar. Of the nine strains used phenol markedly increased the chromogenic properties in six, Nos. 1, 2, 5, 6, 7, 8; slightly increased it in Nos. 4 and 9 and left No. 3 practically unchanged or even slightly diminished. Growth in dextrose, sodium chloride and sodium sulphate broth invariably decreased or left unchanged the quantity of pigment produced. Often almost a pure white growth of the various cocci, subjected to the growth in NaCl and Na₂SO₄ broth, would be seen when transferred to potato or blood serum.

An old stock culture of the *B. prodigiosus* was also used. This organism gave the slightest trace

of color at 20° C. at the beginning of the experiment. The organism was subjected to phenol only, beginning with a few minutes' exposure to a 0.75 per cent. solution and increasing as it became more resistant up to fifty or sixty minutes. Cultures were made on agar and grown at 20° C.

A striking increase in color production on all media resulted, the color becoming deeper and deeper until the maximum was reached at the thirteenth exposure. Up to the nineteenth exposure the color of each succeeding growth became most pronounced in 48 hours. From thereon, with increasing time exposures, the color production was slower, the color reaching its maximum in three or four days. Different shades of red were produced on different media. On agar, the color was deep brick red; on blood serum it had more of a scarlet hue; while on potato the color was somewhat variable and not as marked as on the other media. It was, however, on glycerin agar and glycerin potato that the most striking results were observed. The original strain gave no color on glycerin agar, and only a pale, delicate reddish color on glycerin potato. Transplants made from the phenol exposed organisms gave a brilliant cherry-red color on glycerin potato spreading to surround the entire surface of the medium. On glycerin agar, a dull cherry-red color was obtained.

In summing up what has been said concerning chromogenesis, it becomes evident that this faculty is more or less closely associated with the metabolic activities of bacteria, nutritive or otherwise. It varies with the strain and is more or less dependent on oxygen, temperature, and the medium used. An organism may produce more than one color at once and the same time or it may produce different colors, depending upon environment and the medium used, particularly the latter. Finally, chromogenesis may be varied through the agency of chemicals, as seen by the work here outlined, phenol generally increasing, and glucose, sodium chloride and sodium sulphate diminishing this function.

Induced Variations in the Cultural Characters of B. coli: M. R. SMIRNOW.

The same technique that was used in the experiments on chromogenesis was made use of here. In all, 21 different strains of the various bacilli of the colon-typhoid group were used, but this report is confined only to the *B. coli*, of which seven different strains were experimented on. All of these strains were obtained from the Museum of Natural History of New York through the kind-

ness of Dr. C.-E. A. Winslow, and were the stock Nos. 19, 44, 45, 46, 52, 57 and 95. The transplanting was carried out every three or four days over periods varying from one to three months, thus allowing from ten to thirty or more transfers. The results obtained in each set of experiments were rather constant, though not altogether so, inasmuch as some of the strains reacted quicker or different in the degree of the action at one time than another.

Control cultures were carried on in plain broth throughout the experiment. It might be stated at once that there were very slight variations between the original stocks and these control cultures, but no more than would be expected as normal variations. These were seen as slightly increased or decreased amounts of gas or acid formation, in time of coagulation, or slight changes in the growth on potato. At no time, however, were the biological characters markedly changed nor enzyme production completely inhibited simply by continual passage through broth.

Growth on Potato.—Dextrose seemed to have a special effect upon the character of growth of *B. coli* on this medium. Five of the seven strains showed at best only a slight yellow or a very light brownish growth on ordinary potato, with practically no discoloration of the medium. Very frequently, indeed, the dextrose-affected organisms would give the typical "invisible" growth seen with the *B. typhosus*. Both the original stock and the control showed the characteristic colon growth on this medium. This change was noted so many times that the explanation based on differences in the composition of the potato could be excluded. Three of these five strains also showed this change after exposure to phenol. One strain of the *B. coli*, not changed in this respect with either dextrose or phenol, showed this same variation after growing in either sodium chloride or sodium sulphate broth.

Action in Milk.—Both phenol and dextrose diminished the acid production and inhibited the formation of lab enzyme in three of the seven strains of the *B. coli*, either entirely or for a period of two weeks at least. These results were not seen with the use of the strong saline or sodium sulphate broth.

Fermentation of Sugars.—The results obtained with these substances on *B. coli* with reference to variations in sugar fermentations can be best seen in the accompanying charts. The most striking changes here also were seen in those organisms

exposed to dextrose and phenol. The former completely inhibited both acid and gas formation and all the sugars tested in three different strains. In two other strains dextrose varied the fermentation of the sugars as to amount of acid and gas formation, some of which were totally inhibited. Phenol inhibited these fermentations in all of the sugars in only one case, and in four other strains it at times diminished this reaction to the point of inhibition. Sodium chloride and sodium sulphate had less effect than did phenol, giving usually slight variations in amount of acid or gas produced with an occasional inhibition.

Inhibition of all the sugar fermentations in any one experiment was almost always accompanied by inhibition in the usual changes in milk, the characteristic growth on potato, and the formation of indol.

Variations in Indol Production.—The production of indol is regarded by many bacteriologists to be as important a biological characteristic of *B. coli* as its fermentations of the sugars, and is even thought to be of greater importance in its differentiation. This quality, however, under normal conditions, varies considerably in its quantity and time of appearance with most strains, and at times requires more delicate tests than the usual Salakowsky method for its determination.

In the experiments here reported it appears that of the variations induced in *B. coli* that of indol production is the first to take place, often disappearing in the third or fourth culture in dextrose broth. This does not hold however when the bacteria grow in the other media, as evidenced below.

Each strain of *B. coli* was grown in plain broth as control, in dextrose, phenol, sodium chloride and sodium sulphate broth and on potato. Thirty-five sub-cultures were made in all. Indol was tested for after the 10th, 15th, 25th and 35th transfers. The tests for indol were made by inoculating one loop of culture from the respective media to which each strain was subjected into standard peptone solutions, grown for seven days at 37° C. and then tested by the Salakowsky method. All the tests were done at the same time, using the same batch of peptone solution throughout the experiment.

All the controls, grown in plain broth gave good indol tests even after the 35th sub-culture. Those grown in dextrose broth gave none at the 10th sub-culture nor thereafter. In phenol broth the property of indol production seemed to be somewhat increased, judging from the intensity of the reaction. Sodium chloride and sodium sulphate and prolonged cultivation on potato practically ex-

erted no influence, or if any, showed but a slight inhibitory effect.

Experiments were then carried out to see how soon the property of indol production is interfered with by growth in three per cent. dextrose broth, and it was found that *B. coli* lost this property usually on the third and at times on the second transfer over a period of from seven to ten days. In one experiment sub-cultures were made every 24 hours, with a total disappearance of the indol tests in 48 or 72 hours in all the strains.

In order to exclude the possibility of interference in the indol test by the presence of three per cent. dextrose, several cultures in plain broth, also peptone, were made and grown at 37° for seven days. Dextrose was added to each of the cultures and then tested for indol. Positive tests were obtained in all, hence excluding any possibility of such interference by the presence of the carbobydrate.

Experiments were then carried out to determine the permanency of this change. The cultures in dextrose broth after the 35th transfer were taken and grown in plain broth, transplanting every day and tested on the seventh day of incubation. Four of the strains of *B. coli*, Nos. 44, 45, 46 and 52, gave slight indol reactions on the third transfer, No. 46 gave a good positive on the fifth transfer, but the others took five to ten more transfers before they could be called "+" or "++" positive. Nos. 57 and 95 took six transfers before a trace of indol appeared. No. 19, a very feeble indol producer in the control, remained negative up to the fifteenth transfer, at which time the experiment was discontinued.

In summing up then, it can be said that dextrose and phenol, particularly the former, cause partial inhibition or total disappearance of acid and enzyme formation in some strains of *B. coli*. These changes, together with the suspension of the production of indol and the characteristic colon growth on potato, make the *B. coli* approach if not entirely appear like the *B. typhosus* type organism. These changes have been noted time and again, but in varying degrees, in those strains that are susceptible to variations, but for some unexplained reason can not be regarded as altogether constant. Indol formation would invariably return when these altered bacteria were transplanted into plain broth at frequent intervals. Lab enzyme would also return in most of the altered strains, but not invariably so. The same can be said of the fermentative properties, but even to a less extent. Very often, however, these characteristics appear to be entirely done away with, the change

being permanent as far as could be made evident by sub-culturing into plain broth. In these cases observations were made up to two months after the last exposure to the influencing substance, making frequent transfers. There seemed to be no definite rule of reversion, no constant results and no relation between the reappearance of one enzyme and another. The reappearance of the fermenting enzymes in one sugar was not necessarily accompanied by those in other sugars. At times the fermentation of one sugar might have returned to nearly normal, while others might show little or no presence of gas with the same strain of *B. coli*.

Halophytic and Lime Precipitating Bacteria: K. F. KELLERMAN AND N. R. SMITH.

Of approximately 70 cultures isolated from the Great Salt Lake and from sea water from Florida and the Bahamas three types of organisms were secured. *Pseudomonas calois*,¹ a new spirillum and a new bacterium were isolated from the sea water. Closely similar varieties of species of *Spirillum* and *Pseudomonas* were found in water from the Great Salt Lake. Both in sea water and in the Great Salt Lake these bacteria are associated with the precipitation of calcium carbonate.

Relation of Crop to Bacterial Transformation of Nitrogen in the Soil: K. F. KELLERMAN AND R. C. WRIGHT.

Progress report upon continuation of work reported² previously.

The Influence of Hydrogen-ion Concentrations upon the Physiological Activities of Bacillus coli: WM. MANSFIELD CLARK.

Attention is called to the importance of hydrogen-ion concentration for the physiology of cells and to its importance for the solution of various problems of bacteriological chemistry. The experiments of Michaelis and Marcora upon the limiting hydrogen-ion concentration for *B. coli* have been elaborated and it is shown that although minor differences exist there is a limiting concentration at or above which all activity ceases. The same results were obtained with various cultures of the true colon bacillus. At the limiting

hydrogen-ion concentration proteolysis is inhibited. With increase in temperature the effect of hydrogen-ion concentration increases. The relation of this fact to the so-called thermal death point is pointed out.

An example is given showing the usefulness of the hydrogen-electrode in bacteriological research. By a study of the reaction of the medium at the close of the fermentation it was shown that by the use of *p*-nitro phenol a separation of the colon arogenes family could be accomplished. The groups so separated were rigidly correlated with the gas ratio.

Bacteria of the Colon Type Occurring on Grains:

L. A. ROGERS, WILLIAM MANSFIELD CLARK AND ALICE C. EVANS.

In an earlier paper it was shown that the colon bacteria of bovine feces belong to a very sharply defined type which was characterized by the production of a relatively small amount of gas composed of hydrogen and carbon dioxide in almost exactly equal parts. A study of the gas production by 166 colon-like cultures from grains as determined under carefully controlled conditions showed that these cultures could be divided into three physiological groups. These were (1) cultures giving a low volume composed of carbon dioxide only; (2) those giving a low volume and a carbon dioxide-hydrogen ratio of 1.06 and (3) those giving a high volume and a ratio varying from 1.90 to 2.90. The cultures producing a carbon dioxide only were also distinguished by the rapid liquefaction of gelatin. The low-ratio cultures, although agreeing with the fecal type in the gas production, were distinguished by the production of a yellow pigment. The 151 high-ratio cultures were divided into four types. Ninety of the 151 liquefied gelatin slowly, gave a carbon dioxide-hydrogen ratio of 2.50 to 2.80, produced a light cadmium pigment, failed to form indol from tryptophane, fermented saccharose and glycerine, and failed to ferment starch, inulin and adonite. Forty cultures failed to liquefy gelatin, gave a gas ratio of 2.20 to 2.50, and produced a light cream-colored pigment, did not produce indol from tryptophane, fermented saccharose, lactose and raffinose, but almost always failed to ferment the other test substances.

Two other groups, differing in their gas ratio and fermentation reaction were made but they included a relatively small number of cultures.

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE:

STANDARDS OF VENTILATION IN THE LIGHT OF RECENT RESEARCH

THE fact that the stagnant air of an occupied room becomes uncomfortable and makes those who are exposed to it listless and inert is a matter of common experience. When overcrowding in a close un-ventilated space reaches a certain point the results may even be fatal within a few hours, as in the Black Hole of Calcutta, the underground prison at Austerlitz and the hold of the ship Londonderry. Conversely the value of fresh air in the treatment of tuberculosis and other diseases is one of the fundamentals of medical and hygienic practise.

For the sanitarian it is necessary, however, to know something more than this general fact that bad air is bad. He must not only have some workable conception as to its operation, but also a more or less definite standard of permissible deviation from absolute purity.

In the earlier days of ventilation this was an easy task. It was natural to assume that the evil effects of the air of occupied rooms was due, either to lack of oxygen or excess of carbon dioxide, or to the presence of some specific organic poison of human origin—morbific matter or anthroptoxin, as this hypothetical substance was called. Of either of these changes the amount of carbon dioxide should serve as a fair measure, and a carbon dioxide standard was therefore confidently advanced by the older sanitarians as a practically all-suffi-

MSS. intended for publication and books, etc., intended for review should be sent to Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

cient measure of atmospheric vitiation. Even as late as 1910 in the excellent textbook of Hoffman and Raber one could read that carbon dioxide

is constantly being diffused throughout the air of the room, thus rendering it unfit for use. If this carbonic acid gas could be dissociated from the rest of the air and expelled from the room without taking large quantities of otherwise pure air with it, the problem of the heating engineer would be simplified, but this can not be done.

Yet Pettenkofer as long ago as 1863 showed clearly that carbon dioxide in itself is quite without effect in the highest concentrations which it ever attains in occupied rooms, and during the last fifteen years the researches of Flügge, Haldane, Hill, Benedict and other physiologists have rendered the older and more naïve view of the subject entirely untenable. Their studies indicate beyond any reasonable doubt that the more obvious effects experienced in a badly ventilated room are due to the heat and moisture produced by the bodies of the occupants, rather than to the carbon dioxide or other substances given off in their breath. Two fundamental experiments have been repeated again and again by these observers which alone would suffice to demonstrate, as Professor F. S. Lee has so well expressed it, that the problem of ventilation is not chemical, but physical—not respiratory, but cutaneous. These are, first, that subjects immured in close chambers, and exposed to the heat as well as the chemical products formed therein, are not at all relieved by breathing pure outdoor air through a tube; and, second, that they are completely relieved by keeping the chamber artificially cool without changing the air at all, and are relieved to a considerable extent by the mere cooling effect of an electric fan.

When the New York State Commission on Ventilation began its work last year it seemed that in spite of the establishment

of these broad principles the subject deserved further detailed study at its hands, particularly in regard to possible undetected effects of chemical impurities and in regard to the harmful influence of moderately but not excessively high temperatures which have received but little attention in earlier researches.

The work of the N. Y. State Commission was made possible by a generous gift of Mrs. Elizabeth Milbank Anderson through the N. Y. Association for Improving the Condition of the Poor, and the members of the commission are Mr. D. D. Kimball, Professor F. S. Lee, Dr. J. A. Miller, Professor E. B. Phelps, Professor E. L. Thorndike and the writer. The experiments so far conducted have been carried out in two experimental rooms placed at our disposal by the trustees of the College of the City of New York and now equipped so that the atmospheric conditions in one room can be very closely controlled by apparatus located in the other. In the observation room over one hundred different subjects in groups of four have been exposed for periods of from three and a half to eight hours a day for from one to eight weeks in each series of experiments, to known conditions of temperature and humidity and atmospheric vitiation and their physiological and psychological reactions and mental and physical efficiency observed and measured by the most exhaustive methods.

The results of our experiments to date have been presented before the American Public Health Association at its Jacksonville meeting and may be briefly summarized as follows:

Even quite extreme conditions of heat and humidity (86° with 80 per cent. relative humidity) had no measurable effect upon the rate of respiration; dead space in the lungs; acidosis of the blood; respira-

tory quotient; rate of digestion and rate of heat production (both measured by oxygen consumption); protein metabolism (measured by determinations of creatinine in the urine); or skin sensitivity.

On the other hand, the working of the circulatory and heat regulating machinery of the body was markedly influenced by even a slight increase in room temperature,

three room conditions were 37.41° , 36.99° and 36.73° , respectively. So the reclining heart rate rose in the hot room to a final average of 74 beats per minute and fell in the cool room to a final average of 66 beats (the warm condition not being comparable in this case). I use the terms hot, warm and cool throughout for the three temperatures and humidity combinations

FIG. 1. Relation between Room Temperature and Average Rectal Temperature of all subjects at end of day.

as, for example, from 68° to 75° with 50 per cent. relative humidity in both cases. In a hot room (86° —80 per cent. relative humidity) the rectal body temperature usually rose during the period of observation; in a warm room (75° —50 per cent. relative humidity) it remained on the whole about constant; in a cool room (68° —50 per cent. relative humidity) it fell. The average body temperatures attained under these

FIG. 2. Relation between Room Temperature and Average Reclining Pulse Rate of all subjects at end of day. (High value at 75° due to preceding physical work not duplicated at other temperatures.)

cited above. The increase of heart rate on passing from a reclining to a standing position became greater (by an average of 7 beats) during a sojourn in the hot room; while it became less by an average of 3 beats in the warm room and by an average of 7 beats in the cool room. The systolic blood pressure was slightly decreased in

the hot room (112 mm. against 116) and the Crampton value was markedly decreased, averaging 35 for the hot room, 45 for the warm room and 60 for the cool room.

in the total amount of work done in the hot room while with male subjects whose votes as to comfort showed no preference for the 68° over the 75° condition there was as

FIG. 3. Relation between Room Temperature and Average Difference between Increase-in-Pulse-Rate-on-Standing after reclining at end of period and similar increase at beginning of period.

FIG. 4. Relation between Room Temperature and Average Systolic Blood Pressure of all subjects at end of day.

Elaborate psychological tests of color naming, naming opposites, addition, cancellation, mental multiplication, typewriting and grading specimens of handwriting, rhymed couplets and prose compositions, all failed entirely to show any effect of even the severe 86°—80 per cent. relative humidity condition upon the power to do mental work under the pressure of a maximal efficiency test. Option tests of the inclination to do work, in which the subjects had the choice of doing mental multiplication or typewriting for pay, or of reading novels or doing nothing, showed a distinct lessening

much accomplished in the warm as in the cool room. We plan to repeat these experiments with women subjects who may probably be more susceptible to slight degrees of overheating.

The results with physical work (lifting dumbbells and riding a stationary bicycle) were much more definite. Again maximum effort tests showed no appreciable influence of room temperature, but when the subjects had a choice they accomplished 15 per cent. less work at 75° and 37 per cent. less at 86° than at 68°. These conclusions are quite what one would expect. Under pressure efficient work can usually be accom-

plished even under unfavorable conditions, but as a matter of common experience we find that the children in overheated school-rooms and the workers in overheated factories are listless and inactive.

servations are entirely negative, so far as the physiological and psychological and efficiency tests above mentioned are concerned. So long as the room temperature was the same it seemed to make not the slightest

FIG. 5. Relation between Room Temperature and Average Crampton Value for all subjects at end of day.

Experiments are now under way in regard to the influence of overheated rooms upon susceptibility to respiratory disease which promise to confirm the observations of Leonard Hill as to the changes in the mucous membranes which follow exposure to hot and dry air, while we find that the resistance of animals to artificial infection is very definitely lowered by chill following exposure to a hot atmosphere.

As to the effect of stagnant breathed air, contaminated by a group of subjects so as to contain on an average from 20 to 60 parts of carbon dioxide per 10,000, our ob-

FIG. 6. Relation between Room Temperature and Average Amount of Physical Work accomplished during the day, in summer and fall experiments.

difference to our subjects whether the air in the chamber was stagnant or was renewed at the rate of 45 cubic feet per minute per capita—except in one particular respect to be discussed more fully below.

It is perhaps not unnatural that these results, like the similar results of earlier investigators, should be popularly misinterpreted as meaning that ventilation of any kind is a needless luxury. When the first progress report of the commission was discussed in a New York paper under the headline, "Commission put its O. K. on

Stagnant Air," the curator of a large college building at once called upon the chief of the investigating staff to ask if he would be justified in stopping his fans. Such a conclusion as this is, of course, quite unjustified and most unfortunate in its effects. No scientific investigations can contradict or minimize the well-established results of experience as to the bad effects of poor ventilation and the beneficial results of fresh air. What physiological research has done is to show why bad air is bad—primarily on account of its high temperature and lack of cooling air movement, sometimes combined with high humidity. In our experimental rooms we can separate the factors of stagnation and overheating, but in practise an unventilated room (if at all crowded) is an overheated room. Ventilation is just as essential to remove the heat produced by human bodies as it was once thought to be to remove the carbon dioxide produced by human lungs.

Even the quantitative standards of air change established on the old chemical basis serve very well on the new physical one. For example, according to Pettenkofer's classical figure, which is a very low one, an adult gives off 400 British thermal units per hour. Let us assume that this heat must be removed by air entering the room at 60° and leaving it not above 70°. One B. T. U. raises the temperature of about 50 cubic feet of air by 1°, or the temperature of 5.0 cubic feet of air from 60° to 70°. Hence our average adult producing 400 B. T. U. will require 2,000 cubic feet of air per hour at 60° to keep the surrounding temperature from rising. An ordinary gas burner produces 300 B. T. U. per candle-power hour; therefore each such burner requires 1,500 cubic feet of air per candle power. These calculations, of course, ignore direct heat loss through walls

and ceiling which with a zero temperature outside may carry off the heat produced by 50 or 100 people. Ventilation provisions must, however, be based on the least, rather than on the most, favorable conditions. In crowded auditoria every bit of the 2,000 cubic feet of air is needed, and in many industrial processes where the heat produced by human beings and illuminants is reinforced by the friction of machinery and the heat from solder pots, furnaces, mangles, pressing irons and a host of other sources, even more will be required.

Furthermore, the recent studies of the New York State Commission suggest that there may, after all, be certain deleterious effects resulting from the chemical composition of the stagnant air of occupied rooms,

FIG. 7. Average Calorific Value of luncheons eaten with ample supply of fresh air and with no fresh air supply. In both summer and fall experiments the same conditions as to temperature and humidity prevailed through each series.

entirely aside from its temperature. As noted above, all the ordinary physiological and psychological tests failed to show any such effect; but in one particular we noted a difference in the behavior of the subjects exposed to stagnant and fresh air of the same temperature and humidity. In two of our series of experiments standard luncheons were served to the subjects in the experimental chamber and the amount on their plates was weighed. In one series the subjects consumed on the stagnant days an average of 1,151 calories and on the fresh-air days an average of 1,308 calories, an increase of 13 per cent. In a second series during colder weather, the average consumption was larger, 1,492 calories for the stagnant and 1,620 calories for the fresh-air days, an excess again for the fresh-air days, this time of about 9 per cent. The opinions of the subjects as to their comfort slightly favored the stagnant days, but it seems possible that odors of some sort, not consciously perceived by those exposed to them for several hours, may yet affect the appetite and hence the general health.

Even if further investigations should fail to confirm this result, it is my personal feeling that occupied rooms should be kept free from noticeable odors as a measure of public decency if not of public health. The cleanliness which results from the habit of bathing, except for the washing of the hands before eating, has, so far as I am aware, no important sanitary results. Just as the people who have been in a close room do not notice the odors which have accumulated during their occupancy, the person unaccustomed to bathing is unconscious of the effect produced, yet common decency rightly demands both bodily cleanliness and fresh air.

Recent research has, on the whole, strengthened rather than weakened the

arguments for ventilation. It has shown, however, that the physical quality of the air as well as its amount must be considered, and that a room supplied with air at the room inlet which will explode a thermometer registering to 125° (which happened to the instrument of one of my investigators in a New York City school) is not well ventilated, however many cubic feet of air may enter it.

The thermometer is the first essential in estimating the success of ventilation. Temperature standards must come into general use and a rise above 70° must be recognized as a sign that discomfort is being produced and efficiency decreased and vitality lowered. The carbon dioxide standard is still of value, however, as ordinarily a measure of the air change which is required to carry off both heat and odors; and the mechanical standard of thirty cubic feet of air per minute per capita as the amount necessary to supply in some way if an occupied room is to remain cool and fresh is still of general application.

The question of humidity is perhaps the most important one which remains to be solved before the practise of ventilation can be placed on a sure basis. A lack of humidity, as Professor Phelps has pointed out, makes hot air feel cooler and cold air feel warmer. Extreme dryness per se, however, at high or moderate temperatures, is believed by many to be in itself harmful, conducing to nervousness and restlessness and producing injurious effects upon the membranes of the nose and throat. There is, unfortunately, no solid experimental evidence upon this point, and this is one of the most important subjects which the N. Y. State Commission hopes to be able to study during the coming year.

It is a foolish empiricism which maintains that outdoor air as Nature makes it is necessarily the final word in air con-

ditioning. The task of applied science is to find out the best elements in a natural environment and to select the good without the bad.

Only as we succeed by the application of the methods of research in disentangling and measuring the various factors involved in atmospheric influence shall we be able to establish sound standards for the practical art of ventilation.

C.-E. A. WINSLOW

NEW YORK CITY

SOME ENGINEERING PROBLEMS IN VENTILATION

In the study of ventilation the engineering problems have not been overlooked. The criticisms directed against artificial ventilation have accomplished the double purpose of spurring to greater effort those who have been investigating the physiological problems relating to this subject and of causing the ventilating engineer to investigate the mechanical features of his work, with the intent of determining whether ventilation systems as installed meet all of the demands of good ventilation as now understood and whether they operate at a maximum of mechanical efficiency.

A careful review of the results in both fields is of surprising interest. The sanitarian formerly told us that carbon dioxide was a poison, that insufficient ventilation meant insufficient oxygen for breathing purposes and that we were endangered by "crowd poison" when in a mass of people. But little was said of temperature, less of humidity and nothing of air movement. We all believed that the chemistry of the air was vital.

The sanitarians, as a result of much experimentation, beginning about ten years ago, have proven to the satisfaction of all that there were other factors within the realm of ventilation of much greater impor-

tance than the chemistry of the air, notably its temperature, humidity and air movement, that is, the physical condition of the air.

The effect of excessive temperatures and humidities is especially well understood, as is the demand for constant air movement for the elimination of bodily heat and moisture. Less is scientifically known of the effect of cold and the effect of low humidities. The solution of these two problems is of vast importance.

Some there are who disregard altogether air quality, pinning their entire faith on proper temperature, humidity and air movement. Such a position is not justified by any reliable data now available. The cumulative effect of long exposures to stagnant air must be studied before safe conclusions may be drawn. Attention may be directed to the fact that in the experiments of the New York State Commission on Ventilation stagnant air decreased the appetite of the subjects 13 per cent. Is it not safe to assume that this is indicative of other, and possibly more serious, results. The report of Professor Winslow on the first year's work of the commission well states that this is "an observation which for the first time offers scientific evidence in favor of fresh air as compared with stagnant air of the same temperature and humidity." A final determination of the importance of air quality involves extended experimentation.

Window ventilation has been put forward as a panacea for all of ventilation's ills. But how little we scientifically know of its worth or its difficulties, especially those of air distribution, drafts, stagnant areas, temperature regulation, humidification, dust and economics.

But real advances have been made in solving the long-standing question of what constitutes good ventilation. The solution

of the remaining problems is but a matter of brief period. Coincidentally, splendid advances have been made in working out the mechanical problems of ventilation. The details of the installation of the boiler plant have been refined with a resulting increase in the efficiency of operation. New methods of steam distribution, such as the vapor, modulating and vacuum systems, have produced added comfort and economics. Temperature control systems have been devised and perfected to a point of reliability and durability. The individual duct ventilating system, providing air in the volumes and of the exact temperature required by each individual room under varying weather and other conditions, has been developed. Greater attention is paid to the diffusion of the ventilating air. More attention is now paid to the character of the installation and the materials used therein. Also much emphasis is being placed upon the measure of intelligence exercised in the operation of the plant, upon which both efficiency and economy depend. More effort, however, still needs to be made in these last two directions. Noisy heating and ventilating plants may be considered a thing of the past, for noise is indicative only of lack of skill in design or installation.

Ten years ago the mechanical efficiency of the ventilating fan customarily used was about 45 per cent. Now the best type of fan (the multi-blade) has an efficiency of 65 per cent. This advancement results in the saving of more than 30 per cent. of the power expenditure for ventilation. The efficiency of the driving device has also been increased, although in a less degree.

Possibly the most interesting, important and valuable recent addition to the equipment of ventilating plants is that of the air washer. Reference to air washing is made by Dr. D. B. Reid in his book on

"Ventilation" published in London in 1844 but it is really a product of the last ten years. Briefly it consists of a sheet-metal chamber in which the air is passed through a heavy mist and then through baffles or eliminator plates by which the air is so deflected that the entrained moisture is removed. The base of the washer constitutes a tank, into which the spray water falls and from which it is drawn by a centrifugal pump, usually motor driven. The pump forces the water through pipes and so-called nozzles which atomize the water in the spray chamber of the washer.

The manufacturers of these washers customarily guarantee the removal of 98 per cent. of the dust in the air. Practically all of the larger dust particles are removed but there is always a residue of fine dust which no washer will remove. In dry windy weather when there is a great deal of dust in the air, a large percentage of the dust is removed, but when there is very little dust in the air, as after a heavy rain, a small percentage of the dust is removed. Thus in Mr. M. C. Whipple's studies of the air washer it was found that the dust removal varied from 64 per cent. to 7 per cent. Certain dusts are not, to an appreciable extent, removed by the air washer. A standard method of testing air washers is needed and efforts are being made by the American Society of Heating and Ventilating Engineers to work out this problem.

The best results obtained in artificial humidification have been through the medium of the air washer. By the use of thermostatic devices an accurate control of the degree of humidification is obtained. The use of the evaporating pan containing a steam coil placed in the fresh-air chamber, the coil being under thermostatic control, also makes possible artificial humidification, but less satisfactorily.

The air washer may also be used for air

cooling. The evaporation of the water in the spray chamber will result in a lowering of the temperature of the air to the extent of 75 per cent. or more of the difference between the wet and dry bulb temperatures, often amounting to 10 to 15 degrees and sometimes to 18 to 20 degrees. This is due to the fact that water can not be evaporated without a supply of heat from some source, and in this case the heat is taken from the air. Considerable cooling can be done by the use of the same water recirculated by the pump and a greater degree of cooling may be accomplished by a continual supply of cold water. Purchased from the city mains this would be expensive, but if pumped from an artesian well the cost is small. Where a constant cooling effect is desired, independent of weather conditions, the use of a refrigerating plant in combination with the washer is necessary. The water tank is then increased in size and brine or ammonia coils, partially submerged and partially subjected to the falling spray, are installed. This is the most efficient method of positive artificial cooling, and is the most desirable method for ordinary purposes. Unfortunately it is expensive to install, involving approximately \$300 to \$600 per thousand cubic feet of air cooled. The cost of operation altogether depends upon the nature of the plant of which it is a part. If the plant is large, with exhaust steam to spare for use in an absorption refrigerating machine and the cooling water used in connection with the refrigerating plant may be used in the boilers and for domestic purposes in the building, the cost of operation is slight. Otherwise it may be roughly stated that the cost of cooling ten degrees during the summer is approximately equal to the cost of heating seventy degrees during the winter.

Cooling by evaporation of water alone has the disadvantage of increasing the

humidity, which is usually considered objectionable. But there is some evidence that in hot weather the lower temperature with higher humidity is preferred by workers. Mr. J. I. Lyle quotes, among others, an engineer who has done a great deal of testing laboratory work, in which the conditions were most exacting. He writes:

We can state that under the conditions shown by the readings below, the inside condition with a lower temperature, but a higher humidity, is more pleasant than the outside condition with higher temperature and lower humidity.

He illustrated by a comparison of outside conditions of 90 degrees dry bulb, 80 degrees wet bulb and 65 degrees relative humidity with inside conditions of 85 degrees dry bulb, 79 wet bulb and 77 per cent. relative humidity.

For ordinary ventilation work cooling at the expense of an increased humidity has been regarded as objectionable. It is said to produce a moist "clammy" feeling. Thus dehumidification becomes a part of artificial cooling, and the most expensive part, for the air must be cooled to that temperature at which saturated air contains the moisture necessary to give the desired relative humidity in the air when reheated to the ultimate temperature.

The use of the air washer has become almost indispensable in many industries, such as textile manufacturing, candy, macaroni, photographic and film making and in some processes of paper, tobacco, chemical, steel and plumbing fixture manufacturing.

Commercial considerations have done much to develop the use of the air washer in industrial fields. It is regrettable that humane considerations have done much less in this way in the general field of ventilation.

Possibly the most interesting study in the mechanics of ventilation is that of the

recirculation of the air used for ventilation. The New York State Commission on Ventilation, established through the generosity of Mrs. Elizabeth Milbank Anderson, has been actively interested in this work, and worthily so, for should it prove practical the cost of ventilating would be materially reduced. At one of the first meetings of the commission arrangements were made to carry on research work in this field. It was found that experiments along this line had been conducted by Dr. J. H. McCurdy, at the International Y. M. C. A. College Gymnasium, at Springfield, Mass., and at the Jackson School, Minneapolis, by Professor Frederic Bass. With the direction and support of the commission both of these experiments were continued under improved conditions.

In the former case use was made of the plant installed for ventilating the building, which was readily adaptable to the purpose.¹

This system included motor-driven supply and exhaust fans, heaters and an air washer of 36,000 to 40,000 cubic feet per minute capacity, or over 300 cubic feet per minute per occupant. It is such a system as is usually used for ventilating such buildings, and not an experimental plant, except that the volume of air used was larger than usual. By the manipulation of dampers the air could be supplied entirely from out-of-doors air, the air could all be recirculated or part outdoor air and part recirculated air could be used. The air could be washed or not, as desired. Experiments were made under all of these conditions, the subjects being the college students at exercise in the gymnasium, usually about 70 in number.

The carbon dioxide content of the air, the humidity and the temperature were carefully studied. Also studies of the efficiency and results of air washing were very care-

fully made by Mr. M. C. Whipple, of Harvard University.

The conclusion was reached that there seemed to be no appreciable difference between washed recirculated air and outdoor air similarly treated so far as bodily comfort is concerned. Naturally the proportion of carbon dioxide is greater when using the recirculated air, but no significance is attached to this fact. Mr. Whipple concludes "that recirculation provided a plentiful supply of air with no apparent sacrifice of wholesome properties, and that it is a safer source of supply than outside unwashed air."

During the winter of 1913-14 further studies were made at Springfield under the direction of the Ventilation Commission, the results obtained from recirculated air being equally as satisfactory as those obtained from the use of outdoor air. Window ventilation failed to give satisfaction.

Odors were not noticeable to those occupying the room during the use of recirculated and washed air, although sometimes barely noticeable to one entering from out-of-doors.

Conclusions were based upon the results of physiological examinations and comfort votes of the students.

In the second case a special plant was installed for one room of the school building, the pupils in the room serving as subjects. The air was introduced into the room at the top of each desk through a 2-inch vertical riser from a duct below the floor, emerging through a funnel-shaped, nearly horizontal orifice, at a velocity which was barely perceptible at a distance of two feet from the opening.² Air was also introduced at the top of the blackboards at the ends of the room. The air was exhausted through fifteen 3-inch openings evenly

¹ Described by G. F. Affleck in *Am. Phys. Educ. Review*, April and June, 1912.

² Described in paper read by Professor Bass before Am. Soc. H. and V. Engineers, July, 1913.

spaced at the ceiling of the room, and after being passed through an air washer, where it was cooled by the water about 15 degrees, it was returned to the room. The volume of air thus recirculated averaged 8.9 cubic feet per minute per pupil.

The results obtained in this room were compared with results in a room in the Adams School, the pupils in both rooms being of the same age, grade and general condition. The room in the Adams School was ventilated as is usual in the case of schoolrooms. The air was admitted through one opening above the blackboard and was exhausted through one opening near the floor on the same side of the room. The air was not washed and the volumes averaged 35.4 cubic feet per minute per pupil. The temperature averaged slightly lower and humidity slightly higher in the Jackson schoolroom.

The carbon dioxide averaged 12.5 parts per 10,000 in the Jackson School and 9.1 parts per 10,000 in the Adams School.

Dust counts showed 105,000 particles per cubic foot of air in the Jackson School and 225,000 in the Adams School. As a result of these experiments, covering a period of four months the conclusion is offered that it is impossible to demonstrate physical or mental deterioration due to the use of recirculated air. Neither is it possible to ascribe any discomfort on the part of the pupils or the teacher to this recirculated air.

The air washing, it is stated, was not sufficient to remove all odors, but they were reduced to such an extent that they were not offensive to persons occupying the room continuously, although noticed by persons entering the room.

In this experiment the problem of the use of recirculated air was combined with that of the use of a reduced volume of air delivered directly toward the face of the pupil. The two problems should be separately studied. More light on the effect of

recirculated air is desirable, as is the case with reduced volumes of air directly delivered and generally distributed.

In the case of one of these experiments the volume of air used was more than ten times that customarily used for ventilating purposes, and in the other case the volume of air used was less than one third that ordinarily used. Experiments with the standard and other volumes of air with the standard and diffused methods of introduction are desirable.

Studies along these lines are planned by the Ventilation Commission in connection with its experimental plant in Public School No. 51, the Bronx, New York City.

The economy of air recirculation was presented by the writer in the *Am. Physical Education Review* of December, 1913. Very marked economy was credited to recirculation. This claim was disputed by Evans in the June issue of the *Heating and Ventilating Magazine*, the claim being made that the cost of fresh cold water required for cooling and dehumidifying the recirculated air offset the saving in heat. Actual experience proves that such is not the case. Professor Bass states that water cost three cents per day during his experiments, which is vastly less than the amount stated by Evans. Dr. McCurdy states that some water was used for cooling, but even with 40,000 cubic feet of air per minute recirculated the cost of the fresh water used does not appear to have been a serious item.

It is manifest that a large amount of heat is saved, and this certainly warrants the most careful study of the problem of recirculation. Should it prove in every way satisfactory a great step in advance will have been made in the field of mechanical ventilation. But it may not be recommended as yet.

D. D. KIMBALL,
Member of New York State
Commission on Ventilation

CONDITIONS AT THE UNIVERSITY OF UTAH

At the request of the president and with the authorization of the council of the American Association of University Professors, the secretary of the association recently visited Salt Lake City and spent four days investigating the conditions at the University of Utah which have led to the resignation of sixteen members of the university faculty. The purpose and the limitations of the scope of the investigation are indicated by the following extracts from the secretary's letter to the president of the university:

The situation that has recently developed at the University of Utah has aroused much concern throughout the country among persons interested in the work of the American universities, and especially among members of the university teaching profession. It has, however, been difficult for those at a distance to be sure that they had correctly gathered the essential facts of the case from the incomplete and more or less conflicting *ex parte* statements which have appeared in newspapers and periodicals. In particular, the statements made upon the two sides of the controversy appear to have failed specifically to join issue upon certain points of interest. It has, therefore, seemed advisable to the president of the American Association of University Professors, Dr. John Dewey, to send a representative of that organization to interview yourself and others concerned, with reference to the matters in controversy; and to endeavor to secure as full and impartial a statement as may be of the relevant facts. It is perhaps advisable to explain the nature of the interest which the Association of University Professors takes in the matter. It is coming to be a well-recognized principle that the general body of university teachers is entitled to know, with regard to any institution, the conditions of the tenure of the professional office therein, the methods of university government, and the policy and practise of the institution with respect to freedom of inquiry and teaching. In the absence of information upon these points, it is impossible for members of the profession to judge whether or not the institution is one in which positions may be properly accepted or retained by university teachers having a respect for the dignity of their calling, a sense of its social obligations, and a regard for the ideals of a university.

It is, therefore, important to the profession that

when criticisms or charges are made by responsible persons against any institution, with respect to its policy or conduct in the matters to which I referred, the facts should be carefully determined in a judicial spirit by some committee wholly detached from any local or personal controversy, and in some degree representative of the profession at large. It is in this spirit, and for these purposes, that information is sought in this instance. What appears to be particularly desirable, in the present case, is a fuller and more definite statement than has yet been made public upon certain matters of fact which still remain not wholly clear, but which are, presumably, not incapable of ascertainment.

Any information of this sort which—with your assistance and that of others—I may be able to gather, will be laid before the council of the association, and probably also before a joint committee representing this and other organizations. My own report and the findings of the committee will, no doubt, if the council see fit, eventually be made public. We, of course, assume that the administration of the university is equally desirous that all facts in any way pertinent be thus fully made known, and submitted to the impartial judgment of both the academic and the general public.

We therefore venture to count upon your aid in this attempt to draw up a complete and unbiased summary of the circumstances of the case; this, we hope, may be of some service to the university as well as to our profession.

A report upon the case may be expected as soon as a committee of the association is able to consider the evidence brought together by the investigation of the secretary.

THE PACIFIC ASSOCIATION OF SCIENTIFIC SOCIETIES

The letter from Professor J. N. Bowman, secretary of the Pacific Association of Scientific Societies, published in *SCIENCE* for April 9, 1915, gives me the pleasant opportunity of placing on record certain interesting facts concerning the Pacific Association.

Men and women of science residing in the Pacific region were obliged to recognize that the demands upon time and money to enable them to attend the meetings of the American Association for the Advancement of Science, in the Eastern or Central States, were so severe as to be prohibitive to fully 99 per cent. of the 800 Pacific members. Inasmuch as the

American Association could not extend its influence efficiently over this region, because of the great extent of our country in longitude, and especially in order that the general scientific interests of the region should be united, it was determined by Professor Bowman and many of his colleagues in the universities and colleges of the Pacific region, and by others engaged in the applications of science, to establish an association of the principal scientific societies already existing in the Pacific area. The organization was effected some five years ago and the Pacific Association of Scientific Societies has been leading a vigorous and useful life. Annual meetings have been held in some of the leading educational centers, such as the University of California, Stanford University and the University of Washington.

Two years ago the council of the American Association for the Advancement of Science adopted the policy of organizing divisions of the American Association for the accommodation of those members who live at great distances from the chief centers of American population. In harmony with this policy, a Pacific Coast Committee was appointed to organize a Pacific Division. There was at once the question of the future of the Pacific Association, whose functions were in most essentials precisely those proposed for the Pacific Division. The men and the societies that were making a success of the Pacific Association were identically the men and the societies that would be expected to make a success of the Pacific Division of the American Association. Evidently there must be no duplication. The only practicable solution required that the Pacific Association should give up its identity and that the forces which were active in the Pacific Association should be active in the work of the Pacific Division. It was evident that the Pacific Division offered important advantages over the existing organization, in part from the resulting unification of general scientific interests throughout America. The problem was approached in a sympathetic and unselfish spirit by all concerned, especially by the officers and more active members of the Pacific Association, and by none more efficiently than by Secretary Bowman.

It has seemed to me that the Pacific Association of Scientific Societies, in giving up its existence, should have the principal incidents of its birth, activities and dissolution recorded in this manner as a matter of historical interest.

It should be recognized by every one, it seems to me, that the justification for moral and financial support afforded to scientific investigation rests finally upon the availability of the results for the welfare of mankind and the general progress of civilization. It is hoped that all men and women of the Pacific region who are sincerely interested in scientific research or in the spread of knowledge amongst the people will feel entirely at home in the Pacific Division of the American Association, for the encouragement of research and the dissemination of knowledge are pre-eminently, as every one knows, the functions of the Association and of all its Divisions. The sparsely populated condition of the Pacific region, which includes all United States territory lying west of the Rocky Mountains, as well as Mexico, British Columbia, Alaska and the Islands of the Sea, will unavoidably place a serious limitation upon the success of the Pacific Division unless a very large percentage of the scientists and friends of science in this region subscribe to its membership roll and join enthusiastically in promoting its plans. The yielding of generous support would on the contrary make success prompt and complete.

W. W. CAMPBELL,
*President American Association
for the Advancement of Science*

MOUNT HAMILTON, CALIFORNIA,

April 14, 1915

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

MINUTES OF THE COMMITTEE ON POLICY

MESSRS. NICHOLS, Pickering, Woodward, Cattell, Noyes, Humphreys, Fairchild, Paton and Howard, of the committee, met informally in the private dining-room of the Cosmos Club on Monday, April 19, 1915, at 7 P.M. After dinner, the meeting was called to order by the chairman, Mr. Nichols.

The minutes of the meeting of December 31, 1914, were read and approved.

After full discussion a number of resolutions were recommended to the council. These were adopted by the council and are printed in its minutes.

A letter from Ex-president Eliot was read in which he made certain suggestions relative to the possibility of preventing overcrowded programs at the meetings. On motion, the permanent secretary was instructed to arrange, so far as possible, all general interest items in the first, or general, part of the program in order that they may be easily consulted.

Professor Pickering, from the subcommittee on the Colburn Fund, of the committee on research, presented a report.

Professor Cattell presented a report from the Committee of One Hundred on Scientific Research.

Professor Pickering presented a report from the Committee on Expert Testimony.

L. O. HOWARD,
Secretary

MINUTES OF THE COUNCIL

The council met at 4.45 P.M., April 20, 1915, in room 37, new building of the National Museum, with Messrs. Fairchild, Nichols, Humphreys, Cattell, Kober, Shear, Taylor, Alsberg, Shantz and Howard present.

The meeting was called to order by the permanent secretary and Mr. Fairchild was asked to preside.

The committee on policy submitted a report through its chairman, Mr. Nichols, and, on recommendation of the committee, the following actions were taken by the council:

On nomination by the sectional committee of Section B, Professor E. Percival Lewis, of the University of California, was elected as vice-president of that section in place of Professor Frederick Slate, elected at the Philadelphia meeting, who was unable to serve.

On nomination by the sectional committee of Section H, Professor Lillian J. Martin, of Stanford University, was elected as vice-president of that section in place of Professor

George M. Stratton, elected at the Philadelphia meeting, who was unable to serve.

A resolution was adopted requesting Dr. William W. Campbell, president of the association, to prepare a formal address for the San Francisco meeting in addition to his regular address to be delivered before the association at the winter meeting of 1916-17.

In view of the desirability of rapidly increasing the membership of the newly founded Section M (agriculture), the council, on resolution, directed that the entrance fee of five dollars be remitted for the present calendar year to new members in the Section of Agriculture who may join from the following national societies having a qualification membership:

Society for Promotion of Agricultural Science, American Society of Agronomy.

The Society of Horticultural Science.

The American Society of Animal Production.

The Official Dairy Instructors' Association.

On motion, it was resolved to continue the subcommittee of the committee on research constituted at the Philadelphia meeting for consideration of the Colburn will fund.

Professor Roscoe Pound, of the Harvard Law School, was elected as a member of the committee on the amendment of the charter in place of Dr. Charles S. Minot, deceased.

An application from the Gamma Alpha regular program of the association when the Graduate Scientific Fraternity to allow a notice of its meeting to be inserted in the regular program of the association when the conventions of the fraternity were held at the same time and place as the meetings of the association was read and acted upon favorably.

On motion, the committee on policy was authorized to appoint a committee on the international relations of scientific institutions and scientific men.

The financial report of the permanent secretary for the fiscal year from November 1, 1913, to October 31, 1914, was read and, on motion, approved and ordered printed.

The permanent secretary reported briefly concerning the arrangements for the San Francisco meeting and announced that the

new volume containing the constitution, list of meetings, officers, committees, fellows and members was nearly ready for publication.

At 5.30 P.M., the council adjourned.

L. O. HOWARD,
Permanent secretary

SCIENTIFIC NOTES AND NEWS

MEMBERS of the National Academy of Sciences were elected on April 21, as follows: Dr. Charles Greeley Abbot, director of the astrophysical laboratory of the Smithsonian Institution; Dr. W. E. Castle, professor of zoology, Harvard University; Dr. G. Stanley Hall, president of Clark University and professor of psychology; Dr. Frank R. Lillie, professor of embryology, University of Chicago; Dr. Graham Lusk, professor of physiology, Cornell Medical School; Dr. Robert A. Millikan, professor of physics, University of Chicago; Dr. Alexander Smith, professor of chemistry, Columbia University; Dr. Victor C. Vaughan, professor of hygiene and physiological chemistry, University of Michigan; Dr. H. S. White, professor of mathematics, Vassar College; Dr. S. W. Williston, professor of paleontology, University of Chicago.

THE following have been elected members of the American Philosophical Society: John J. Abel, M.D., Baltimore, Md.; Edwin Plimpton Adams, Ph.D., Princeton, N. J.; Walter Sydney Adams, Pasadena, Cal.; John Merle Coulter, Ph.D., Chicago, Ill.; Whitman Cross, Ph.D., Washington, D. C.; William J. Gies, M.D., New York City; Philip Bovier Hawk, Ph.D., Philadelphia; John Fillmore Hayford, Evanston, Ill.; Emory Richard Johnson, Sc.D., Philadelphia; John Anthony Miller, Ph.D., Swarthmore, Pa.; Thomas Hunt Morgan, Ph.D., New York; William Fogg Osgood, Ph.D., Cambridge, Mass.; Raymond Pearl, Ph.D., Orono, Me.; Theobald Smith, M.D., Boston, Mass.; John Zeleny, Ph.D., Minneapolis, Minn.

A BANQUET to Dr. William Henry Dall, commemorating the completion of fifty years service to science was given at the Cosmos Club, Washington, on April 21. Dr. Dall responded to a series of toasts which were as

follows: Dall the Alaska pioneer, Dr. Alfred H. Brooks; Dall the anthropologist, Professor William H. Holmes; Dall the coast pilot, Mr. Isaac Winston; Dall the malacologist, Dr. J. Wayland Vaughan; Dall the zoologist, Dr. C. Hart Merriam; Dall the nomenclatorist, Dr. Ch. Wardell Stiles; Dall the poet, Justice Wendell P. Stafford; Dall the man, General A. W. Greely.

THE Royal Society of Arts has presented its Albert medal to Senator Guglielmo Marconi "for his services in the development and practical application of wireless telegraphy."

AT the annual dinner of the National Academy of Sciences, held on April 20, the Draper medal was presented to Dr. Joel Stebbins, professor of astronomy at the University of Illinois.

THE Jacksonian prize of the Royal College of Surgeons, London, has been awarded to Mr. Jonathan Hutchinson for his essay on the pathology, diagnosis and treatment of trigeminal neuralgia, and the John Tomes prize to Mr. J. F. Colyer for his work on comparative dental anatomy and pathology.

ACCORDING to a cablegram from Nish, Dr. Richard P. Strong, professor of tropical diseases in the Harvard Medical School, arrived there on April 24. He at once sat down to a long conference with the minister of the interior, Ljouba Jovanovitch, to discuss a plan of campaign against disease.

DR. SAMUEL T. DARLING, who was associated with General Gorgas for ten years on the Panama Canal, and who accompanied him to South Africa during his investigation of disease among the miners on the Rand, has resigned as chief of laboratory, and will investigate disease in the far east for the Rockefeller Foundation's international health commission. He left for Singapore via Liverpool on the *Adriatic* on April 21.

DR. FREDERICK H. GETMAN, of Bryn Mawr College, has resigned as associate professor of physical and inorganic chemistry and will open a private research laboratory in Stamford, Conn., at the close of the academic year.

C. M. JANSKY, professor of electrical engineering at the University of Wisconsin, has accepted an appointment on the jury of awards in the electrical group of the machinery exhibit at the Panama-Pacific International Exposition. He takes up his duties at San Francisco on May 3.

DR. K. HIRAYAMA, professor of astronomy in the University of Tokio, arrived at San Francisco on April 19 for two years' research study in the United States, principally at Yale University. He will inspect the observatories of the country and seek suggestions for the advancement of astronomical work in Japan.

THE Anglo-Swedish Antarctic expedition, under the leadership of Professor Otto Nordenskjöld, has been postponed until the war has ended.

DURING part of March and April, Mr. Robert Cushman Murphy, of the Brooklyn Museum, conducted field work in the Lower California desert. The principal object of the expedition was to study and obtain specimens of the pronghorn antelope. The material collected is to be used in a large exhibit illustrating plant and animal life of the arid southwest.

PROFESSOR J. S. HUXLEY, of the department of biology, Rice Institute, accompanied by Mr. W. M. Winton, biological fellow, and Dr. W. C. Graustein, instructor in mathematics, visited the Texas College, April 17-19, for an examination of local fossils gathered by Professor Francis from the Brazos Valley, as a preliminary to a collecting trip planned for later in the spring.

At the meeting of the New England Federation of Natural History Societies held last week in the building of the Boston Society of Natural History, Boston, the principal business was the reports of societies and the election of officers. More than twenty societies responded to the former with statements outlining their activities. The election resulted as follows: President, John Ritchie, Jr., Boston Scientific Society; vice-presidents, Arthur H. Norton, Portland Society of Natural History; Norman S. Easton, Fall River Society of Natural History; secretary, James H. Emer-

ton, Cambridge Entomological Club, Boston; treasurer, Miss Delia I. Griffin, curator, Children's Museum, Pine Banks, Jamaica Plain.

THE members of Sigma Xi in the University of Oklahoma have organized a club to be known as the Sigma Xi Club of Oklahoma. Dr. Irving Perrine addressed the first regular meeting, on March 29, on the subject of "Some Problems in Oklahoma Geology." It is the purpose of the organization to stimulate scientific research in the University of Oklahoma and the secretary, W. C. Allee, desires to get in communication with members of Sigma Xi who are planning to pass through Oklahoma.

PROFESSOR T. B. BRODIE, professor of physiology in the University of Toronto, will deliver a course of four lectures on "The Gases of the Blood" at King's College, London, on May 31, June 2, 7 and 9.

M. EDMOND RICAUX, of Boulogne, known for his work in geology and paleontology, has died in his seventy-seventh year.

DR. W. GRYLLS ADAMS, F.R.S., emeritus professor of natural philosophy and astronomy in King's College, London, died on April 10, at the age of seventy-nine years.

DR. OTTO N. WIRT, professor of chemical technology in the Technical High School at Charlottenburg, died on March 23, aged sixty-four years.

A NEW publication called the *Illinois Chemist* will make its appearance at the University of Illinois in May. Four chemistry organizations will cooperate with the chemistry department in issuing this new quarterly. It will publish among other things, information in regard to research work—results of experiments, notes on the work of alumni in the science. H. D. Valentine has been elected editor and V. W. Haag, business manager.

It is announced in *Nature* that the whole of the collections and library of the late Fortescue W. Millett, of Marazion and Brixham, have been acquired by Mr. Heron-Allen, and will be incorporated as a special section of the Heron-Allen and Earland collection, to which the collection of the late J. D. Siddall, of Chester, was also added recently. It is

hoped that this entire collection, numbering some 10,000 slides, and the library which accompanies them, will ultimately be incorporated with the Museum of Oceanography and Marine Biology, which it was the ambition of the late Sir John Murray to found. Broadly, his object was to form his collections of material and soundings into a department of the Natural History Museum in conjunction with the H. B. Brady and W. B. Carpenter collections, which are already there. The co-ordination of the Brady, Carpenter, Murray, Millett, Siddall, and Heron-Allen and Earland collections would form a reference museum of oceanic deposits and type specimens without an equal in the world.

The biological laboratory at Fairport is regularly open but the mess and special accommodations for temporary investigators will be available about June 15. There are opportunities and facilities for zoological and botanical investigations as well as for chemical studies relating to biological problems. Investigators desiring to occupy tables for any part of the season may communicate with the Commissioner of Fisheries, Washington, D. C., or the director of the station, Fairport, Iowa.

PROFESSOR LAWRENCE MARTIN, of the University of Wisconsin, is planning to conduct a party for summer field work in Alaska, stopping on the way at the Grand Canyon of the Colorado, the fault lines near San Francisco, and the California exposition. The trip is open to students from other universities and to teachers of geography and geology. It will start the middle of June or first of July and be gone about two months. Most of the time will be spent in camp along the fiords and in studying the glaciers of southeastern Alaska, including the Muir, Grand Pacific, Johns Hopkins and other ice tongues in Glacier Bay near the base of Mt. Fairweather (15,000 feet high), and the Taku, Norris, Eagle, Herbert, Mendenhall, Davidson, Denver, Sawyer, Dawes, Baird, Patterson, Le Conte and the Great Glacier of the Stikine. Examination of faults and other structures in the sedimentary rocks at the border of the coast range batholith, especially in relation to the origin of the

fiords. Visits to gold mines, placer deposits, copper mines, marble quarries, gypsum mines, salmon canneries, native villages with totem poles, etc. Possible ascent of Mt. Edgecumbe, a dormant volcano near Sitka. Trip over Canadian Coast Range on White Pass and Yukon Railway. Students without previous training may work for credit in elementary geology and physical geography, while advanced students can take up special problems in physiography, structural geology, stratigraphy and glacial phenomena.

In connection with the 109th annual meeting of the Medical Society of the State of New York, in Buffalo, this week, a program of public lectures was arranged as follows:

Monday evening, April 26, "Public Health." Professor C. E. A. Winslow, director, division of publicity and education, New York State Department of Health. Subject: "The New York State Department of Health and its Work." Illustrated. Dr. Charles J. Hastings, medical officer of health, Toronto, Ont. Subject: "What are We Doing to Improve our Race?" Dr. Francis E. Fronczak will preside.

Tuesday afternoon, April 27, "Child Saving." Julia C. Lathrop, chief of children's bureau, U. S. Department of Labor, Washington, D. C. Subject: "Why the Children's Bureau Studies Infant Mortality." Dr. Angenette Parry, New York City, president, Women's Medical Society of New York State, will introduce the speaker. The ladies' committee cordially invite all women to meet Miss Lathrop in the Reception Room of the Armory at five.

Tuesday evening, April 27, "Child Welfare." Dr. J. W. Schereschewsky, surgeon, Public Health Service, Washington, D. C. Subject: "The Relation of Heat to the Summer Mortality of Infants." Illustrated.

Wednesday afternoon, April 28, "Mentality of the Child." Henry H. Goddard, Ph.D., director, department of research, The Training School, Vineland, N. J. Subject: "The subnormal Child: Who is He and what must be Done for Him?" Illustrated.

Wednesday evening, April 28, "Safety First." Dr. Thomas Darlington, American Iron & Steel Institute, New York. Subject: "Welfare Work in Industry." Illustrated.

Thursday afternoon, April 29, "Prevention of Blindness." Edward M. VanCleave, managing di-

rector of the National Committee for the Prevention of Blindness, New York. Subject: "Saving Sight and Saving Citizens." Illustrated.

Thursday evening, April 29, "Conservation of Vision." Mr. Ward Harrison, illuminating engineer, Cleveland, Ohio, representing the Illuminating Engineering Society. Subject: "Right and Wrong Methods of Interior Illumination." Illustrated by booths.

THE Royal Geographical Society, as we learn from *Nature*, has received news of Sir Aurel Stein's explorations in Central Asia from April to November, 1914. The expedition started in April from Tunhuang, where it had halted to recruit after the trying campaign in the Lop-nor desert between Turfan and the northern boundary of Tibet. The cave temples of the Thousand Buddhas near Tunhuang were re-visited, and further interesting collections were made. The explorer followed the ancient wall for 250 miles, and found that it was constructed of fascines of reeds or brushwood, admirably adapted to check the wind erosion of the desert sands. Coins, pottery and metal fragments found near the surface made it possible to define the Chinese frontier posts with accuracy. Beyond the So-lu Hu Valley further remains of the same kind were found. While Sir Aurel Stein was hunting for remains of the Great Yuechi on Indo-Hun culture to the north, his surveyor, Lal Singh, examined the ruined town of Khara Khot, and proved that this could be no other than Marco Polo's "City of Etzina," where in ancient times travelers bound for Karakoram, the old Mongol capital, used to lay in supplies for the march across the great desert. Here many Buddhist remains were found, and it was ascertained that the ruin of the city was due to failure to maintain the irrigation system. When he despatched his report Sir Aurel Stein had planned to examine Buddhist ruins round Turfan, while his surveyor was to undertake the exploration of the little-known desert ranges of the Kuruk-tagh between Turfan and the Lop-nor depressions.

THERE has recently been issued by the Bureau of Standards, of the Department of Commerce, a paper describing a Wheatstone bridge designed with especial reference to flexibility

of use in measurements with resistance thermometers, and discussing the use thereof. The bridge is adapted to use with either the Siemens type or Callendar type of resistance thermometer, or with the potential terminal type of thermometer by the use of the Thomson double bridge method. The instrument is also arranged so that it may be completely self-calibrated. The 0.01, 0.001 and 0.0001 ohm decades are secured by varying, by means of dial switches, the shunts on three coils permanently connected in the measuring arm of the bridge. The sum of the resistances which are permanently connected is 2.5 ohms when the dials are set on zero, so that in order to measure resistances smaller than this a coil of 2.5 ohms is connected in the adjacent arm of the bridge. The entire electrical circuit of the bridge, coils, contact blocks, switches and connectors are totally immersed in an oil-bath thermostat, and special manipulating devices for the links and dials, etc., are provided. Details of construction are shown by photographs and briefly explained in the text. A new form of hermetically sealed coil, suitable for Wheatstone bridges, potentiometers, and similar apparatus, is fully described and record of its performance reviewed. Such construction eliminates the seasonal variations of resistance (with varying atmospheric humidity) found in coils of the usual types. The accuracy attainable with the bridge is such that resistances of one ohm or more can be measured to an accuracy of one part in 300,000 in terms of the unit in which the calibration is expressed. This corresponds to an accuracy of about 0.001 for measurements with the platinum resistance thermometer. Low resistances, the accuracy of measurement of which is limited by variations in contact resistances, may be measured to about three millionths of an ohm. This figure, rather than the one given above for accuracy, represents the precision attainable in measuring small changes of resistance such as are usual in resistance thermometry.

THE nation-wide study of the lumber industry, which is being made jointly by the Department of Agriculture and the Department of

Commerce, and the other industrial and technical investigations and experiments which have been carried on by the Forest Service in the last two years, were discussed at a conference of Forest Service officials at Madison, Wis., on April 14 to 17. The Forest Service Laboratory, the Washington Office of Industrial Investigations, and each of the seven National Forest Districts were represented at the conference by specialists. Among the subjects discussed were: Cooperation of the Forest Service with industries, lumber distribution in the United States, utilization of low-grade lumber and mill waste, adaptation of manufacturing and grading to specific classes of consumers, unification and standardization of lumber grades, study and development of general markets for National Forest timber, mill scale studies, including technical methods, tallying, etc.; lumber depreciation and the collection and compilation of lumber price data.

UNIVERSITY AND EDUCATIONAL NEWS

APPROPRIATIONS for two new buildings to meet the needs of the University of Ohio and for additional tracts of farm land west of the Olentangy have been voted through the finance committee of the lower branch of the legislature. These extensions would involve an expenditure of \$340,000. A domestic-science building to cost \$150,000 and a shop building for manual training to cost \$120,000 are provided. Ninety acres of land would be purchased west of the Olentangy River at a probable cost of \$70,000.

THE department of geology of Oberlin College is to move soon from the old building to a modern home in the science quadrangle. The museum has recently added much valuable data, including a collection of paleozoic fossils carefully worked over, identified and labeled; a collection of gold and silver, lead, bismuth and other ores from Utah and Idaho; a considerable number of topographic coast survey and other maps, and a large collection of wall pictures.

PROFESSOR C.-E. A. WINSLOW has been appointed to the newly established Anna M. L.

Lauder professorship of public health at the Yale Medical School. He will give up his connection with the New York State Department of Health and the Teachers' College to take up this work next fall, but will continue to act as curator of public health at the American Museum of Natural History.

PROFESSOR JAMES F. NORRIS, head of the chemistry department and of the department of general science of Simmons College, Boston, has accepted the position of professor of chemistry and director of the chemistry laboratories of Vanderbilt University, Nashville, Tenn.

At the Massachusetts Institute of Technology Associate Professor Henry G. Pearson is advanced to the grade of professor of English and he will be placed in charge of the department on the retirement of Professor Arlo Bates at the end of the present academic year. The following assistant professors are advanced to the grade of associate professor in their respective departments: Dr. Robert F. Bigelow, zoology and parasitology; W. Felton Brown, freehand drawing; Harold A. Everett, naval architecture and H. R. Kurrelmeyer, German. Instructor Henry B. Phillips is advanced to assistant professor of mathematics, and assistant instructors K. C. Robinson and John E. Bird are advanced to the grade of instructor in mechanical drawing. Miss Ruth M. Thomas, research assistant in organic chemistry, is advanced to research associate in the same department. The title of Professor A. E. Kennelly is changed from chairman to director of the research division of the department of electrical engineering.

MR. W. L. MOLLISON has been elected master of Clare College, Cambridge, in succession to the late Dr. E. Atkinson. He was second wrangler in the mathematical tripos of 1876, and was elected a fellow of Clare in that year.

DISCUSSION AND CORRESPONDENCE

THE PRESENTATION OF THE FUNDAMENTAL CONCEPTIONS OF MECHANICS

THE recent discussion in SCIENCE of the fundamental equation in mechanics has sug-

gested that perhaps some readers might be interested in a method of approach to the accurate physical conceptions of force and mass which I have been using recently with apparent success, and which differs, I believe, from that found in any text-book. I have come to believe that except for the very unusual student the disciplinary value of a dogmatic, mathematical presentation of mechanics is small, and that it is better to arouse and maintain interest by progressing from matters of every-day experience by as easy steps as possible, following largely the development of ideas which history has shown to be the natural one.

For the sake of brevity, I shall have to give the steps merely in outline. In fairness, then, the reader should remember that the work is supposed to extend over a period of several weeks, giving ample opportunity for the illustration of the various conclusions by numerous examples and problems, only a few of which can be suggested here.

Physics is largely a study of forces, and of the motions and strains due to forces. We will begin, then, with a study of common forces.

A. Force

1. *Introduction.*—Common experience. Muscular sensations. *Common effects of muscular exertion:*

- (1) Gravitational force overcome—weight raised;
- (2) Elastic force overcome—spring compressed or stretched;
- (3) Frictional force overcome—sled dragged;
- (4) Speed changed—ball thrown or caught;
- (5) Direction of speed changed—stone whirled in circle.

To study these it is necessary to be able to compare or measure forces.

2. *Measurement of Force.*—It is simplest to use the first effect, for preliminary work. It is natural to assume, in agreement with common experience, that the effort or force required to lift a number of equal blocks of iron is proportional to the number of blocks, or, more generally, to the volume of iron lifted. For

present purposes we will define the following as our units of force:

A *kilogram weight* (kg. wt.) is the force required to lift 128 c.c. of iron;

A *pound weight* (lb. wt.) is the force required to lift 3.55 cu. in. of iron.

We are now able to measure the forces required to produce the various effects mentioned above.

3. *Elastic Forces—Spring Balance.*—Stretch proportional to force. Hooke's Law. Calibration of spring balances for use where actual weights are inconvenient. Bending of a beam, stretching of a wire, twisting of a rod.

4. *Forces in Equilibrium.*—Two or more forces acting on a ring. Force table. Parallel forces acting on a beam. Non parallel forces acting on a derrick, etc. Definition of *vector*, *vector sum*, *moment of force*, *lever arm*.

Experimental laws:

(1) The vector sum of all forces acting must be zero.

(2) The algebraic sum of the moments of force about any axis must be zero.

Chemical balance.—Use to compare weights. Calibration of a set of brass and iron weights for use as standard forces.

5. *Frictional Forces.*—Friction is evidently equivalent to a resisting force equal and opposite to the force necessary to move the sled or other body uniformly along a horizontal plane. Study friction of wood on iron and wood on wood.

Experimental laws:

(1) Frictional force depends only slightly on the speed of relative motion. Kinetic and static friction.

(2) Frictional force is directly proportional to the force pressing the two surfaces together. $F = \mu P$. Define coefficient of friction.

(3) Frictional force is independent of the area of contact.

(4) Frictional force varies with the nature of the surfaces involved.

(5) A body started with a certain initial speed s_0 is brought to rest in a distance which is inversely proportional to the coefficient of friction. This suggests that on a perfectly smooth horizontal surface ($\mu = 0$), a body would keep moving with constant speed.

Before we can determine the effect of a constant unbalanced force in changing the motion of a body, we must study some simple types of motion.

6. *Some Simple Types of Motion.*—(1) *Uniform motion* in a straight line with constant speed. Define velocity. $d = st$.

(2) *Constantly changing speed, linear motion.* Define acceleration of speed. Derive formulas: $s = at$; $d = \frac{1}{2}at^2$; etc.; and $s = s_0 + at$; $d = s_0t + \frac{1}{2}at^2$; etc.

(3) *Parabolic motion*, combination of (1) and (2) at right angles. Formulas.

(4) *Uniform circular motion.* Constant speed but constantly changing velocity. Derive $a = s^2/r$. Distinguish *tangential* from *centripetal* acceleration.

7. *Type of Motion Due to a Constant Gravitational Force.*—(1) Atwood's machine, balanced forces; speed constant.

(2) Atwood's machine, small unbalanced force; $d \sim t^2$; positive acceleration.

(3) Atwood's machine, small retarding force; negative acceleration.

(4) Ball rolling down an inclined plane, or Fletcher's apparatus; $s \sim t$, $d \sim t^2$; acceleration constant.

(5) Water jet against blackboard, parabolic path; $d \sim t^2$.

(6) Ball rolling off table; measure g . Same for all bodies.

Conclusion: The motion produced is one with constant acceleration.

8. *Variation of Acceleration with the Force Acting on a Given Body.*—(1) Atwood's machine, various small unbalanced forces.

(2) Frictionless carriage on smooth horizontal plane.

Conclusion: The acceleration is directly proportional to the force.

9. *Measurement of Force Required to Give Centripetal Acceleration to a Given Body.*—

(1) Swing 50 or 100 gm. on the end of a rubber band or spiral spring and determine the stretch during rotation at a fixed rate. Measure the gravitational force required to produce the same stretch. Compute the centripetal acceleration and show that the force required to

produce it is to the weight of the body as the centripetal acceleration is to the acceleration of gravity.

(2) The centripetal force in the case of a mass rotating in a horizontal plane and free to slide along a rod may be measured directly by the weight required to produce the acceleration. Make the same computation as in (1).

Conclusion: The unbalanced force required to produce centripetal acceleration is equal to that required to give the same body an equal linear acceleration. Combining this with the conclusion of §8 we see that the acceleration produced by an unbalanced force acting on any given body is proportional to the force and is in the direction of the force, whether it is tangential or centripetal.

10. *Nongravitational Forces, Magnetic, Electric, Frictional, etc.*—Can be balanced by gravitational forces; produce the same effect when unbalanced; can be measured in terms of the gravitational force which will balance them or which will give the same acceleration to the same body. From our experience with gravitational forces we generalize and assume that whenever a body is being accelerated it is being acted upon by an unbalanced force; and if the known forces acting on the body are insufficient to account for its acceleration, we immediately postulate the existence of another force and experiment to find out what physical properties of the body in question and of the other bodies concerned, determine the amount of the force.

We have studied the relative effect of various forces upon the *same body* and arrived at the important generalization that whether the acceleration produced be tangential or centripetal, it is proportional to the force and in the direction of the force. We will not study the effect of the same force on various bodies.

B. Inertia or Mass

11. *Introduction.*—The fact that force is necessary to change the velocity of any body implies a tendency to persist in uniform motion and to resist a change of motion. This property of bodies is called *inertia*. The easier it is to accelerate a body, the less its inertia, of

course. So it is natural to assume that the inertia of any body is proportional to the force (F) required to give it unit acceleration, or since acceleration is proportional to force and since the acceleration produced by unit force would be $1/F$, this is equivalent to assuming that inertia is inversely proportional to the acceleration produced by unit force.

12. *Inertia of Different Volumes of Iron.*—

(1) Two carriages carrying two or three equal volumes of iron, accelerated toward each other by a stretched rubber band.

(2) Atwood's machine, same force, different volumes of iron.

Conclusion: Acceleration is inversely proportional to the volume of iron for the same force; therefore inertia is directly proportional to the volume of iron or to the amount of iron.

13. *Inertia of Equal Volumes of Various Substances.*—Assume that two bodies have the same inertia when the same force gives them the same acceleration. Using the same apparatus as in §12, we find that the ratio of the inertias or masses of any two bodies is equal to the ratio of their weights (at a given point on the earth).

14. *Units of Mass.*—Kilogram, gm., pound.

15. *Falling Bodies.*—Since the force acting is proportional to the mass of each body, the acceleration must be the same for all. This conclusion agrees with experiment.

C. Fundamental Law of Mechanics

16. *Summary:*

With same mass: $a_1 : a_2 = F_1 : F_2$.

With same force: $a_1 : a_2 = m_2 : m_1$.

With same acceleration: $m_1 : m_2 = F_1 : F_2$.

Combining these: $m_1 a_1 : m_2 a_2 = F_1 : F_2$.

17. *Fundamental Law.*—When any body is acted on by an unbalanced force, the acceleration produced is in the direction of the force, is proportional to the force and is inversely proportional to the inertia of the body acted upon.

18. *Gravitational Units of Force.*—Kg. wt., lb. wt. The units we have been using. If force is measured in kg. wt., mass in kg., and acceleration in cm. per sec. per sec. then

$$a = gF/m,$$

where g is the acceleration of gravity. The same equation holds for lbs. wt. and lbs. and ft. per sec. per sec. Variation of g with distance from center of earth. Units not absolute.

19. *Absolute Units of Force.*—Dyne, poundal. Independent of gravity. Simpler equation $F = ma$.

20. *Application to Various Special Cases.*—Atwood's machine, inclined plane, etc.

21. *Definition and Discussion of Momentum, Impulse, Work and Energy.*

I shall be very grateful for any suggestions in regard to the above outline, especially from those who are willing to concede that a departure from our present dogmatic method of presentation is advisable.

GORDON S. FULCHER

WISCONSIN UNIVERSITY

April 1, 1915

GET THE UNITS RIGHT

PROFESSOR A. GRAY in a recent lecture on Kelvin's work in gyrostatics, says:

It is always a good thing to get down to numbers and it is a most healthful mental discipline to be forced to get the units right.

The force of this remark is apparent in following the discussion in SCIENCE relative to the best expression of the fundamental equation in mechanics. Professor Kent criticizes Professors Huntington and Hoskins, objecting to the form of the equation $F = ma$. He rightly says:

The equation is not true in the ordinary English system (foot-pound-second) until it is hybridized by valuing either F or m in some other unit than pounds (poundal or gee-pound) or a in gravitals (instead of feet) per second per second (1 graval = 32.174 feet) or else the letter m is explained as not being quantity of matter in pounds but only the quotient or ratio W/g . Neither is it true in the metric kilogram-meter-second system. . . . It is of course true in the dyne-centimeter-gram-second system but this system is only used in higher physical theory and it should not be inflicted on young students.¹

¹ SCIENCE, Vol. XLII, No. 1055, p. 424.

Now what is the difficulty with the dyne-C.G.S. system and why not inflict it on the young? What is the present system, if not an infliction?

At Blue Hill Observatory we have for some time been expressing temperatures in degrees absolute, pressures both atmospheric and vapor, in kilobars or kilodynes, and rainfall in millimeters. Dr. Shaw, of the British Meteorological Office, has since May 1, 1914, published rainfall values in the daily weather report in millimeters and beginning January 1, 1915, the millimeter is used in the weekly and monthly weather reports. In nearly every part of the world except the United States the millimeter has supplanted the inch as the unit of rainfall measurement. Of course it will be adopted here before long. As Shaw points out, aside from the advantage of using a unit generally adopted, the unit of rainfall 0.01 inch used to define a rain day has been most unsatisfactory. A fall of 1 mm. (0.04 inch) is a much fairer definition and as a matter of fact we have had to publish this in addition to the former.

From the point of view of the engineer, the use of the millimeter facilitates computation and realization of the amount of water available over a given area. A millimeter of rainfall means a liter of water per square meter.

Any one who has lived in the western part of the United States and recalls the various miners' inches for measuring water depth and flow will realize that it would be far from being an infliction to have the C.G.S. units come into general use in engineering practice.

It is not so difficult to break away from the old units as may be imagined. A year's constant use of the C.G.S. units makes one feel like saying, when reading of inch measurements, "Inch, inch? Where have we met that term before?"

ALEXANDER MCADIE

HARVARD UNIVERSITY

A SPURIOUS CASE OF MULTIPLE HUMAN BIRTHS

In the *Boston Medical and Surgical Journal* for September 28, 1872, under the head of *Medical Miscellany* occurs the following item:

Eight Children at a Birth.—On the 21st of August, Mrs. Timothy Bradlee, of Trumbull County, Ohio, gave birth to eight children—three girls and five boys. They are all living, and are healthy but quite small. Mr. Bradlee was married six years ago to Eunice Mowery, who weighed 273 pounds on the day of her marriage. She has given birth to two pairs of twins, and now eight more, making twelve children in six years. Mrs. Bradlee was a triplet, her mother and father being twins, and her grandmother the mother of five pairs of twins.

This case has been quoted often both in general texts, such as Gould and Pyle, "Anomalies and Curiosities of Medicine," 1897, p. 153, and in special papers, such as Wilder, *American Journal of Anatomy*, Vol. 3, p. 393, 1904. From the Prussian statistics gathered by Veit, it has been shown that twins occur on the average once in 88 births, triplets once in 7,910 births and quadruplets once in 371,126 births. Cases of five or six children at a birth are well authenticated, but are so rare that no statistical statements concerning them can be made. Gould and Pyle, in commenting on these instances, declare that all cases thus far reported of more than six children at a birth are to be regarded as of very doubtful value. To this category belongs that of Mrs. Bradlee already quoted. As this instance is of comparatively recent origin, it seemed possible to learn something of its authenticity. A letter was therefore addressed to the county clerk of Trumbull County, Ohio, inquiring about the case, and through the courtesy of that official the following reply was received.

M. B. TAYLER,
CLERK OF COURTS,
TRUMBULL COUNTY
WARREN, OHIO, March 30, 1914

MR. G. H. PARKER,
Cambridge, Mass.

Dear Sir: I reply to your letter of the 24th inst., in regard to the item in the medical journal, would say that after inquiry I am informed that there is no truth in the statement. It seems that a practical joker of those days went into one of the newspaper offices here and set up an article which he succeeded in having printed in one or two copies of the paper and then took the article out and distributed the type in their proper places, and se-

curing the copies which had the article in, sent the same to a New York paper thinking he had accomplished a great joke. This is practically all the information I can obtain in regard to the matter but can state that there is no truth or foundation in the report whatever.

Very truly yours,
(Signed) M. B. TAYLER

It is clear from this reply that the case of Mrs. Bradlee, so far as the number of children is concerned, is spurious and ought to be dropped from the list of authenticated multiple human births.

HARVARD UNIVERSITY

SCIENTIFIC BOOKS

Some American Medical Botanists commemorated in our Botanical Nomenclature. By HOWARD A. KELLY. Troy, N. Y., The South-west Company. 1914. 8vo. 215 pp., 42 pl.

In this attractive and beautifully printed volume, which is at once a contribution to medical history and the history of botany, Professor Kelly has conceived the genial thought of giving some memorial records of American physician-botanists whose names have been commemorated in plants, some of which were discovered or first described by them. This eponymic practise was introduced by Linnæus, who, when he found some guest or disciple to be heartily interested in botany, would often dedicate a new genus or species to him. Before Linnæus, plants were called after the names of the saints, e. g., St. John's wort, St. Ignatius beans, etc.; and Pliny gives Eupatorium as the cognomen of Mithridates, King of Pontus, who discovered its virtues. Some of the eponyms formed from proper names were very inharmonious or barbarous, e. g., *Andrezejofskya*, *Eschscholtzia* (Chamisso), *Sirhookera* and *Peckifungus* (Kuntze). Some of these names were even misspelled, e. g., *Wisteria* for *Wistar*, but on the whole, what Kelly calls "amical floral nomenclature" was a pleasant practise, particularly in the eighteenth century, when friendly relations between European and American physicians were very close indeed. It is worth while to

list Dr. Kelly's remarkable series of botanist-physicians with the plants attached to their names. They are:

- Michel S. Sarrazin (1659-1734)—*Sarracenia purpurea* (Tournefort).
John Mitchell (1680-1768)—*Mitchella repens* (Linnaeus).
Cadwalader Colden (1688-1776)—*Coldenia procumbens* (Linnaeus).
John Clayton (1693-1773)—*Claytonia Virginica* (Gronovius).
John Bartram (1699-1777)—*Lantana Bartramii* (Baldwin).
Alexander Garden (1728-1792)—*Gardenia jasminoides* (Ellis).
Adam Kuhn (1741-1817)—*Kuhnia Eupatorioides* (Linnaeus).
Moses Marshall (1758-1813)—*Marshallia trincrva* (Schreber).
Caspar Wistar (1761-1818)—*Wistaria speciosa* (Nuttall).
Benjamin Smith Barton (1766-1815)—*Bartonia decapetala* (Muhlenburg).
David Hosack (1769-1835)—*Hosackia bicolor* (Douglas).
William Baldwin (1779-1819)—*Baldwinia uniflora* (Nuttall).
William Darlington (1782-1863)—*Darlingtonia Californica* (Torrey).
James Macbride (1784-1817)—*Macbridea pulchra* (Elliott).
Jacob Bigelow (1787-1879)—*Bigelowia Menziesii* (De Candolle).
Charles Wilkins Short (1794-1863)—*Shortia galacifolia* (Gray).
John Torrey (1796-1873)—*Torreya taxifolia* (Arnott).
Zina Pitcher (1797-1872)—*Carduus Pitcheri* (Torrey).
Charles Pickering (1805-1878)—*Pickeringia Montana* (Nuttall).
John Leonard Riddell (1807-1865)—*Riddellia tagetina* (Nuttall).
George Engelmann (1809-1884)—*Engelmannia pinnatifida* (Torrey).
Alvan Wentworth Chapman (1809-1899)—*Chapmannia Floridana* (Torrey & Gray).
Asa Gray (1810-1888)—*Lilium Grayii* (Hooker & Arnott).
Arthur Wellesley Saxe (1820-1891)—*Rumex Saxei* (Kellogg).
Charles Christopher Parry (1823-1890)—*Lilium Parryi* (Watson).

Elliot C. Howe (1828-1899)—*Stropharia Howeana* (Peck).

William Herbst (1833-1907)—*Sparassis Herbstii* (Peck).

George Edward Post (1838-1909)—*Postia Lanuginosa* (Boissier & Blanche).

Joseph Trimble Rothrock (1839-)—*Rothrockia cordifolia* (Gray).

Harry Hapeman (1858-)—*Sulivantia Hapemansii* (Coulter).

The biographies of all these worthies are presented in exhaustive and attractive style and will be a valuable source of reference to the future medical historian. Some of them, such as Adam Kuhn, B. S. Barton, Jacob Bigelow, George Engelmann and Asa Gray, are, of course, of great importance in the history of American botany. Alexander Garden, of the gardenia, or cape jessamine, was a prominent figure in the group of South Carolina physicians which Welch has pronounced to be the most important in the colonial period. The volume is extensively illustrated with rare portraits, facsimiles and beautiful photographs of the plants. To Dr. Kelly's friends it will always have a personal interest because he has put so much of his lovable self into it.

ARMY MEDICAL MUSEUM

The Deaf. Their Position in Society and the Provision for Their Education in the United States. By HARRY BEST. New York, Thomas Y. Crowell Co. 12mo. Pp. 340. Cloth.

There is, perhaps, no more accurate indication of the state of civilization reached by any people than the extent to which its handicapped classes are assisted to overcome their disadvantages and to approach a normal position in society. Judged by this standard, the people of the United States are rapidly advancing. Mr. Best has gathered a mass of very valuable data concerning a much-misunderstood class and embodied it in his book in a clear, intelligent and interesting arrangement.

It would be well if some way could be found to compel the reading of this book by every commissioner of education in the country, as

well as by others to whom the citizens have entrusted the shaping of educational procedure. The problem of the deaf has passed from the realm of charity to that of education, and the solution of it has become an integral part of the task of every public-school system. If the knowledge contained in Mr. Best's book could be assimilated by those in educational authority throughout the country, the deaf would be immensely benefited.

Like every other human activity that has not as yet been reduced to an exact science, the effort to enable the deaf to overcome their great handicap opens the way to many differences of opinion as to how it can be most efficiently accomplished.

Mr. Best endeavors to state the facts and let his readers arrive at their own opinions. But he very properly sums up his book in a few general conclusions.

He finds the matter of paramount importance to be the preventing of deafness, and that, up to the present time, this has received only minor attention, but is likely to receive a greater proportion hereafter because of the present general warfare against disease, and the campaign for eugenics. He points out that the two elements to be principally controlled are consanguineous and syphilitic marriages, as well as marriages between persons having deaf relatives, and second, the element of watchful supervision over the ears in connection with such diseases as scarlet fever, meningitis, measles, etc., since three fourths of the cases of adventitious deafness come as a secondary result of infectious diseases. Fifty-two per cent. of the cases of total deafness occur before the age of two years. If, through some agency like the "Child Bureau" of the national government, parents could be informed of the exceptional danger to the hearing during the first two years of life, they might be induced to secure more medical supervision of their children's ears, noses and throats during the early years. That, combined with increased intelligence concerning this matter on the part of physicians, would reduce the percentage of early deafness.

Second in importance to the prevention of

deafness comes the education of the deaf. Mr. Best calls attention to the extraordinary fact that in many states the laws for compulsory education do not apply to the deaf, whereas they ought to apply to them with greater force than to the hearing, as the deaf are in more extreme need of special training. He says that "in the wide sweep of education the deaf have been the gainers as no other people in the world have been." "Yet," he continues, "the victory of the deaf is not complete. So long as people look upon them as an unnatural portion of the race; as of peculiar temperament and habits . . . just so long will the deaf be strangers in the land in which they dwell." He goes on to say that "there is still more or less conflict as to methods (of instruction), but this does not seem vital to the success of the schools." In this opinion it would seem that Mr. Best is mistaken. The one thing that makes the deaf "strangers in the land in which they dwell" is the use of a foreign language, the language of the fingers and of gesture. This situation has been created by the "method" by which they have principally been educated. That the employment of these silent means of communication is not necessary is simply demonstrated by the fact that all the deaf children of Massachusetts have for many years been educated wholly by means of the common communication of the race without recourse to the foreign language of the hands, and that the largest school for the deaf in the world, the Pennsylvania Institution for the Deaf, is so conducted. If this can be done in Massachusetts and Pennsylvania, what state is willing to acknowledge that the intelligence of its citizens and the extent of its educational capacity is less than that of any other state? It would seem, therefore, that the *method* is vital to the success of the schools in gaining a complete victory.

Mr. Best finds that 18.2 per cent. of those born deaf can use speech as a means of communication. Are the other 82 per cent. of too low an order of intelligence to acquire this ability? Certainly not. They have not acquired it because they were not given the same chance fortunately enjoyed by the 18 per cent. who were taught by the proper methods.

At the opening of a chapter on "The Use of Signs as a Means of Communication," the author says: "Deaf children can not be educated as other children, and in the schools there have to be employed special means of instruction." So far as this "special means of instruction" refers to the use of a language of the hands in communication the statement is entirely false. Deaf children have been educated in large numbers without special means of communication, and it has been the error into which this writer has fallen that has been largely responsible for the isolation of great numbers of the deaf. This error was brought here by an unfortunate chance, from France, where it was long since abandoned. But, as the author points out, the trend of progress is plainly indicated to be away from the initial error of silent methods and toward the normal speech method.

There can be no objection to deaf adults using any form of communication between themselves that they desire or find convenient, and the ability to use the sign language and finger spelling can be acquired by any one in a very few weeks. But an ability to communicate with hearing people by means of speech and speech reading can not be acquired except through long and patient effort from childhood and should therefore be used exclusively during the educational period. As the use of the speech method becomes more universal the "differentiation from the rest of their kind," and the lack of absorption in the body politic to which the author refers will steadily decrease, since they will no longer be so largely "removed from the usual avenues of intercourse."

Mr. Best finds that though an early disappearance of deafness does not seem likely, it is apparently decreasing. His second chapter is entitled "The Deaf as a Permanent Element of the Population." His third chapter takes up the deaf with relation to the state; the attitude of the law and of legislation toward them. He finds that "legislation discriminatory to them has practically disappeared, and in judicial proceedings particular usage has almost entirely passed away."

Chapter four takes up the "economic con-

dition of the deaf." He states that "50 per cent. of the deaf over 20 years of age are reported in gainful occupations, the percentage for the general population being 50.3 per cent. In the five great occupations, agriculture, manufacture, service, trade and professions the proportions are about the same for the deaf and the general population. Their own achievements have thrown out of court the charge that they are a burden upon society."

THE WRIGHT ORAL SCHOOL,
NEW YORK CITY

Natural Sines to Every Second of Arc, and Eight Places of Decimals. By EMMA GIFFORD. Published by Mrs. Gifford, Oaklands, Chard, Somerset, 1914. Pp. vi + 543. Price £1.

It is evident to any one who takes the trouble to consider the matter that this is an era of efficiency in the computations of the laboratory and observatory as well as in the work of the great industrial plants of the world. The astronomer, the physicist, and he whom Sir George Greenhill often delights to refer to as the "mere mathematician" are all conscious that the time is past when the individual investigator should compute if he can get some instrument, human or mechanical, to do this work for him. And so we have in our day a remarkable surging forward of the flood of computing devices—slide rules of many types, listing machines, comptometers, cash registers which mechanically add, and all sorts of other devices which do for the computer what he one time was forced to do for himself at great expenditure of energy. And we also have, but in less marked degree, a number of new tables, ingenious little ones like those of Professor Huntington, and ponderous newly-computed ones like those on which M. Andoyer is still engaged. All these aids to computation are healthy signs that the scholar joins the "sharp-lined man of traffic" in seeking the greatest efficiency in his exhausting labors.

Of the recent tables for saving the time of the computer no one is more noteworthy than the one of natural sines which has been computed and recently published by Mrs. Gifford.

Georg Joachim computed such a table to ten figures and to every ten seconds, and this was published in 1596, after his death. This table was again printed in 1897, but was carried to only seven figures. Mrs. Gifford, however, has prepared a table extending one figure further than this, namely, to eight places, and has carried it to every second instead of every ten seconds. It is therefore apparent that here is by far the most complete table of natural sines that has ever been attempted. And not only is it the most complete but it is a model of convenience, so that the computer who has occasion to use a table of this kind will have good reason to thank Mrs. Gifford for her great care and patience.

It is hardly possible that such a table can be free from errors, particularly in cases where the last figure is near 5. Aside from this, however, a rather extensive use of the work by one computer for some months has revealed only a single error, namely, in $\sin 56' 40''$. Mrs. Gifford is correcting the tables in this and other minor respects, however, before issuing them.

The tables should have place in every college library and in every physical laboratory, observatory and mathematical workshop.

DAVID EUGENE SMITH

Principles of Physics. By WILLIS E. TOWER, CHARLES H. SMITH and CHARLES M. TURTON. P. Blakiston's Son & Company. 1914.

The teaching of high-school physics presents difficult problems. For each teacher there is undoubtedly a "best" text, and it is highly desirable that every teacher have a number of good texts from which to make the selection that seems, in practise, to be the best suited to himself. For this reason the text of Tower, Smith and Turton should be welcome. It does not claim to possess striking peculiarities, but rather to incorporate the best ideas found through extended experience of the authors.

The authors have attempted to adopt what they consider to be the conclusions reached by the "new movement in the teaching of physics." An introductory chapter is followed by one which is given to the explanation of a

selection of common things discussed under the title, "Molecular Forces and Motions." Here occur discussions of the diffusion of gases, the evaporation, diffusion and capillary action of liquids, crystallization, elasticity and general properties of matter. This introduction covers eight of the seventy-seven sections into which the book is divided, each section containing material enough for one recitation. The order of treatment of the subjects is as follows: Mechanics, Heat, Electricity, Sound, Light. By summarizing at the close of each section the important topics treated therein, and by setting problems which are related to the life of the pupil as well as to the principles of physics, the authors have made a special effort to produce a helpful book. Mathematical expressions are not avoided, but are used only where they are of apparent advantage to the student; indeed this advantage should be the only justification for mathematical expressions in either elementary or advanced physics. The illustrations, in both number and selection, are to be commended. The volume is distinctly a text-book, all of which is to be taught in the year's course in physics, save perhaps some of the numerous exercises which are found at the close of each lesson. The value of the work can only be ascertained by experience in the class room, but the spirit of the authors and their apparent success in applying it in the preparation of this book must commend the text to the consideration of every high-school teacher.

G. W. STEWART

SPECIAL ARTICLES

ANTAGONISM AND BALANCED SOLUTIONS¹

THE term *antagonism* came into general physiology from medicine, where it was used in the seventies by Rossbach, Luchsinger and others to designate the opposing types of physiological action produced by certain chemical substances. Luchsinger, Langley, Sydney Ringer and others applied the term to that type of physiological situation seen in the opposite effects produced by atropine and pilo-

carpine on the sweat glands. One alkaloid, atropine, stimulated the activity of the gland, the other depressed it, and one effect could be made to partly or wholly supersede the other by the proper adjustment of the concentration and quantity of alkaloidal solutions used. It was found possible to establish physiologically equivalent quantities of each alkaloid which would exactly nullify the action of the other when applied to the tissue, and a given physiological result could be calculated from given quantities of the antagonistic substances. As Luchsinger saw it, the action of these substances was like algebraic *plus* and *minus* and came back to mass action (*Massenwirkung*) and affinity, a view accepted in effect by Langley and Ringer. In these experiments physiological antagonism meant opposing action on a definite function as a criterion. Contraction of the frog's heart, action of the salivary gland and contraction of the pupil of the eye were examples of such criteria.

In work of this type the antagonists were used in simple solutions applied serially to the tissues in question, and the fact of antagonistic action was demonstrated by the disappearance of the action characteristic of the first substance upon the application of the second substance. The simultaneous application of the antagonistic substances seems not to have been made.

Work of this type developed a number of important differences in the behavior of supposed antagonists. Luchsinger found when the activity of the sweat gland of the cat was used as a criterion that pilocarpine and atropine produced opposite actions and that each was able to efface the other as wave-hollow effaces wave-crest or as algebraic plus effaces algebraic minus. This ability of each to efface the other and to produce the opposite physiological state in either order of application Langley proposed to call mutual antagonism.

This clean-cut, two-way, type of result, however, was not the rule, and for two chief reasons. (1) It was unusual that the action of two substances should cover precisely the same area of function and thus fully oppose each other throughout their effects. As a result,

¹ Published by permission of the Secretary of Agriculture.

one was likely to cause changes in some structure not affected by the antagonist, hence side effects turned up to confuse the issue. This trouble was due to the fact that more than one function was affected and the criterion had thus become complex. (2) A second difficulty arose from differences in the point to which a given action was referred. For example, Luchsinger found that pilocarpine stimulated the activity of the sweat gland of the cat to a point *above* normal activity, while atropine brought it *below* the normal rate. In carefully adjusted doses of physiological equivalents, the resultant action was a normal rate. Here the point of reference was the normal rate of activity and activities could be counted as plus or minus. When, however, Ringer tested the action of atropine and muscarine on the beat of the isolated frog's heart another type of situation developed. When the heart was treated with muscarine the beat sank to zero or near it. When it was treated with atropine depression also resulted, but only to such a degree as to clearly slow the beat. Both were thus depressants, although in unlike degree. When a "muscarine" heart was treated with atropine it was apparently stimulated, since the beat rose to the rate characteristic of atropine, but, with reference to the normal beat, it still remained depressed. When an "atropine" heart was treated with muscarine no change of beat was seen, muscarine being clearly not able to antagonize atropine. Here two substances acting alike as depressants are called antagonists not because one can raise the action above normal or even to it after depression by the other, but because one is able to efface the other and bring up the action to its own characteristic rate. Here the antagonists are both minus quantities with reference to normality and the result is the lesser minus quantity. Ringer called this a case of antagonism; it was not, however, mutual antagonism, since only one was able to replace the other and no opposite physiological state was produced. These two instances are clearly different in important particulars.

A little later, Ringer, working with small organisms placed in salt solutions, introduced still another phase of the problem. The quan-

titative plus and minus action, seen when the effect exerted on the single function was taken as the criterion, following successive applications of the chemical substances, was replaced by the action produced by a mixture of ions acting on the total organism. Here the effect of substances in simple solutions on the survival time gave the pure effect of each substance. The antagonistic action could not be tested as heretofore by successive exposures to the substances concerned, since death was the point sought in the experiment. Consequently a change of method was introduced by testing the organisms in mixtures of different proportions. A new sort of result appeared also. With a definite function as a criterion, antagonists merely offset each other more or less completely, the range of results being above or below the normal mark according to the magnitude of the stimulating action of one or both of the antagonists. No resultant action seen was more favorable than that of the more stimulating antagonist. A new feature, therefore, appeared when Ringer found that organisms sometimes lived longer in mixtures of salts than in the most favorable of the components. The term antagonism was again extended by Ringer to cover this third type of situation.

The introduction of life or death, the survival time, as the criterion, complicated the problem in at least one important way. Since in a more or less orderly manner, death means that one or more functions break down or cease to correlate. Hence a disturbing influence introduced by a given ion may harm one function and bring about death, another ion may affect an entirely different function and in a quite different way bring about the same visible response. Hence several ions may all be operating in a cell entirely independently of each other as regards function, and bring about an unvarying response. Death is the uniform result following from a variety of types of injury in the organism. Here, all idea of antagonism, as originally defined, may be absent, owing to the possibility that ions may not meet each other in physiological opposition in any one function. With death as the criterion it seems that one is hardly justified in asserting

antagonism unless it can be shown that somewhere in the complex of reactions one or more functions have been oppositely affected by the supposed antagonists. Death gives an unanalyzed result in which antagonisms may or may not have played a part.

The ideal criterion would be a single clear-cut function that by acceleration or by retardation in its activity would give information concerning the way in which definite external factors affect it. It is difficult, perhaps impossible, to carry the physiological analysis thus far, but the use of any one function that gives results capable of quantitative expression simplifies the problem and approaches more closely to certainty that antagonisms do exist. It is not to be understood that the survival time (death criterion) can not indicate antagonism in a rough way, but only that it does not necessarily indicate it.

What, then, is antagonism? In general, the historically established sense in which it came into general usage among physiologists should be retained as long as it clearly covers the idea with which it was associated. As new conceptions enter they should be designated in fitting terms, in order that confusion may be avoided. In the original sense in medicine, antagonists were much the same as antidotes, antagonists being sought for poisonous substances. Here clearly the idea of the physiological effacement of one by the other was generally accepted. Oftentimes a restoration to the normal was a result of such effacement, but such was not necessarily the case in order to have antagonism. Sometimes, each of the antagonists could efface the other and produce the opposite physiological state, illustrating mutual antagonism, but more frequently one antagonist only was able to efface the other, illustrating simple antagonism. The work developing these results was based on the serial application of the solutions to the organ. We are now confronted with the fact that, in mixtures of salts, the growth rate, survival time, or quantity of ions absorbed, as possible criteria, is found to exceed that observed in the sum of the actions of the constituents in unmixed solutions.

If we recur to Luchsinger's conception of

algebraic plus and minus we interpret the frequently observed increment above the expected result not only as indicative of the physiological effacement of one constituent by the other, but as indicative also of an effect beyond simple physiological opposition. It is antagonism in the historic sense of animal physiology plus something else. By Osterhout this increment over the results to be expected on the basis of the effacement of the effect of one antagonist by that of the other, the "something else," is proposed as a *measure of antagonism*. It seems to the writer that this effect comes not from the physiological opposition of the constituents, but rather from their cooperation in the cell in affecting favorably the total balance of cell activities. It is hard to see in this favorable action merely an expression of physiological opposition; it appears much nearer to the "synergism" of the older physiologists, a term used to designate physiological cooperation as opposed to antagonism.

In our present uninstructed condition concerning the activities at play in the living cell, it is hard to see how any scheme can at this time be proposed by which we can designate the degree in which ions entering the plant come into physiological opposition in the manifold functions likely to be affected by them. The result obtained by the investigator is the resultant of an indefinite number of interactions on few or many functions, and we can not assess its separate antagonisms and "synergisms." We are only able to say whether this result is above or below that obtained in the control medium. This control medium may furnish merely a fixed point for comparison or it may in addition also furnish an expression of normality.

In sea water we have the interesting case of a balanced solution, a mixture of salts, each by itself toxic in the concentration present in the natural medium, but in the mixture seen in the sea water, not only capable of sustaining life, but of nourishing marine organisms in so far as the ash constituents go. It is evident, since the individual constituents cause death under circumstances hardly explicable on the basis of nutritional failure, that we have here a group of antagonisms and synergisms so

operating that all functions are sustained in effective cooperation. Not only do the different salts mutually offset each other's physiological deficiencies, but they are able to offset the usually harmful action of the solvent. Loeb has found an interesting experimental subject in *Fundulus*, a fish which is at home not only in the complete mixture, but which likewise survives for a time in distilled water. In the case of organisms which survive indefinitely in distilled water, it is likely that many do so largely by virtue of the salts contained in their own bodies. In general it appears that pure water extracts ions more or less rapidly from many plants and animals, and in case the experimental organism in question is of considerable size and the volume of water sufficiently limited the medium may easily get enough ions from the experimental plant or animal to offset the harmful action of the pure water. The ability of *Fundulus heteroclitus* to part with considerable quantities of salts to fresh water without immediately evident injury has been shown by Sumner. This fish is, however, hardly typical of marine organisms as a whole. In the red algae, incomplete mixtures are injurious, as in *Fundulus*, but, unlike it, they are promptly killed by distilled water, which for them must be listed with the other constituents which, taken individually, act as fatal poisons. In this case, the mixture of salts is required to antagonize or efface the action of the water. A harmful action has been shown to characterize distilled water when used as a medium for various land plants as well, and to antagonize or efface this harmful action certain mixtures of salts, strikingly reminiscent of sea water in many important points, the so-called nutrient solutions, were long since devised by Knop, Sachs and others. It has been shown more recently by Osterhout and others that the so-called nutrient salts are toxic to land plants when taken individually in much greater dilution than has been generally supposed.

In both sea water and the more or less dilute nutrient solutions present in the soil, normal life is sustained as a rule only in mixtures of proper proportions and necessary concentration. Since salts are required in both cases

to overcome the harmful action of pure water, as well as that of the salts themselves, there seems to be no reason to seek to limit the use of the term "balanced solutions" in the manner suggested by Loeb and Osterhout. Unless we admit that malnutrition due to a deficiency in nutrient salts is a form of toxicity excited by the substances present, we can hardly escape the alternative proposition that the missing salts are injurious *in absentia*.

RODNEY H. TRUE

BUREAU OF PLANT INDUSTRY,
U. S. DEPT. OF AGRICULTURE

ON THE OSMOTIC PRESSURE OF THE JUICES OF DESERT PLANTS

In 1907 Drabble and Drabble¹ argued from a series of plasmolyzations of the leaf cells of a number of British plants from a range of habitats that physiological dryness of the substratum is the primary factor in the determination of the osmotic strength of the contents of the leaf cells of flowering plants. About four years later Fitting² applied the plasmolytic method in an extensive reconnaissance physiological study of the vegetation of the rocky peaks and slopes of the Chaine de Sfa and the adjacent lowlands, comprising concentrated salt marsh and arable oasis. Here he reports some enormously high concentrations of cell sap, such indeed as would theoretically give pressures of over 100 atmospheres if confined in suitable semipermeable membranes surrounded by pure water.

The results of these two papers force upon one the conviction that observations of the concentration of the cell sap may form a legitimate, and indeed essential, feature of comprehensive and thoroughgoing ecological or phytogeographical study.

One must note, however, that the number of observations from each habitat studied by Drabble and Drabble was small, and that their maximum intensity of dryness was not very great. Again, there is no satisfactory series of determinations of the osmotic pressure of the sap of mesophytic plants to serve as a

¹ Drabble and Drabble, *Bio.-Chem. Jour.*, 2: 1907.

² Fitting, *Zeitschr. f. Bot.*, 8: 1911.

basis of comparison for Fitting's xerophytic series. Furthermore, both investigations were carried out by the use of plasmolytic methods, the accuracy of which when used under any but the most ideal conditions is open to some doubt.

Finally, the possibility of the existence

zona, during February, March and April, 1914. As a basis of comparison determinations on species of the spring and early summer native and naturalized flora of the vicinity of the Station for Experimental Evolution were made.³ Each series comprised not far from two hundred determinations based on a

Draughtsman's curves smoothing the summed percentage frequencies of osmotic pressures of various magnitudes in the sap of plants of the deserts around Tucson and from the various habitats near Cold Spring Harbor, Long Island.

within the living plant tissues of concentrations so high as these reported by Fitting has been questioned by plant physiologists.

It has therefore seemed to us highly desirable that further series of evidence should be gathered. Such data to be of real value should comprise extensive series of as nearly as possible comparable determinations from desert and moist regions. The technique which seemed to us the most trustworthy is the well-known freezing-point lowering method.

The director of the department of botanical research of the Carnegie Institution of Washington made it possible for two of us to carry out a series of cryoscopic determinations on the spring flora of the vicinity of Tucson, Ari-

zona, during February, March and April, 1914. As a basis of comparison determinations on species of the spring and early summer native and naturalized flora of the vicinity of the Station for Experimental Evolution were made.³ Each series comprised not far from two hundred determinations based on a

large number of representative species. Oacti are excluded from the comparison because of known peculiarities. The results will ultimately be published in detail. Preliminarily the differences between the two regions are most convincingly brought out by the accompanying diagrams. In these the actual frequencies of osmotic pressures⁴ of various magnitudes have been

³ The methods used were those already described (see Gortner and Harris, *Plant World*, 17: 1914), except for the fact that the freezing-point lowerings were determined by vaporization of ether in a Dewar vacuum tube jacket surrounding the freezing tube in which the bulb of the Beckmann thermometer was inserted.

⁴ These are obtained directly from the depressions of the freezing point, corrected for super-

reduced to a percentage basis and these relative frequencies summed from the beginning for each successive grade. The curves are merely draughtsman's curves smoothing the empirical frequencies, but for present purposes they are quite good enough.

From such curves one may read off at once the relative frequencies of pressures of different grades. Thus for the Cold Spring Harbor series fifty per cent. of the pressures are about 10.5 atmospheres or lower, whereas in the Desert series fifty per cent. of the pressures are 15.7 atmospheres or higher. In the Tucson series about thirty per cent. of the concentrations are the equivalent of over 20 atmospheres, whereas in the Cold Spring Harbor series only about three per cent. of the cases exceed this value.

Note also that in the Desert there is a higher maximum and a higher minimum than in the more mesophytic habitat. The range of variation is also far greater in the Tucson than in the Cold Spring Harbor series.

In using cryoscopic methods we have so far failed to find pressures so high as those recorded by Fitting. We are not, however, ready to suggest that they do not occur. Possibly our failure to demonstrate them in the Tucson region may be due to the fact that our determinations were carried out at the close of the winter and spring rainy season, and hence on plants which had not been subjected to the maximum dryness of the region in question during the growing season of the year in which the determinations were made.

J. ARTHUR HARRIS,
JOHN V. LAWRENCE,
ROSS AITKEN GORTNER

ON THE GENUS TRACHODON¹

In 1902 Mr. J. B. Hatcher published an article² entitled "The Genera and Species of cooling, by the use of tables already published. See Harris and Gortner, *Amer. Jour. Bot.*, 1: 1914.

¹Published with the permission of the Director of the U. S. Geological Survey.

²*Annals of the Carnegie Museum*, Vol. I., 1902, pp. 377-386.

the Trachodontidae (Hadrosauridae, *Claosau-ridae*) Marsh," in which the conclusion was reached

that the ten genera [of the Trachodontidae] which have been proposed should be reduced to two. *Trachodon* Leidy and *Claosaurus* Marsh, while the remaining eight genera should be treated as synonyms of *Trachodon*, which should also be made to include *T. (Claosaurus) annectens* Marsh; while the smaller *Claosaurus agilis* described by Marsh from the Kansas chalks [Niobrara] may still be considered as pertaining to a distinct genus."

These conclusions were almost unanimously adopted by American vertebrate paleontologists in their subsequent work, and this general use of the term *Trachodon* has continued up to the present time.

The finding of more perfect material in recent years has shown that several of the species formerly referred to *Trachodon* represent distinct genera, and in the light of these discoveries Hatcher's reduction now appears to have been too radical, but he was probably correct in restricting *Claosaurus* to the single species from the Niobrara formation.

It is unfortunate, however, that this view of the genus *Trachodon*, which includes species from the Judith River formation to the close of the Lance, has become so widely accepted by paleontologists.

In the first place the type of the genus (*Trachodon mirabilis* Leidy) is from the Judith River formation and was founded upon inadequate material consisting of "specimens of teeth generally very much worn and in a fragmentary condition," so that it is quite impossible to identify positively with them better and subsequently discovered specimens.

That later Hatcher³ appreciated this fact is clearly shown by the following extract:

Although the trachodonts are easily distinguishable by their teeth from the other Dinosauria of these beds [Judith River] it is scarcely possible to identify the various species of this genus or the genera of the family from the teeth alone.

Even though it eventually be found that

³T. W. Stanton and J. B. Hatcher, "Geology and Paleontology of the Judith River Beds," Bull. 257, U. S. Geol. Surv., 1905, pp. 96-97.

Trachodon can be placed on a sound footing, there is now reason for believing this genus is not present in the Lance formation, as indicated by the fewer number of teeth in all of the known specimens from the Judith River, Belly River and Two Medicine formations.

In the U. S. National Museum collections there are several complete dentaries of the Lance trachodonts in which the vertical rows of teeth vary from 52 to 57 in number. All of those in the collection from the other formations mentioned above have fewer rows, varying from 39 to 47. When it is known that each vertical row has from six to ten teeth, the difference in the total number is considerable.

The same condition prevails in the few maxillae available. It thus seems that the earliest known trachodonts as in the more primitive Ceratopsians, have a smaller number of teeth, so that now it may be safely asserted that one of the marked phases in the specialization of the members of this group in successive geological periods is a progressive increase in the number of teeth in the dental magazines.

Since it is now known that the genus *Trachodon* is based upon specimens from the Judith River formation, and that all available trachodont material from that and equivalent formations shows a reduced dentition, this smaller number of teeth would in itself constitute a difference sufficient to restrict the genus *Trachodon* to species from the Judith River formation.

This difference I have no doubt will be augmented by other characters when sufficient material is obtained for comparison. I would therefore restrict the genus *Trachodon* to Judith River species.

This leaves the Lance trachodonts without generic designation, and it will on that account be necessary to revive one of the older generic terms, but I find that had been done before the appearance of Hatcher's article. In 1901⁴ Lucas called attention to the identity of the type of *Thespesius occidentalis* Leidy with the homologous parts of *Claosaurus*

⁴F. A. Lucas, "Paleontological Notes," SCIENCE (2), Vol. 12, 1900, p. 809.

annectens Marsh, and "that consequently this Dinosaur must be known by Leidy's name."

In 1902⁵ Hay, upon the authority of Lucas, made *Claosaurus annectens* a synonym of *Thespesius occidentalis*, including under the same genus the Niobrara species *C. agilis*, but this proposed change in nomenclature has been entirely ignored by paleontologists in subsequent work.

I have recently compared the types of *Thespesius occidentalis* Leidy and *Claosaurus annectens* Marsh and can testify to the close similarity of the homologous bones. The inadequacy of the type material upon which *Thespesius* is based (two caudal centra and a proximal phalanx) is fully recognized, but that these pertain to a trachodont dinosaur there can be no doubt. It is now positively known from the geological mapping done in recent years, in the locality where this material was obtained, that the specimens came from the Lance formation on the Grand River in what is now the state of South Dakota. Despite the meagerness of the material upon which it is founded, it seems to me that *Thespesius*, being the older term, is the logical choice of names for the designation of the trachodont dinosaurs from the Lance formation.

While it can not be positively demonstrated that *occidentalis* and *annectens* are identical, it is equally true that they can not be shown to represent distinct species. Since the localities from which the type specimens came are not far apart geographically, it appears most probable, however, that they do represent one and the same species. I would therefore endorse the use of *Thespesius occidentalis* as first proposed by Lucas.

The chief points that I have attempted to bring out in the preceding lines may be summed up as follows:

1. That the trachodont dinosaurs of the Judith River and equivalent formations have fewer vertical rows of teeth in the jaws than those from the Lance.

2. That this feature constitutes a sufficient

⁵O. P. Hay, "Bibliography and Catalogue of the Fossil Vertebrates of North America," Bull. No. 179, U. S. Geol. Surv., 1901, pp. 502-603.

structural difference to separate generically all Judith River, Belly River and Two Medicine trachodonts from those obtained in the Lance formation, and that therefore the use of the term *Trachodon* should be restricted in its application to some one of those trachodonts found in the older beds.

3. That the restriction of the genus *Claosaurus* to the Niobrara species *C. agilis* Marsh first proposed by Hatcher be endorsed.

4. That *Claosaurus annectens* Marsh should be regarded as a synonym of *Thespesius occidentalis* Leidy as first proposed by Lucas.

THE SOCIETY OF AMERICAN BACTERIOLOGISTS. II

Technique

Under the supervision of G. F. Ruediger

The Bacteriological Work of the Bureau of Chemistry and Its Possibilities: CHARLES THOM.

The papers presented by members of the bacteriological staff of the Bureau of Chemistry are fairly representative of the manner in which numerous problems arising from the enforcement of the Food and Drugs Act are being met by the bacteriological laboratory. Very many of the food products and other preparations met with in inspection work have not been adequately studied by bacteriologists. No analysis of the flora present in such substances is available. Standard methods for testing them have not been developed. The workers into whose hands they fall must then make a full study of several to many brands of the commercial article and very frequently follow the product every step of the way back to the actual producer before adequate data can be obtained to determine what action, if any, shall be taken by the bureau. The members of the Bacteriological Society are earnestly requested to aid this work whenever opportunity arises by studying the bacteriological conditions obtaining in food-stuffs and the standardization and publication of methods of procedure.

In addition to its inspection work, the bureau is now establishing a research laboratory to take up food deterioration, fermentation and technically bacteriological and mycological work upon unsolved problems concerning foods and drugs. This work will be carried in the closest possible

cooperation with the chemical laboratories of the bureau dealing with the same related problems. By these two methods of attack it is hoped to enlarge our knowledge of the flora of food stuffs and the relation of these organisms to normal and abnormal conditions as found.

Methods of Counting Bacteria: ROBERT S. BRIDG.

Three methods of counting the number of bacteria present in various substances have been generally recognized. In order of their historical development, they are the microscopical method, the dilution method and the plating method. For the past few years, however, the latter method has been used, especially among American bacteriologists, almost to the exclusion of the others and this, in spite of the fact that what little comparative work has been done indicates that certain uncontrollable elements in this technique cause large errors.

Among other causes of irregularities in the counts, there are two which tend to lower the count in both the dilution and the plating method. One of these is the fact that the organisms present in the substance under examination may fail to grow in the culture medium used, and the other, that the clumping of the organisms reduces the number of centers from which growth occurs. The microscopical technique is free from these objections, but it is open to another in all cases where a count of living organisms only is desired. This objection arises because of the fact that it is ordinarily impossible to distinguish organisms which were alive at the time the preparation was made from those which were dead. This difficulty causes the count obtained in this way to be higher than it should be.

These conditions which have thus far proved to be uncontrollable in all of the three methods are largely responsible for the big discrepancies in the comparative counts which have been made. These discrepancies show most strikingly that all so-called bacterial counts are much better styled "estimates" than "counts." Statements that certain substances, such as milk, water, sewage and the like, contain such and such numbers of bacteria are particularly unfortunate, for they are plain misstatements of facts. In most cases the figures given represent counts of colonies on agar or gelatin and may be properly so recorded but these figures are usually far below the actual number of bacteria present.

So far as raw milk is concerned, microscopical methods of counting have been shown to have great usefulness, for, in these cases, the number of

dead bacteria present is at a minimum. Moreover, in those cases where they are present, they are just as indicative of the past history of the milk as are living bacteria. Very variable conditions in regard to the clumping of bacteria in milk have been observed. In many cases the bacteria occur largely as single individuals or as clumps of twos, in other cases the milk is filled with compact clumps which could not be separated by any known methods of plating. Where thick cream is present and the right types of bacteria occur, colonies may be formed much like those found on agar or gelatin. These variations in clumping produce very variable effects on the plate count which would be unrecognizable where this technique is used alone.

The Standard Method of Determining Nitrate Reduction: ROBERT S. BREED.

Attention is drawn to the fact, more or less generally known, that the Committee on Standard Methods of Bacterial Water Analysis have inadvertently given us two different formulae for nitrate broth in each of the two editions of the Standard Methods which have been published. All of the formulae call for one gram of peptone per liter, but the amount of nitrate varies. Altogether three different amounts are mentioned, namely, 2 grams, 0.2 gram and 0.02 gram per liter.

The committee's statement that the nitrate reduction test is sometimes quite erratic has been explained for some cases at least by tests which have been carried out at the New York State Experiment Station. Fifty cultures of bacilli of the colon group, isolated from a sewage-polluted stream, gave very erratic results with the standard broth which contained 0.2 gram of nitrate per liter, scarcely one third of the cultures giving results which showed a clear reduction. However, as soon as the amount of peptone was increased to five grams per liter, all of the cultures gave positive reactions for all tests.

On the other hand, tests for thirty cultures of bacilli of the *subtilis* group isolated from soil gave unmistakably positive or unmistakably negative results in a number of tests in the same nitrate broth. Varying the amount of peptone from one to five grams per liter had no influence on the results. Twenty of these cultures reduced nitrates, while ten failed to do so. In all cases there was a vigorous growth of the bacilli in every tube.

Tests with a single culture of an unknown soil organism showed, however, that it was necessary to be cautious in recommending that the amount of peptone in the standard broth be increased. This

organism showed a condition the exact reverse of that just reported for the colon bacillus. Positive results were obtained in all cases where 1 gram of peptone per liter was used, while increasing the amount of peptone caused erratic and finally negative results when as much as 5 grams per liter was used.

Evidently nitrate reduction should be tested in a broth in which the organism to be tested will grow vigorously. Irregular results are open to suspicion in all cases. No one broth can be used for all organisms and suitable broths must be devised to fit each group of organisms. It is particularly unfortunate to report an organism as lacking the power to reduce nitrates when it fails to reduce them in a broth in which it does not grow. Either such results should not be reported at all or reported as doubtful.

Starch Agar, a New Culture Medium for the Gonococcus: EDWARD B. VEDDER.

Starch agar is a beef-infusion agar (1.5 per cent.) without salt or peptone, to which is added 1.0 per cent. of starch, preferably corn-starch, though potato starch or tapioca will serve. Reaction, 0.2-0.5 acid to phenolphthalein. The advantages of this medium are as follows:

1. The gonococcus grows very freely on this medium, producing a heavy growth suitable for the preparation of vaccines or antigens.
2. When the tubes are sealed with paraffine, cultures remain alive upon this medium for a long time, at least 20 days, so that transfers of stock cultures may be safely made every two weeks instead of every three or four days, as is customary when other media are used.
3. This medium may be melted and used in pour plates in order to isolate gonococci in pure culture from gonorrheal pus.
4. Some other organisms that are usually cultivated with considerable difficulty grow well on this medium; i. e., certain strains of tubercle bacilli, the lepra bacillus (Duval), and freshly isolated streptococci and pneumococci.
5. The medium is suitable for routine use as practically all organisms grow as well or better on this medium as on plain agar.

The great simplicity of preparation of this medium and its many advantages appear to indicate that it may be very useful to many workers.

A New and Rapid Method for the Isolation and Cultivation of Tubercle Bacilli Directly from the Sputum and Feces, with the Aid of Sodium Hydrate and Gentian Violet-egg-meat Juice Media: S. A. PETROFF.

The object of this investigation was to devise a simple, practical and reliable method for the isolation and cultivation of the tubercle bacillus from the sputum and feces. Most of the methods employed in the last twenty years do not give uniformly positive results.

Taking into consideration the inhibitory action of gentian violet on many organisms, it was selected as the most favorable stain.

Preparation of the Media

I. *Meat Juice*.—Five hundred grams of beef or veal are infused in 500 c.c. of a 15-per-cent. solution of glycerine in water. Twenty-four hours later the meat is squeezed in a sterile meat press and collected in a sterile beaker.

II. *Eggs*.—Sterilize the shells of the eggs by immersing for ten minutes in 70 per cent. alcohol. Break the eggs into a sterile beaker, mix well and filter through sterile gauze. Add one part by volume of meat juice.

III. *Gentian Violet*.—Add sufficient 1 per cent. alcoholic gentian violet to make a dilution of 1 to 10,000.

Place in sterile test tubes and inspissate for three successive days. First day at 85° C. until all the medium is solidified. On the second and third days not more than one hour at 75° C.

Method of Isolating Tubercle Bacilli from Sputum

The use of fresh sputum is advisable. A mixture of the sputum and a 3-per-cent. sodium hydrate solution are left in the incubator for 20–30 minutes, then neutralized to sterile litmus paper with normal hydrochloric acid, centrifugized and the sediment inoculated into the tubed media.

Method of Isolating Tubercle Bacilli from the Feces

The isolation of tubercle bacilli from the feces is not an easy problem. The concentration of the sodium hydrate is not as important as the length of exposure. The solid food particles are removed from the feces by dilution with water and filtration through gauze.

The filtrate is saturated with sodium chloride and at the end of half an hour all the bacteria will be found floating in a fine film. This film is collected and normal sodium hydrate added, shaken well and incubated at 37° C. for 3 hours. Then neutralized as is sputum, centrifugized and sediment inoculated.

The method presented has proven very simple and accurate for the isolation of tubercle bacilli from the sputum. The partial success in isolating and cultivating tubercle bacilli from the feces may

be due to the fact that many of the bacilli are possibly dead.

Comparative Analysis of Several Peptones: R. C. COLWELL.

An investigation of the comparative merits of four brands of peptone is being made to determine the advisability of substituting an American brand for Witte's in Standard Methods of Bacteriological Analysis. The following table embodies the results of the chemical analysis.

	Total Nitrogen %	Ash %	Moisture %	Fermentation of Peptone Broth	Presence of Sugar	Acidity of 1 % Peptone Broth
Witte's "Peptonum Siccum"	14.92	2.09	4.97	0	0	0.40
Digestive Ferments Co. "Peptone Powder Bacteriological"	15.83	4.18	2.96	0	0	0.24
Armour & Co. "Peptone Powdered containing 10% lactose"	13.67	5.76	4.09	+	+	0.60
Bausch & Lomb "Peptone from meat, dry"	12.82	4.32	6.06	+	+	0.56

The tests made upon the peptones to determine their relative reliability in the making of culture media has not yet covered long enough time to warrant any definite conclusions. However, it may be said that those peptones containing lactose seem to be inferior to those which are free from lactose.

A New Method of Precipitating Cellulose for Cellulose Agar: F. M. SCALZ.

The method of precipitating cellulose to be used for the preparation of cellulose agar is as follows: 100 c.c. of concentrated sulphuric acid are diluted with 60 c.c. of distilled water in a two-liter Erlenmeyer flask. The diluted acid should be cooled to about 60° to 65° C. Moisten with water five grams of filter paper, which are sufficient for one liter of cellulose agar, and add it to the acid, which should be vigorously agitated until the cellulose is dissolved. The flask is then filled as quickly as possible with cold tap water. The process of dissolving the paper and filling the flask requires about one minute. The precipitate may now be thrown on a filter and washed with distilled

+ Lactose, about 10 per cent.

water until the filtrate no longer gives a test for sulphuric acid. As the volume of the suspension finally drains down to about 200 c.c. any deposit of cellulose on the filter may be removed with a camel's-hair brush. A hole is then punched in the bottom of the filter and the whole precipitate washed out and made up to 500 c.c., when it may be added to 500 c.c. of 1-per-cent. agar containing the nutrient salts. Cellulose-destroying bacteria were plated on a medium containing cellulose precipitated by this method and on one containing cellulose from Schweitzer solution. The destruction of the cellulose was about the same in both media.

New Technique for Studying Halophytic Organisms: K. F. KELLERMAN AND N. R. SMITH.

1. For staining flagella from salt media the bacteria are placed in a salt water suspension, killed by addition of 10 per cent. formalin, then placed in collodion dialyzing tubes and the soluble salts removed by dialysis. The bacteria are thrown down by centrifuging, and the residue spread on clean slides and stained by any method desired.

2. For isolating bacteria injured by heating to 42° C., use silica jelly. This can not be mixed with beef broth or peptone. When these nutrients are desired, pour sterile Petri plates of beef agar or peptone agar, allow them to harden for twenty-four hours, then for the isolating medium use synthetic salt solution and silicic acid solution, and pour this rapidly over the sterile beef or peptone agar plates and allow to remain perfectly quiet. The silica jelly forms a layer over the agar layer and the nutrients mix by diffusion.

3. Use collodion sacs to maintain constant supply of slightly soluble salts in clear solutions in bacterial culture flasks.

The Relative Merits of the Bubbling Method of Enumerating Air Bacteria: JOHN J. WENNER.

The writer is making a study of the modified Petri sand filter and the Rettger aeroscope bubbling filter for the purpose of determining their relative degree of efficiency, simplicity and practical value. The sand filter was, at first, set up as described in a previous paper by Weinzirl and Thomas ('12). As this apparatus was very cumbersome, it was soon modified by discarding one stopper entirely, holding the sand in the tube by means of a tight wire gauze, and attaching the aspirating tube directly to the main filtering tube. The great weakness of the sand filter is in the transference of the organisms caught in the sand, to the plate, so as to be easily and accurately counted. This was done in three ways: (1) The

sand was distributed among several sterile plates and gelatin added. (2) The sand was transferred to a small sterile flask holding 10 c.c. of salt solution and an aliquot part plated. (3) The sand was transferred to a sterile test-tube holding 5 c.c. of salt solution, thoroughly washed, and the liquid plated with an equal amount of strong gelatin. This last method appears to be the most practical.

The Rettger aeroscope was used as originally described by Rettger ('10). A second plate, from washing the aeroscope and test-tube, should, in all cases, be poured.

The two filters were run simultaneously and consecutively under similar conditions. Air was taken in a dusty attic room and from a specially prepared box.

Both methods are equally simple and both filter with a high degree of accuracy. In plate pouring the aeroscope is simpler and contamination is not so easy. Besides the bubbling method is visible and audible, which may at times be very desirable. The writer's work has not been completed, but from his results thus far obtained the bubbling method gives him an excess in the number of colonies, over the sand filter. As technique is very delicate, a large number of tests have to be made for the results to be of any value.

One of the great drawbacks in the practical use of the air filter is the inconvenience of the aspirator. We need an aspirator that is easily transferred from place to place, one that is simple and yet will give a fair degree of accuracy, as well as a uniform and continuous rate of flow. For this purpose the writer has been experimenting by placing two movable tanks in a wooden box. The tanks are connected with a rubber tube while another tube from each tank extends to the outside. The filter is attached to the proper tube and the water passed from one tank to the other.

Suggestions for Partial Anaerobic Cultures: WARD GILTNER.

Anaerobiosis and aerobiosis are relative terms. The oxygen requirements and tolerance of micro-organisms present a gradation from practically an absence of oxygen pressure to many times atmospheric pressure. The lowering of oxygen tension by biological means, Nowak's *B. subtilis* cultures, was introduced in connection with the growth of *Bact. abortus*, an organism requiring a slightly lower oxygen pressure than atmospheric. In this method the oxygen-consuming culture and *Bact. abortus* are usually grown in vitro separately, the two cultures being placed in a Novy or similar sealed jar. A simpler method is desirable. Re-

cently Geo. D. Horton⁵ has proposed to grow both organisms on adjacent agar slants separated by a glass slide in the same test tube.

We suggest the following special tubes in which the culture surfaces may be kept separate while the air chamber is continuous or freely communicating between the sides. U tube with perforated corks and U capillary tube U and H tube. Probably the H tube will prove the most satisfactory. The communicating cross tube should be as short as possible so that the double tube may be held in the hand as conveniently as an ordinary test tube. Different media may be used on either side, either solid or liquid or a medium one side and some chemical on the other. The tubes should be plugged with rubber stoppers or sealed with paraffin or wax.

DR. A. PARKER HITCHENS,
Secretary

(To be continued)

SOCIETIES AND ACADEMIES

THE BIOLOGICAL SOCIETY OF WASHINGTON

THE 538th meeting of the society was held in the Assembly Hall of the Cosmos Club, Saturday, March 20, 1915, called to order by President Bartch at 8 P.M., with 45 persons present.

Under heading Brief Notes, General Wilcox called attention to a Cedar of Lebanon near Jackson's statue in Lafayette Square.

The first paper of the regular program was by T. S. Palmer, "Notes on the Importation of Foreign Birds." The speaker discussed the subject with special reference to canaries, parrots and game birds. He stated that about 500 permits for importation of birds are issued annually by the Department of Agriculture, the number of birds imported a year amounts to about half a million; as high as 17,000 birds have arrived in a single day; the number of species imported is about 1,500; canaries constitute by far the largest number brought in. Methods of breeding birds, caring for them in transit, selecting and teaching singers and talkers were explained. Dangers of importing contagious diseases as the "quail disease" and methods of quarantining were pointed out. The effect of the European war on the importation of birds was commented upon. Dr. Palmer's paper was discussed by the chair, Dr. Stiles and Mr. Goldman.

The second paper was by Ned Dearborn, "Notes on the Breeding of Minks in Captivity." Among the habits of the mink attention was called to
⁵ *Jour. Inf. Dis.*, Vol. 15, No. 1, July, 1914.

their profound diurnal sleep, cries emitted, polygamous nature, and cat-like character of food. The speaker stated that the period of gestation was found to be 42 days, number of young at birth 1 to 8; eyes of young remain closed for one month after birth; young may be weaned at 6 weeks; minks breed when a year old; and their fur is suitable for market at a year and a half, experiments showed that different types of diet had no effect on quality of fur. Speaker concluded that breeding of minks for commercial purposes was possible. Dr. Dearborn's paper was discussed by Messrs. Wetmore, A. B. Baker and Cooke.

The third and last paper was by M. W. Lyon, Jr., "*Endamæba gingivalis* and Pyorrhea." The speaker discussed the cause of pyorrhea or Rigg's disease, the *Endamæba gingivalis*, recently discovered by Dr. Allen J. Smith and others. He called attention to the pathologic lesions produced by the *Endamæba* and by the various bacteria associated with it; mentioned the amoebicidal action of emetin hydrochlorid administered systemically or locally; and reviewed some of the early references to the *Endamæba* before it was considered the cause of pyorrhea. The paper was illustrated by lantern slides of Gros's original drawing of the organism, and of several photomicrographs and drawings of living and stained *Endamæbas*, bacilli and spirochetes from a case of pyorrhea. Dr. Lyon's paper was discussed by Dr. Stiles and Mr. Goldman.

M. W. LYON, JR.,
Recording Secretary

WASHINGTON, D. C.

THE NEW ORLEANS ACADEMY OF SCIENCES

THE annual meeting of the academy was held on Wednesday, March 10, in Stanley Thomas Hall, Tulane University. The following officers were elected for the coming year: President, Dr. Gustav Mann; First Vice-president, Dr. R. B. Bean; Second Vice-president, Dr. W. O. Scroggs; Treasurer, Mrs. E. J. Northrup; Librarian, Professor H. F. Rugan; Secretary, R. S. Cocks. The paper of the evening was read by Dr. C. W. Duval on "Modern Conceptions which Tend to Explain the Occurrence of Secondary Infection in Typhoid Fever and Tuberculosis." There was considerable discussion of the paper in which Drs. Mann, Lemann, Friedrichs participated. At the close of the meeting refreshments were served and the Academy adjourned.

R. S. COCKS,
Secretary

THE CONTRIBUTION OF THE CHEMIST TO THE INDUSTRIAL DEVELOPMENT OF THE UNITED STATES¹

SINCE the outbreak of the European War, the American public has been led, adroitly or otherwise, to believe that industrial chemistry, that is, the industrial activity of the chemist, is limited to coal-tar dyes and that nothing should be regarded as industrial chemistry that does not deal with the manufacture of these dyes. Nothing could be further from the truth.

While it is true that the manufacture of coal-tar dyes forms an important branch of industrial chemistry, or of chemical industry, whichever you will, it by no means forms the whole of it or even a preponderating part of it.

From the economic point of view, economic effect and economic result is the measure to apply in determining economic importance and not the intellectual or scientific labor involved in the creation of that result.

From a strictly economic point of view coal-tar dyes can hardly be said to be vital or essential and by that I mean that we can get along without them and not suffer great hardship, personal or otherwise; anything of less need than that can hardly be called an economic necessity.

THE CHEMIST AND HIS WORK

The American public has seemingly given too little consideration to those industries of this country that make use of chemical knowledge and experience in the

¹ From the public address at the fiftieth meeting of the American Chemical Society, New Orleans, March 31 to April 3, 1915.

manufacture or utilization of products and yet these are the ones that compose chemical industry or industrial chemistry.

For the present, permit me to give in a few words the substance of the impressive series of papers presented at the meetings of this forenoon and this afternoon, and, as this presentation is being made, please have in mind the question as to whether you would prefer to have the United States able to produce all of its requirements of coal-tar dyes and *not* able to produce any of the various things which I am about to mention.

According to this symposium there are at least nineteen American industries in which the chemist has been of great help, either in founding the industry, in developing it, or in refining the methods of control or of manufacture, thus rendering profit more certain, costs less high and output uniform in standard amount and quality.

The substitution of accurate, dependable and non-failing methods of operation for "rule of thumb" and "helter-skelter" methods must appeal to every manufacturer as a decided advancement and a valuable contribution.

NINETEEN AMERICAN CHEMICAL INDUSTRIES

In presenting to you these various contributions of the chemist, I by no means wish to be understood as in any wise minimizing or reducing the contributions made to the final result by others, such as merchants, bankers, engineers, bacteriologists, electricians, power-men and the like; all that I wish to emphasize is that the chemist *did* make a contribution, and to that extent he is entitled to credit and acknowledgment.

The chemist has made the *wine industry* reasonably independent of climatic conditions; he has enabled it to produce substantially the same wine, year in and year

out, and no matter what the weather; he has reduced the spoilage from 25 per cent. to 0.46 per cent. of the total; he has increased the shipping radius of the goods and has made preservatives unnecessary.

In the *copper industry* he has learned and has taught how to make operations so constant and so continuous that in the manufacture of blister copper valuations are less than \$1.00 apart on every \$10,000 worth of product and in refined copper the valuations of the product do not differ by more than \$1.00 in every \$50,000 worth of product. The quality of output is maintained constant within microscopic differences.

Without the chemist the *corn products industry* would never have arisen and in 1914 this industry consumed as much corn as was grown in that year by the nine states of Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, New Jersey and Delaware combined; this amount is equal to the entire production of the state of North Carolina and about 80 per cent. of the production of each of the States of Georgia, Michigan and Wisconsin; the chemist has produced over 100 useful commercial products from corn, which, without him, would never have been produced.

In the *asphalt industry* the chemist has taught how to lay a road surface that will always be good, and he has learned and taught how to construct a suitable road surface for different conditions of service.

In the *cottonseed oil industry*, the chemist standardized methods of production, reduced losses, increased yields, made new use of wastes and by-products and has added somewhere between \$10 and \$12 to the value of each bale of cotton grown.

In the *cement industry*, the chemist has ascertained new ingredients, has utilized theretofore waste products for this pur-

pose, has reduced the waste heaps of many industries and made them his starting material; he has standardized methods of manufacture, introduced methods of chemical control and has insured constancy and permanency of quality and quantity of output.

In the *sugar industry*, the chemist has been active for so long a time that "the memory of man runneth not to the contrary." The sugar industry without the chemist is unthinkable.

The *Welsbach mantle* is distinctly a chemist's invention and its successful and economical manufacture depends largely upon chemical methods. It would be difficult to give a just estimate of the economic effect of this device upon illumination, so great and valuable is it.

In the *textile industry*, he has substituted uniform, rational, well thought-out and simple methods of treatment of all the various textile fabrics and fibers where mystery, empiricism, "rule of thumb" and their accompanying uncertainties reigned.

In the *fertilizer industry*, it was the chemist who learned and who taught how to make our immense beds of phosphate rock useful and serviceable to man in the enrichment of the soil; he has taught how to make waste products of other industries useful and available for fertilization and he has taught how to make the gas works contribute to the fertility of the soil.

In the *soda industry*, the chemist can successfully claim that he founded it, developed it, and brought it to its present state of perfection and utility, but not without the help of other technical men; the fundamental ideas were and are chemical.

In the *leather industry*, the chemist has given us all of the modern methods of mineral tanning and without them the modern leather industry is unthinkable.

In the case of vegetable-tanned leather he has also stepped in, standardized the quality of incoming material and of outgoing product.

In the *flour industry* the chemist has learned and taught how to select the proper grain for specific purposes, to standardize the product and how to make flour available for certain specific culinary and food purposes.

In the *brewing industry*, the chemist has standardized the methods of determining the quality of incoming material and of outgoing products, and has assisted in the development of a product of a quality far beyond that obtaining prior to his entry into that industry.

In the *preservation of foods*, the chemist made the fundamental discoveries; up to twenty years ago, however, he took little or no part in the commercial operations, but now is almost indispensable to commercial success.

In the *water supply of cities*, the chemist has put certainty in the place of uncertainty; he has learned and has shown how, by chemical methods of treatment and control, raw water of varying quality can be made to yield potable water of substantially uniform composition and quality.

The *celluloid industry*, and the *nitro-cellulose industry*, owe their very existence and much of their development to the chemist.

In the *glass industry* the chemist has learned and taught how to prepare glasses suitable for the widest ranges of uses and to control the quality and quantity of the output.

In the *pulp and paper industry* the chemist made the fundamental observations, inventions and operations and to-day he is in control of all the operations of the plant itself; to the chemist also is due the cheap production of many of the materials enter-

ing into this industry as well as the increased and expanding market for the product itself.

THE STATISTICAL POSITION

For the census year of 1909 the wage-earners and the value of manufactured products and the value added by manufacture in twelve of these industries and in the manufacture of chemicals is given in Table Ia.

this amounts to about 15 cents per person per year.

Now, which would you rather have, these thirteen industries with their \$2,500,000,000 worth of manufactured product or the coal-tar dye industry with its \$100,000,000 of product? The number of persons employed in these above thirteen industries is in excess of 500,000; the entire world's supply of coal-tar dyes is made by fewer than 40,000 people. Which would you rather have?

TABLE Ia

	Wage-earners	Product Value	Value Added by Manufacture
Wine	1,911	\$13,120,846	\$6,495,313
Copper	15,628	378,805,974	45,274,356
Fertilizer	18,310	103,980,213	34,438,293
Textiles	44,046	83,556,432	48,295,131
Canned and preserved foods	59,968	157,101,201	55,278,142
Cotton-seed oil	17,071	147,867,894	28,034,419
Cement	26,775	63,205,455	33,861,664
Sugar	20,730	327,371,780	52,523,806
Brewing	54,579	374,730,096	278,134,460
Leather	62,202	327,874,187	79,595,254
Glass	68,911	92,095,203	59,975,704
Paper and wood pulp	75,978	267,656,964	102,214,623
Chemicals (strictly)	23,714	117,688,887	53,567,351
Totals	529,823	\$2,455,035,132	\$897,688,496

TABLE Ib

Iron and steel	278,505	\$1,377,151,817	\$399,013,072
Petroleum refining	13,929	236,907,659	37,724,257
Lead smelting and refining	7,424	167,405,050	15,442,628
Illuminating and heating gas	37,215	166,814,371	114,386,257

Totals	513,020	\$2,605,262,886	\$829,052,389
Total for 31 chemical industries	1,042,843	\$5,060,298,015	\$1,726,740,885
Total for all industries	6,615,948	\$20,672,051,870	\$8,529,260,992

AMERICAN INDUSTRIES VS. COAL-TAR DYES

A most liberal estimate of the market value of the world's entire production of coal-tar dyes places it under \$100,000,000; the entire consumption in the United States is less than \$15,000,000, duty included, and

These thirteen industries employ 8 per cent. of all wage-earners in manufacturing enterprises in the United States, produce 12 per cent. of the total value of manufactured product and 10.5 per cent. of the total value added by manufacture. In

other words, the chemist engaged in these thirteen pursuits plays an important, if not indispensable part in the lives of 8 per cent. of our wage-earners and affects 12 per cent. of our manufacture-values and 10.5 per cent. of our values added by manufacture. But the total number of chemists makes up only about 0.01 per cent. of the population of the United States.

NO NATION CAN DO EVERYTHING ITSELF

Of course, it may be said that having made all these other things, there is no excuse why the American should not make coal-tar dyes in addition. Perhaps so; but nations, like individuals, can not each have or do everything. If each nation could do everything equally as well as every other nation, there would be no occasion whatever for international business. As this world is constituted, each nation does that which it can do the best and trades off the product for what some other nation can do better than it, and both sides are satisfied and make a profit; this is the same as the relationship between individuals. The shoemaker can make shoes better than he can bake bread; he makes shoes and exchanges part of his income with the baker for bread which the baker has made.

If American chemists can operate these industries better than or as well as other nations, it is no real ground for criticism that they can not do everything better than any other nation, any more than the shoemaker is to be criticized because he can not make as good a suit of clothes as can the tailor. If you want the shoemaker to be able to make a suit of clothes as well as the tailor you must provide him with the opportunity to learn how to tailor and take care of him while he is learning, and no doubt his suit of clothes will cost him more than it would cost an established tailor to turn out the same kind of a suit of clothes,

and you must again help your shoemaker while he is trying to market his suit of clothes against the established tailor.

EIGHTEEN ADDITIONAL AMERICAN CHEMICAL INDUSTRIES

The above nineteen American industries referred to by no means comprise all the American industries in which the chemist can be of help and of assistance. Many more are open.

A search through the census for 1909 discloses the eighteen additional industries listed in Table Ib which make use of chemists in the control of their operations.

In these eighteen additional industries the chemist affects 8 per cent. of our wage-earners, 12.6 per cent. of our manufacture values and 9.7 per cent. of our values added by manufacture. For these thirty-one industries, then, the 0.01 per cent. of chemists of our population directly affect 16 per cent. of our wage-earners, 24.6 per cent. of our manufacture values and 20.2 per cent. of our values added by manufacture.

This, therefore, is a measure of the influence of the chemist upon the industrial development of the United States; however gratifying this result is, it is nevertheless true that many other industries could employ chemical control to great advantage, if they only would, and many establishments under the above cited industries could, if they would, make use of chemical control. There is plenty of work left for the chemist to do in these industries to keep him fully and profitably engaged. This being so, why should he not continue to direct his energies to improving those things that he already can do, rather than attempt new and exotic things which others can do better than he?

THE FOREIGN BUSINESS

So much for our internal relations. How about our international relations? To an-

swer this question I will use the official classification of the German government as to what constitutes products of and for chemical industry and also the same government's corresponding figures for 1913.

No two countries, speaking through their statistical departments, have the same working definition of chemical industry. None of the official classifications is as comprehensive as is the official German classification. So far as the exchange of products and commodities involved in chemical pursuits is concerned, the German classification shows a total of 442 items of which 229 are involved in international trade between Germany and the United States. According to these figures and this classification, the United States imported from Germany in 1913, \$60,860,880, and exported to Germany \$156,036,090, or a total business of \$216,896,970, with a balance in favor of the United States of \$95,175,210. I have selected from this 1913 list of items of business between Germany and this country those whose gross is \$400,000 per annum or over (Table II).

It is interesting to note that we sell Germany more lard than Germany sells us of potash and aniline and other coal-tar dyes put together; that we sell Germany half again as much refined petroleum as it sells us aniline and other coal-tar dyes; that we sell Germany practically the same amount of pig and scrap lead as Germany sells us of alizarin and anthracene dyes; that we sell Germany almost as much paraffine as Germany sells us of indigo; and so on through the list.

RELATIVE QUALITIES OF IMPORTS AND EXPORTS

Of course, it will be contended that the things that we sell Germany are, from a chemical point of view, less refined, i. e., involve less hard chemical intellectual work than do our imports from Germany. But,

is most of the potash, which is practically mined from the ground in Germany, any more of a refined product than the phosphate rock we sell them? Does it not involve quite as much chemical ingenuity to produce good illuminating oil from petroleum as it does to produce many of the coal-tar dyes? There is no question that the general position above outlined is correct, namely, that our products, as a whole, are less refined than those that we get, as a whole, from Germany, but is that not true practically throughout our entire export and import business? Are not the textiles we export of a lower grade than those we import? Are not our leather products less refined than those we buy? And so on down the list. That being so, why pick out the chemist as a special mark for criticism when he is at least up to the average of his surroundings?

In 1913 the total foreign business of the United States amounted to \$4,277,348,909, and the excess of exports of all kinds over imports of all kinds amounted to \$691,271,949.

The trade in chemicals and products of and for chemical industry between the United States and Germany in 1913 furnished 5 per cent. of that total of international business and provided 13.8 per cent. of the balance of trade.

THE INFLUENCE OF THE CHEMIST

The symposium of papers presented to-day constitutes a record of proud achievement, of solid accomplishment in nineteen different branches of American industrial activity, to which advance the application of chemical knowledge, chemical principles and chemical experience by American chemists, has contributed a noble share and an effective part. It is perhaps true that much of that progress would have come without the American chemist, but it is

TABLE II
U. S. Chemical Trade with Germany (1913)

U. S. Imports from Germany	Value in U. S. Money	U. S. Exports to Germany
	\$75,000,000	1 Copper
	20,700,000	2 Lard
1 Potash salts	18,819,000	3 Refined petroleum
2 Aniline and other coal-tar dyes	12,690,000	4 Phosphate rock
	7,290,000	5 Oleomargarine
	4,970,000	6 Turpentine resin
	4,880,000	7 Mineral lubricants
	4,585,000	8 Spirits turpentine
3 Caoutchouc	4,460,000	
	3,840,000	9 Crude benzine
	2,582,000	10 Beef tallow (prime)
	2,220,000	11 Nickel and nickel coin
	2,171,000	
	1,744,000	
4 Straw, esparto and other fibers; paper stock	1,640,000	12 Cotton-seed oil
5 Alizarin and anthracene dyes	1,550,000	
	1,463,000	13 Pig lead and scrap
6 Indigo	1,421,000	
	1,319,000	14 Crude and hard paraffin
	1,231,000	15 Acetate of lime
	1,162,000	
7 Platinun. and allied metals	1,120,000	
8 Hops	952,000	
9 Miscellaneous volatile oils	941,000	16 Tin and tin scrap
	903,000	
10 Tin and tin scrap	900,000	
11 Potassium and sodium cyanide	845,000	
12 Chrome, tungsten, etc.	784,000	
13 Superphosphates	766,000	
	724,000	17 Crude wood alcohol
14 Beet sugar, refined	716,000	
	695,000	18 Carbides
	673,000	19 Miscellaneous volatile oils
15 Alkaloids exc. quinine	672,000	
16 Toilet and tooth powders	658,000	
	656,000	20 Heavy benzine and patent naphtha
17 Lime-nitrogen, etc.	635,000	
18 Potash carbonate	632,000	
	617,000	21 Lubricants of fats and oils
	579,000	22 Beef and mutton tallow
19 Ferro-Al, Cr, Mn and Ni	567,000	
20 Potassium magnesium sulfate	509,000	
21 Gold ores	506,000	
	506,000	23 Copper alloys
22 Beet sugar, raw	492,000	
23 Aniline oil and salt	476,000	
24 Bronze and metal colors	473,000	
25 Glue	471,000	
26 Aluminum plates and metal	454,000	
27 Quinine and its salts	436,000	
	422,000	24 Portland cement
28 Terpeneol and allied synthetics	409,000	
29 Gelatin	403,000	

equally true that under those conditions the advance would have been much slower and also much of what has been accomplished would never have happened at all without the faithful, enthusiastic and alert

cooperation of the American chemists on the job. With such a record, the American chemist can hold up his head with pride and self-confidence, firm in the belief, and warranted in his conviction that he has done

a man's work, in a man's way, that he has not been an idler, nor a sloth, nor a drone, but that he has been one of the busiest of busy workers, with a keen eye and an alert intellect, always searching for an opportunity for the betterment of his industry, and for improvement of the conditions of his fellowman.

GERMAN SUPREMACY

That the chemist has not done more is by no means due to any unwillingness. It is due in the largest part to the apathetic attitude of those in charge of the management of many of our industrial enterprises requiring chemical knowledge in their exploitation. Many of these men in responsible positions do not have a chemical education even along the lines in which they are financially active. In those cases chemical novelties and chemical problems are not passed upon, on their merits, by chemists or by men with a chemical point of view, but by merchants, by lawyers and by bankers, men who, by their very training, are not capable of taking the chemist's point of view, of having the chemist's sense of proportion, and are unwilling to take a chemist's chance in a chemist's way. Therein lies, perhaps more than in any other one thing, the reason for Germany's supremacy in most of the branches of chemical industry. That also is the reason for the success of a great many of our own huge transportation, electrical and chemical enterprises. The business is run by men who know it from the technical point of view. Railroads are run by men who know the railroads from the operating and construction point of view; electrical enterprises by men who know the business from the electrical engineer's point of view, and they make their enterprises take their business chances in a transportation way, and in an electrical way. Practically all of our

chemical enterprises that have been managed in the same manner have also been successful, but there is still great room for improvement, and just as soon as that improvement is accomplished, just so soon, and no sooner, will there be less and less talk about the incompetency of the American chemist. German chemical enterprises are run and managed by chemists.

Some years ago I was thrown in company with a very successful meat packer, and a very successful metallurgist; the packer asked me when chemists would make glycerin synthetically and make it cheap, as the price of glycerin was getting to be altogether too high; the metallurgist asked me, rather impatiently, what elements make up glycerin; somewhat dazed, I replied, "Carbon, hydrogen and oxygen." Thereupon the metallurgist said to the packer, "Why, carbon is coal, hydrogen and oxygen are water, both are plentiful and cheap; I do not see why these chemists can not mix coal and water and produce glycerin." I felt that my life was altogether too short to attempt to educate those two very successful men to a proper appreciation of the difficulties of converting coal and water into glycerin. This metallurgist's answer to the packer might with equal truth have referred to such dissimilar things as wood alcohol, grain alcohol, vinegar, olive oil, castor oil, whale oil, starch, camphor, cane sugar, beet sugar, grape sugar, carbolic acid, alizarin, and host upon host of similarly different things. I do not know whether that packer, when he got home, told his chemist to take a hunk of coal and drop it into a bucket of water, and make glycerin. I hope, for the chemist's sake, that he did not give him that task.

THE RESPONSIBILITY OF MANAGERS

If there is such a misconception of the chemistry underlying their own products

of manufacture on the part of many of our manufacturers, as this meat packer displayed, and if the general chemical viewpoint of the managers of many of our chemical industries is as confused and unfounded as was the view of this metallurgist, then it is no wonder that American chemical enterprises are behind some other countries; the real wonder is that we have any chemical industry at all. Nor is there any dearth in this country of properly trained chemists. There are almost ten thousand of them now in the United States, and they are being turned out by our technical and other schools with great regularity and with increasing volume every year. The fault is not with the American chemist, nor with his ability, nor his willingness; the fault lies principally and almost wholly with those in charge of many of our industrial enterprises, who fail absolutely in a chemical understanding of their own products and are devoid of any sympathetic contact with chemistry and with chemical points of view and therefore are incapable of, and unable to appreciate the value of chemical work or to have a wholesome understanding of the snares, the pit-falls and the tedium of chemical research.

CHEMISTS IN MANAGERIAL POSITIONS

This plea for the wider introduction of chemists in positions of managerial responsibility is, however, not to be interpreted into a statement that any kind of a chemist can do any kind of a chemical job. Just because a man can swing a scythe and cut wheat rapidly is no reason why he should be entrusted with the job of giving a man a shave; therefore, if you have a cotton oil problem, do not give it to a man whose specialty and training is in iron and steel only. The non-chemical managers of chemical enterprises will have their hands full picking out the right chemist for the right job

and training promising chemical material for managerial positions. To do this successfully is quite an undertaking and will not be accomplished without many trials and many failures. Why should there not be failures? Not every man who is sent out on the road makes a successful traveling salesman, nor is every man put in as a superintendent a success as a superintendent.

In selecting your chemist for a responsible position, you must look out that you do not get a square peg for a round hole, just as you would when engaging a man for any other position, but the trouble seems to be with many of those who have engaged chemists, that they have not appreciated that there are chemists and chemists; they seem to have some sort of an idea that there is a magic about what a chemist does. Now, there is no magic at all. It is all plain, hard work, that calls for a lot of intellectual effort, and above all, the application of common sense, which, as every one knows, is a very rare article.

THE RESPONSIBILITY OF THE PUBLIC

With this record of solid achievement placed before you to-day, together with what I have just said, I hope that the conviction will finally break through, and will penetrate the public mind as well as the minds of those in charge of many of our industrial establishments, that if the American chemist is not doing as much as the public expect him to do, it is because the public through its industrial enterprises has deliberately declined to give him a chance. With this wonderful record of fruitful endeavor is the American chemist to have his chance? The answer to that question is largely in the hands of the American public.

However, the public will have to acquire in some dependable way an appreciation of what the chemists' work stands for and

really is. There are numerous difficulties in the way. By its very nature, the work of the chemist is more or less concealed from public inspection. If you have a particularly well tanned piece of leather, the lay-person thinks no further than that it is a pretty good job, and is utterly unable to appreciate the large amount of work that has been necessary to produce or to create the way of making that particularly good piece of leather. There is nothing so conspicuous about the chemist's work as there is, for example, about the bridge builder's work, or about the work of a man who erects a skyscraper. The chemist's work, as a whole, does not fill the eye nor appeal to the imagination; and not filling the eye, and not appealing to the imagination there is really no practical method of valuation easily accessible to the ordinary individual; not only is the ordinary individual incapable of such a valuation, but even men high in industrial pursuits have not that particular intellectual vision which permits them to appreciate the real significance behind any given chemical product. The only exception hereto seems to be coal-tar dyes.

The reason for this exception is not hard to find. Could anything appeal more to the imagination than the conversion of such a disgusting, sickly mess as coal tar into brilliant colors that rival and excel every tint and shade in nature?

THE RESPONSIBILITY OF THE CHEMIST

However, the chemist must not attempt to absolve himself from all responsibility for the prevailing lack of appreciation or skepticism among capitalists and bankers of the value of chemical work in industrial operations. While competent chemists and chemical engineers by their very effective work have wrung from reluctant financial men proper acknowledgment of the value of chemical examination, control and manage-

ment of enterprises requiring such, yet the work has not gone far enough, and it is not at all unusual for financial men to support with might and main enterprises which any qualified chemist or chemical engineer could and probably did tell them were foredoomed; also it must not be forgotten that qualified chemists and chemical engineers, like other professional advisers, have gone astray in their calculations and have supported enterprises which ultimately failed. The mining, electrical and railroad engineers finally succeeded in obtaining their present influential position among the industrial councils of this country and with the brilliant success of the chemical engineers of Germany in the same direction it is not too much to hope that ultimately the American chemist and chemical engineer will come into his own. When he does, there will be far fewer exploitations than heretofore of the wild and fantastic schemes of chemical enterprise now so easily financed by the gullible portion of our investing public and fewer and fewer failures of chemical enterprises undertaken in good faith and serious mood.

Therefore, let every chemist in advising on chemical operations prominently bear in mind that failure to give correct advice not only reacts upon him but upon each and every member of the chemical profession and merely helps to postpone the day when the chemist will come into his proper position among the makers of the nation.

CONCLUSION

To bring the matter up squarely before you let me recapitulate: The 10,000 chemists in the United States are engaged in pursuits which affect over 1,000,000 wage-earners, produce over \$5,000,000,000 worth of manufactured products and add \$1,725,000,000 of value by manufacture each year; the business in products of and for chem-

ical industry between the United States and Germany alone in 1913 provided 5 per cent. of our total foreign business and 13.8 per cent. of our balance of trade for that year. Please bear in mind that I am not by any means attempting to claim all the credit for this for the chemist; all that I ask is that his claims to recognition for intelligent, active and effective collaboration in bringing about those stupendous results be not thrown aside as worthless and that he shall not be made the target of unjust criticism because in 1914 there was a shortage of about \$600,000 or 7 per cent. in coal-tar dyes and because cotton dropped from 15 cents to 6 cents.

Much more could be said of the chemist and his contribution to the effective every day labor of this work-a-day world but time and space forbid. I am sure that this short sketch of the chemist's activities, his hopes, his aims and his work will serve to create a wider interest in him and will result in according to him the credit to which he is entitled, namely, that he pulls more than his own weight in our nation's boat.

BERNHARD C. HESSE

THE GRAY HERBARIUM

THE rebuilding of the Gray Herbarium, which has been in progress for some years, has just been finished by the completion of the main central section of the building. The original structure, the gift of Nathaniel Thayer in 1864—at which date Dr. Asa Gray gave his invaluable botanical collections to Harvard University—was a brick building and for its time substantial, but the entire interior finish, including the floors, the plant cases, book shelving, etc., was of wood. The building had become wholly inadequate for the growing collections and was far from being fireproof in any modern sense.

The complete rebuilding and considerable enlargement was begun in 1909 and has been carried out a section at a time. It has been effected through the generosity of members of the

visiting committee. The initial step consisted in the erection of a substantial ell, known as the Kidder wing, the gift of Mr. Nathaniel T. Kidder, of Harvard, '82. This wing, completed in 1910, provided convenient shelving space in exceptionally secure cases for more than 300,000 sheets of herbarium specimens as well as a portion of the library, thus giving great relief from the congestion of the older building.

In 1910 the adjacent residence, formerly occupied by Dr. Gray, was moved to the opposite side of Garden Street, and in its place was built in 1911 the Library wing of the herbarium. This portion of the building, furnishing ample quarters for the convenient shelving of the library, with extensive provision for its growth, was given anonymously and was completed in 1912. Last year, however, the donor, Dr. George Golding Kennedy of the Harvard class of '64, kindly consented that his name might be announced in connection with the fiftieth anniversary of the graduation of his class.

This wing contains, besides the library, the private offices of the curator, Professor B. L. Robinson, and the librarian, Miss Mary A. Day, a room for maps, files and publications, and, in the basement, a press-room for the drying and preparation of specimens, a photographic dark-room, a staff-room and store room.

At the same time, the old and wholly inadequate laboratory and auditorium, which had formed the opposite wing of the earlier structure and had been built in 1871 by the gift of Horatio Hollis Hunnewell, were taken down and replaced by the George Robert White Laboratories of Systematic Botany, a wing of much greater capacity, well arranged, well lighted and provided with complete and highly perfected equipment for its purposes. This wing, the gift of Mr. George Robert White, of Boston, contains on the ground floor two laboratories, one used by the Harvard students in systematic botany, the other by the Radcliffe students. On the second floor, there is an instrument room, a "bundle-room" for the safe storage of collections awaiting study,

labeling, distribution as duplicates, etc., also Professor M. L. Fernald's private office, and finally a large and fully furnished room, which has been placed at the service of the New England Botanical Club for its extensive and valuable herbarium.

In 1912, by a second gift from Dr. George G. Kennedy, it was possible to carry out another highly important step in the general plan of reconstruction by rebuilding of the front portion of the original structure, raising it from one and a half to three stories in height and furnishing accommodations for an exceptionally convenient mounting room, a coat-room, a private office, a room for the collection of "box material" (i. e., fruits, nuts, cones, etc., which from form and thickness can not be readily affixed to the ordinary herbarium sheets), and a room for the Pteridophyta and Gramineae.

As these successive additions were made to the earlier building, the collections both of specimens and books had been so far as possible removed from the old central portion to the surrounding new and fireproof wings. Early in 1914 the last part of the old building, namely the main central room, a story and a half structure, with narrow wooden gallery, was taken down, to be replaced by a structure of greater height and much more substantial construction. This final portion of the building is now completed. It and its steel furnishings have been the gift of Mr. White, Dr. Kennedy, Mrs. William G. Weld, Miss Susan Minns and Mr. John E. Thayer. As rebuilt this main room is furnished with two steel and glass galleries, of convenient breadth, each provided like the ground floor with a series of steel herbarium cases. The room is further furnished with blocks of table-topped cases, rising to counter height; also with large steel tables, covered with battleship linoleum and of height convenient for microscopic work and plant-dissection. The room is provided with copious north light, as well as overhead light. The well lighted basement of this section of the building has been furnished as a sorting room and to that end has been provided with thirty tables which together furnish

room for more than two hundred piles of herbarium sheets and thus permit even the more complicated kinds of sorting without crowding or overlapping. These basement tables are made of "transite," a neat light gray stone-like material made of Portland cement and asbestos fiber.

Although the reconstruction has thus proceeded by sections, the building has lost nothing in unity, for the whole was carefully planned at the outset and each successive portion was built with due regard to its relation to the whole structure. In the whole process of building and furnishing there has been a strenuous effort to eliminate woodwork and all combustible materials. The building itself is of brick with floors and roof of reinforced concrete. All doors, jambs, sash and window frames are bronze, copper or steel-sheathed. There is no exposed woodwork in any part of the building, inside or out. As to the furnishing there has been the same attention to safety. All the plant cases, work tables, desks, book-shelving, files, wall cabinets, etc., built to order by the Art Metal Construction Company, of Jamestown, New York, are of steel, for the most part enameled in agreeable shades of gray-green or deep green with bright or oxidized brass trimmings. Even the wastebaskets are of metal. At some points in the furnishing it has seemed best and entirely safe to make certain concessions to comfort and sentiment. Thus the chairs are still of wood, the window-shades are still of linen (though they are on metal rollers), and in the curator's office some articles of wooden furniture formerly belonging to Dr. Gray are kept in consequence of association and sentiment. Furthermore, no substitute for wooden picture frames has been found, at least none which has proved esthetically agreeable. With these trifling exceptions, however, all combustible materials have been scrupulously avoided.

The herbarium itself, i. e., the great collection of dried plants mounted on sheets of cardboard, would of course prove highly inflammable, but it is preserved in cases which form, as one may say, so many fire-tight compartments, so that even were a fire by some accident started it could not possibly spread.

Although the primary ideals followed in the rebuilding of the Gray Herbarium have been those of safety, permanence and convenience of arrangement, the resulting structure though architecturally plain is by no means homely. Indeed, its good proportions, dignified simplicity and obvious solidity give it a pleasing effect. It is a building to which the architect, Mr. W. L. Mowell, of Boston, has given a good balance, but it has purposely been kept from absolute symmetry from a feeling that such initial symmetry, if attempted, would render it much more difficult to make future additions, as these prove needful with the growth of the collections.

It is a notable fact that during the complete rebuilding of the establishment, the Gray Herbarium and its library have been open as usual for consultation. Though several reshelfings and transfers of materials from one section to another have of course been needful and demanded the care and attention of the staff from time to time, nevertheless the scientific work of the staff, students and visiting specialists has proceeded with surprisingly little interruption. The building has been continuously occupied and when it is borne in mind that much of the new structure has been built upon the old foundations, it will be seen by the many botanists for whom the earlier building had many pleasant sentiments and associations, that it is perpetuated rather than replaced by the new one.

ELISHA WILSON MORSE

ELISHA WILSON MORSE, formerly instructor in natural history at the Bussey Institution of Harvard University and well known for his contributions to the history of domesticated animals, died in Washington, D. C., on April 18, from pneumonia.

During the past few years Mr. Morse served as a specialist in animal husbandry in the U. S. Department of Agriculture. Aside from his official duties as an associate editor of the *Experiment Station Record* and later as a scientist in the U. S. Dairy Division, he was especially active in putting the foundations of animal breeding and feeding on firmer

bases. He was one of the few who had a keen appreciation of the value of applying sound biological and statistical principles to the interpretation of feeding trials.

Mr. Morse was a graduate of the class of 1897 of Harvard University, an active member of the Biological Society of Washington, the American Society of Animal Nutrition, and the Boston Society of Natural History, and a regular contributor to several standard year books and encyclopedias.

LEWIS WILLIAM FETZER

SCIENTIFIC NOTES AND NEWS

THE presidency of the German Association of Scientific Men and Physicians, vacant by the death of Professor Eberhard Fraas, has been filled by the vice-president, Dr. F. von Müller, professor of internal medicine at Munich.

THE annual address before Sigma Xi and Phi Beta Kappa of the University of Illinois, which in previous years has been given during commencement week, will be given this year on May 4, by Dr. George Otis Smith, director of the U. S. Geological Survey. The subject is "Practical Ideals."

DR. JULIUS HIRSCHWALD, professor of geology and mineralogy in the Technical School at Berlin, has been given the doctorate of engineering by the Technical School of Dantzig, on the occasion of his seventieth birthday.

At the meeting of the Entomological Society of France, on January 27, the committee appointed to nominate an honorary member in place of the late M. J. Perez reported that, while custom decreed the election of a Frenchman to fill this vacancy, it appeared to the committee as very proper, under existing conditions, to break away for once from the traditions and custom of the society and to give this honor to M. A. Lameere, professor in the University of Brussels, as an especial testimony of the sympathy and esteem of the society for one of the most eminent representatives of Belgian entomology.

DEAN EDWARD ORTON, JR., of the College of Engineering of the Ohio State University, has

been granted leave of absence for next year, but expects to remain at Columbus. Professor Edwin F. Coddington, of the department of mechanics, now secretary of the college, will be acting dean next year. Professor Charles C. Morris, of the department of mathematics, will fill the new position of assistant to the dean.

DR. EDMOND W. WILSON has been promoted to the position of assistant superintendent of the Boston City Hospital, filling the vacancy caused by the resignation of Dr. Frank H. Holt, who has assumed his new duties as superintendent of the Michael Reese Hospital, of Chicago.

DR. ROY K. FLANNAGAN, of Richmond, has been appointed assistant commissioner of health of Virginia, succeeding Dr. Allen W. Freeman, who resigned to accept the position of epidemiologist in the United States Public Health Service.

DR. PHILIP J. CASTLEMAN has been appointed director of the bacteriological laboratory of the Boston Board of Health to succeed Dr. James J. Scanlon, who died a short time ago.

DR. ALBION W. HEWLETT, professor of medicine at the University of Michigan, has been appointed visiting lecturer on medicine at the Harvard Medical School, and is to serve as visiting physician at the Peter Bent Brigham Hospital.

MR. WILLIAM HARPER DAVIS, of Philadelphia, at one time assistant in psychology at Columbia and instructor and professor in philosophy and psychology at Lehigh University, secretary of the American Psychological Association, etc., who has latterly been engaged in business, has accepted the position of librarian to the Public Service Corporation of New Jersey. His address after September 1 will be the company's office, Newark, N. J.

SIR RUPERT CLARKE, who in the summer of last year led an expedition up the Fly River in British New Guinea, has returned to London.

DR. DAVID L. EDSALL, professor of clinical medicine at Harvard Medical School, delivered the annual address of the Pathological Soci-

ety of Philadelphia on April 22, his subject being "Bearings of Industry upon Medicine."

SINCE Easter, Professor George Grant MacCurdy, of Yale University, has lectured on "The Dawn of Art" for the Archeological Institute of America at Richmond, Va., Washington, D. C., and Rochester, Auburn, Syracuse and New York, N. Y.

MAJOR SAMUEL FLOOD-PAGE, who was active in development of electric lighting and wireless telegraphy, died on April 7, aged eighty-one years.

PROFESSOR KARL THEODOR VON HEIGEL, president of the Bavarian Academy of Sciences, has died at the age of seventy-three years.

THERE have been killed in the war Dr. Fr. Ostendorf, professor of agriculture in the Technical School at Karlsruhe; Dr. Hans Hammerl, associate professor of hygiene at Graz, and Dr. August Wolkenhauer, docent for geography at Göttingen.

THE Serbian typhus epidemic may be controlled if the proper equipment is made available, according to a cablegram received on April 29 from Dr. Richard P. Strong, head of an American commission recently sent to Serbia by the American Red Cross, assisted by the Rockefeller Foundation and the Serbian relief committee. Messages received at the headquarters of the American Red Cross announce that an international board of health has been formed at Nish. The president of the international board is Prince Alexander of Serbia, the vice-president, Sir Ralph Paget of England. Dr. Strong was made medical director of the board, and the members include the heads of the French, Russian and English sanitary commissions. Dr. Strong, who is professor of tropical diseases in Harvard Medical School, appeals for more doctors and sanitary and medical equipment and declares that if Dr. William C. Gorgas, surgeon-general of the United States Army, will accept a commission in combating the typhus in Serbia, the international board just formed will make him medical director and Dr. Strong will serve as his assistant. The remainder of the American commission, which numbered ten sanitarians

and bacteriologists, have reached Salonica, Greece, and will join Dr. Strong at Nish shortly.

A MAJORITY of the members of the board of regents of the University of Minnesota, sitting as the executive committee of the board, has voted unanimously to adopt the following statement of purpose:

Although the board of regents has not as yet officially considered a proposed affiliation with the Mayo foundation, in order to make clear the policy of the board, be it voted:

"First, that in any event the regents do not enter into any permanent arrangement within four years;

"Second, that the board enter into no permanent affiliation which does not give the regents complete control, within the specific purposes of the foundation, of the endowment funds administration, and teaching."

By a vote of 36 to 31 the state senate has passed a bill as follows: The board of regents of the University of Minnesota shall not affiliate or unite with any persons, firm or corporation under any agreement, arrangement or understanding which will preclude the board from exercise of any of its functions in the educational management and control of the university or any of its colleges, schools or departments. But this act shall not be so construed as to disable the said board from employing or authorizing the employment of instructors, lecturers or teachers who shall devote a part only of their time or service to the educational work of any department of the university.

A CONFERENCE of the Massachusetts Association of Boards of Health and the State Department of Health and voluntary organizations interesting themselves in matters of public hygiene was held in Boston on April 29. The speakers at the forenoon conference were Governor Walsh, Commissioner Allan J. McLaughlin, Dr. Charles W. Eliot, Professor Irving Fisher, Miss Ella P. Crandall, executive secretary of the national organization of Public Health Nursing, and Professor William T. Sedgwick, president of the American Public Health Association. This was followed by a business session over which Professor M. J. Rosenau, of Harvard University, presided.

The speakers of the afternoon, and their subjects, were: "The Control of Communicable Diseases," Dr. Eugene R. Kelley, State Department of Health; "The Relationship Between the State and Local Boards of Health," Dr. Lyman A. Jones, district health officer, Berkshire district; "The Health of the Farmer," Dr. John S. Hitchcock, district health officer, Connecticut Valley District; "The Vacation Health Problem," Dr. Adam S. MacKnight, district health officer, southeastern district; "The Continuing Problem of Vaccination," Dr. Samuel H. Durgin, former chairman of the Boston Board of Health; "The Control of Cancer," Dr. Edward Reynolds, vice-president American Society for the Control of Cancer; "Some Problems of the Health Officer of a Small City," Dr. Francis G. Curtis, health officer, Newton; "Infant Mortality from the Standpoint of the State," Dr. William Hall Coon, district health officer, northeastern district.

The Entomological Society of France, in January, took a ballot by mail among its active membership on the question of expelling all German members. The result of the ballot, just announced, was as follows:

Total number of ballots cast	270
For the immediate expulsion of all German members	186
For their expulsion after investigation	103
<i>Statu quo</i> until end of hostilities	37
Provisional expulsion	1
Blank ballots	3

Inasmuch as there was no majority in the whole number of ballots cast in favor of immediate expulsion *en bloc*, the question was referred back to the council to consider the spirit and the letter of the vote and the conditions under which the German members should be expelled.

THE United States Geological Survey opened on May 1 a district office at Boston, Mass., from which investigations of the water resources of the New England states will be carried on. For several years the Geological Survey has made measurements of the flow of streams in New England, the work being carried on from the district office at Albany, N. Y. The establishment of a district office at

Boston will make possible the extension of the work and will greatly facilitate the investigations. The states of Massachusetts, Maine and Vermont are cooperating in these investigations, and a bill is pending before the legislature of New Hampshire providing for co-operation in that state. Charles H. Pierce, district engineer of the Geological Survey, will be placed in local charge of the work.

THE committee on arrangements give notice of change in date in the Interstate Cereal Conference in California previously announced in *SCIENCE* and also a change in one of the localities from Merced to Stockton as follows: The first day's meeting will be held at Stockton, Tuesday, June 1, for inspection of San Joaquin Valley cereals, while the following three days will be spent as previously stated, namely, the second day, June 2, at Berkeley, beginning the program of the conference; June 3 at Davis, finishing the program and inspecting the university farm, and the last day, June 4, at Chico, where the program, if still unfinished, can be concluded. At this place also an inspection will be made of the Plant Introduction Garden and the cereal experiment plats of the U. S. Department of Agriculture. During the day, those who desire to do so can also go the short distance to Biggs to inspect the rice experiment farm at that place.

SINCE the time of Captain Cook the Hawaiian Islands have been visited by geologists and others interested in the problems of volcanoes, and much has been written concerning them. Recently the United States Geological Survey has taken up the investigation of the islands from various economic and scientific points of view and is preparing topographic maps, which are necessary for many kinds of work. It has been found that the geologic history of the islands is by no means so simple as was supposed from the earlier publications concerning them. In Professional Paper 88, "Lavas of Hawaii and their Relations," by Whitman Cross, which has just been issued, the survey is presenting a summary of what is now known concerning the lavas of all the islands. This paper is largely technical in its character, for it is intended primarily to serve as a basis for future study of the rocks by

geologists, but for any one interested in the various islands and not following strictly the tourist route there is considerable general information, not to be found elsewhere. The work is a summary of earlier publications supplemented by the author's own observations on the four largest islands—Hawaii, Maui, Oahu and Kauai. It appears that there are many other kinds of lavas in Hawaii besides basalt, and many facts of association of the different lavas are of interest to students of the inner history of volcanoes. While much is yet to be learned concerning the lavas of these islands, Mr. Cross shows that present knowledge of the rocks is sufficient to throw light on some of the most vexed questions pertaining to the origin and relations of the igneous rocks of the earth. The chemical relations are discussed with particular thoroughness. Petrologists will find valuable material in this report, bearing on many problems.

THE shortage of potash salts in the United States in 1914 was further accentuated by the German embargo on export at the end of January, 1915. In spite of the interruptions to the normal trade in potash salts, the imports of salts proper in 1914 amounted to 485,818,459 pounds, valued at \$8,743,973, according to a statement by W. C. Phalen, just made public by the United States Geological Survey. These figures represent a decrease in quantity and value amounting to 21 per cent. and 19 per cent., respectively, compared with 1913. These figures, however, do not represent the total imports of potash salts. There should be added the quantity and value of kainite and manure salts imported, amounting in 1914 to 482,876 tons, valued at \$3,397,590, making a total importation during the year valued at \$12,141,563, compared with \$15,241,152 in 1913—a decrease amounting to \$3,099,589 or approximately 20 per cent. Potash salts constitute only one of several fertilizers imported. Bone dust, calcium cyanamid or lime nitrogen, guano, basic slag and other materials used for manure are also brought in. The total quantity of these materials including kainite and manure salts imported in 1914 was 761,896 long tons, valued at \$9,921,439. In addition to the above importations, sodium nitrate

valued at \$15,204,539 came into this country from foreign lands, thus bringing the total value of imports as designated above up to \$33,869,951.

UNIVERSITY AND EDUCATIONAL NEWS

MR. ANDREW CARNEGIE'S gifts to the Carnegie Institute and Institute of Technology have now reached a total of \$27,000,000, his latest contribution announced at Founder's Day, on April 29, being \$2,700,000. Of this latter amount \$1,200,000 is for new buildings and \$1,500,000 for endowment. The address at the Founder's Day exercises was delivered by Dr. Romulo S. Naon, the Argentine ambassador, who spoke on "The Triumph of True Pan-Americanism and Its Relation to World Peace."

THE campaign to raise \$1,385,000 for the Stevens Institute of Technology in Hoboken, N. J., has been successfully concluded. The entire indebtedness of the college, amounting to \$385,000 has been cancelled, leaving \$1,000,000 to be used for the erection of new buildings and for endowment.

THE University of Pennsylvania, Columbia University and the Stevens School of Technology mechanical engineering departments have received funds amounting to \$5,000 each, in accordance with the provisions of the will of the late Admiral George W. Melville.

GIFTS amounting to \$72,908, to be devoted to cancer research at the Harvard Medical School, have been announced. Of this sum \$50,000 is provided by the will of Philip C. Lockwood, of Boston.

THE new buildings of the medical school of Washington University, St. Louis, were dedicated on April 29. The three large buildings, which contain laboratories, dispensaries, lecture rooms and libraries, cost \$1,200,000 and, with the new Barnes Hospital, the St. Louis Children's Hospital and St. John's Hospital, form an important group of buildings devoted to medical and surgical purposes. Addresses were delivered by Dr. William Henry Welch, professor of pathology at Johns Hopkins University; by President A. L. Lowell, of Harvard University; by Dr. Henry S. Pritchett,

president of the Carnegie Foundation for the Advancement of Teaching, and by President George E. Vincent, of the University of Minnesota.

THE University of South Dakota has completed the erection of a fireproof chemical laboratory at a cost of \$100,000.

THE thirty-fourth session of the legislature of Nebraska recently adjourned appropriated the sum of \$150,000 for the erection of a teaching hospital on the campus of the University of Nebraska College of Medicine at Omaha, Nebraska. The appropriation has been approved by the governor.

THE tuition fee at Harvard University has been increased to \$200, which will take effect at the beginning of the year 1916-17, but will not apply to a student now registered, unless he changes his department. No infirmary, laboratory or graduation fees will be charged.

PROFESSOR IRA C. BAKER has resigned his position as head of the civil engineering department of the University of Illinois, which he has held for thirty-four years. He will continue to give a limited number of courses. Dr. F. H. Newell, consulting engineer of the U. S. Reclamation Service, has been appointed to succeed Professor Baker as head of the department of civil engineering. He entered upon his work at the university on May 1.

DR. ANDREW HUNTER, of the medical department of Cornell University, has accepted an appointment to the chair of pathological chemistry in the University of Toronto.

DR. A. A. KNOWLTON, associate professor of physics at the University of Utah, has been elected professor of physics at Reed College. It will be remembered that Dr. Knowlton was not reelected at the University of Utah because of the president's charge that he had made remarks unfavorable to the administration of the university. President Foster of Reed College went to Salt Lake City to investigate the situation. He talked with both factions of the board of regents, with many members of the faculty, including those who have resigned and those who have not, with other citizens, with students and with the president.

As a result of this investigation at first hand, Dr. Foster was convinced that Dr. Knowlton and the other men of the faculty at Salt Lake City have assumed no greater freedom of speech than every member of the Reed College faculty has as a matter of course.

DISCUSSION AND CORRESPONDENCE

ON THE PRODUCTION OF RARE GASES IN VACUUM TUBES

TO THE EDITOR OF SCIENCE: A number of investigators, among them Sir J. J. Thomson, Sir W. Ramsay, Winchester, and Collie, have found that helium and neon are produced in vacuum tubes by electrical discharges. These gases were not accompanied by argon, and therefore not due to leaks in the apparatus.¹ A thoroughly satisfactory explanation of the appearance of the gases remains to be given, although a very plausible hypothesis has been advanced by Professor Winchester. Winchester² finds that helium and neon are given off from aluminium electrodes only during the first few hours of long-continued discharges, and he therefore concludes that the gases must have been occluded on the surfaces from the atmosphere.

This explanation agrees with a number of facts. For example, we may explain a *second* liberation of helium and neon, sometimes noticed in vacuum tubes after many hours' continuous running, by supposing that a surface layer (*e. g.*, slag), imbedded in the metal when it was poured, becomes exposed when the electrode is partly "spluttered" away. The non-appearance of these gases when very heavy discharges (*i. e.*, large currents) are used, as in one experiment with uranium, by Collie,³ would mean that the surface layer is spluttered away before any considerable amount of gas has been liberated.

There is an alternative explanation which

fits the facts equally well, if we admit the possibility of changes of a radioactive nature taking place in an ordinary vacuum tube. But there is, in the first place, no good evidence that ordinary inactive matter can be transformed by the radiations of radioactive substances;⁴ and consequently, in view of the great energy of the α particles, there is reason for supposing that the swiftest ions in a vacuum tube are equally incapable of producing disintegration of atoms (or rather, according to recent views, disintegration of nuclei; the resultant positive charge upon which determines the chemical properties of atoms⁵)—unless, perhaps, there were present in the tube enormous differences of potential. Nevertheless, in an experiment by Sir W. Ramsay,⁶ evidence is given which suggests an inter-relationship between the elements helium, neon and oxygen.

Certain experiments performed by the writer upon the conduction of electricity at contacts of dissimilar solids⁷ show that, however carefully a metal may be cleaned in air, or in pure electrolytic oxygen, a surface film remains, sufficient to give electrical properties to such a surface, markedly different from those obtaining upon a surface that is cleaned mechanically in vacuo, or in pure electrolytic hydrogen. This being the case, it is seen that all electrodes hitherto employed in the production of rare gases have had a layer of oxide on the surface—traces of which must have remained until all the original surface had been removed by the action of the discharge.

In view of this fact it seems desirable that a tube be constructed, with electrodes similar to those used by Winchester⁸ (which were found to liberate the gases rapidly); it being possible to clean these electrodes on all sides,

³ J. N. Collie, *Roy. Soc., Proc., Ser. A*, 90, pp. 554-56, August 1, 1914.

mechanically, in vacuo; the apparatus, moreover, occupying but a small volume. The writer ventures to suggest the apparatus described below as being one which embodies the above essentials; the electrodes being substantially the same as those used by Winchester, which were in the form of circular loops of 2 mm. wire, 7 cm. in circumference, and 1 mm. apart.

Referring to Fig. 1, the electrodes are two straight parallel aluminium rods R_1 , R_2 , 2 or 3 mm. in diameter, and 8 cm. long. They are fastened to the glass tube T_1 by being bent around the ends of this tube, shown clearly in the horizontal section, Fig. 2.

and R_2 in turn by means of another strong electromagnet, M_2 —the cutting stroke being in the direction of the arrow. This operation scrapes but one side of each rod, R_1 , R_2 . To scrape the other two sides, A must be turned through 180° , which is accomplished by turning M_1 , M_2 through this angle. After the rods have been cleaned, A , L , C is moved into the tube T_1 , out of the way. It will be noticed that the apparatus is, essentially, a "spoke shave" in vacuo.

By using the above tube after the electrodes have been cleaned in pure (electrolytic) oxygen, it should be possible to demonstrate conclusively the transference of oxygen into

This tube, T_1 , is held in a larger tube, T_2 , by springs S_1 and S_2 (wires), the ends of which fit into dents in the glass tubes T_1 and T_2 . Leading-in wires w_1 and w_2 , attached to the ends of R_1 and R_2 , respectively, are sealed into the two side tubes t_1 and t_2 , Fig. 1; said side tubes connecting with a pump and a spectroscopic tube of the usual type.

A cutter, C , of hardened steel is attached by a flexible brass rod, L , to an armature, A . The cutting edge, K , Fig. 3, is semi-circular, to fit the rods R_1 and R_2 . The armature A has small brass rollers at the corners, to prevent scratching the inside of T_1 , and can be moved back and forth within this tube by means of electromagnets, M_1 and M_2 .

While the armature, A , is being moved in the tube, the cutter, C , is pressed against R_1 ,

helium and neon, if such indeed exist. On the other hand, if (as seems more likely) the helium and neon which appear in vacuum tubes have previously been occluded by the metal from the atmosphere, it should be possible, by means of the apparatus, to study the rates of, and the conditions governing, such absorption.

It is by no means certain, however, that the action in question consists simply in the liberation of absorbed gases, for Sir J. J. Thomson* has discovered evidence of a genuine production of helium and X_1 from elements (lead) and chemical compounds (salts of sodium and potassium) which suggests an actual atomic change, if not a genuine disintegration. The

* Sir J. J. Thomson, Roy. Soc., Proc., Ser. A, 89, pp. 1-20, August 1, 1913.

whole problem is very complicated, and it is the writer's purpose merely to call attention to the importance of surface conditions in the production of the rare gases.

ROBERT H. GODDARD

CLARK COLLEGE

THE FUNDAMENTAL EQUATION OF MECHANICS

MR. KENT, in his recent communication, invites expressions of opinion from Professor Huntington and myself regarding his method of explaining the principles of dynamics. My own view is that Mr. Kent's explanation of the effect of a constant force in giving motion to a free body initially at rest is entirely sound. It is, in fact, substantially the explanation I have long used in the classroom as a first step in establishing the fundamental equation of motion. Perhaps it is permissible to quote from my text-book on "Theoretical Mechanics," first published fifteen years ago:

If a force of constant magnitude and direction acts, for a certain interval of time, upon a body initially at rest, the body will have at the end of the interval a velocity whose direction is that of the force, and whose magnitude is proportional directly to the force and to the duration of the interval, and inversely to the mass of the body.

Since mass has already been defined as quantity of matter, this statement is seen to be identical in meaning with Mr. Kent's statement that "the velocity varies directly as the time and as the force, and inversely as the quantity of matter."

Mr. Kent's equation $V = KFT/W$ is entirely satisfactory and sufficient so long as our study is confined to the case in which a force whose direction and magnitude remain constant acts upon a body otherwise free and initially at rest. This is, however, a very exceptional case. The fundamental principle in its generality can be expressed only by introducing the notion of *instantaneous rate of change of velocity*, i. e., acceleration.* When this is done Mr. Kent's statement quoted above must be replaced by the statement that "the acceleration varies directly as the force and inversely as the quantity of matter," while his equation $V = KFT/W$ is superseded by the more general one $a = KF/W$. This is

identical with equation (5) of my former communication,¹ except that quantity of matter is there represented by m instead of W .

To pass from the equation

$$\text{acceleration} = K \times \frac{\text{quantity of matter}}{\text{force}} \quad (1)$$

to the equation

$$\text{acceleration} = \frac{\text{quantity of matter}}{\text{force}} \quad (2)$$

of course requires that units should be defined so that unit force acting on unit quantity of matter causes unit acceleration. Mr. Kent regards this as an objection to equation (2). If the objection is valid a similar one seems to apply to his own procedure. His equation

$$V = 32.1740 \frac{FT}{W}$$

is true only because his unit force is defined as the force which would give a pound of matter an acceleration of 32.1740 ft./sec.² The statement that the accurate value $K = 32.1740$ is found as the result of "the most refined experiments, involving precise measurements of both F and W , and of S , the distance traversed during the time T , from which V is determined" is quite misleading. The stated value of K is not based upon any refined measurements of the character described, but upon a purely ideal definition of the unit force; just as the value $K = 1$ results from a different ideal definition.

If there is any reason for preferring the set of units which makes $K = 32.1740$ to that which makes $K = 1$ in equation (1), it is not because the former is any more easily understood than the latter. "The force which, acting upon a pound of matter, would cause an acceleration of 32.1740 ft./sec.²" is the same kind of a definition as "the force which, acting upon a pound of matter, would cause an acceleration of 1 ft./sec.²" It is true that the former of the two units of force thus defined

¹ SCIENCE, April 23, 1915, p. 609. It is well known that Mr. Kent objects to the use of the word mass for quantity of matter; my present object is to make my meaning clear rather than to invite an unprofitable discussion over a purely verbal question.

has nearly the value of that used in the "ordinary English system," and this may be regarded as an advantage.² The unit in "ordinary" use, however, is not and never will be the exact "standard" pound, because for almost all practical purposes the refinement of distinguishing between "local" and "standard" gravity-pull is of no importance. For precise work there appears to be absolutely no choice between the system which makes $K=32.1740$ and that which makes $K=1$ except that the latter simplifies the fundamental equation and all equations depending upon it.

Mr. Kent thinks the C.G.S. system "should not be inflicted on young students" because it is "only used in higher physical theory." The great majority of those who study mechanics are preparing for the profession of engineering. In view of the fact that in a large and increasingly important part of the present-day field of engineering—applied electricity—the units employed are based upon the C.G.S. system, it is difficult to assent to the view expressed by Mr. Kent on this point.

L. M. HOSKINS

STANFORD UNIVERSITY,
March 29, 1915

CONDITIONS AT THE UNIVERSITY OF UTAH

TO THE EDITOR OF SCIENCE: In view of the fact that seventeen members of the faculty of the University of Utah have resigned their positions on the ground that it seemed to them "impossible to retain their self-respect and remain in the university," the council of the American Association of University Professors has authorized the appointment of a committee of inquiry to report upon the case. At the request of the president, the secretary of the

association recently spent four days in Salt Lake City investigating the situation in the university and collecting evidence to be laid before the committee. The special purposes and scope of the investigation are indicated in the extract from the letter addressed by the secretary of the association to the president of the university, which was printed in the issue of SCIENCE for last week.

The report of the committee of inquiry will be prepared and published at as early a date as is practicable. It is the purpose of the committee to present all the pertinent facts so fully in its report that university teachers may judge for themselves as to the administrative methods, and the conditions of professional service, in the university. We make this statement in order that any one who is considering either the acceptance of a position in the university or the recommending of others for such a position, may look forward to a full knowledge of the situation in the near future, and may postpone immediate action in case he deems such knowledge advisable before reaching a final decision.

JOHN DEWEY,

President of the American Association of University Professors,

A. O. LOVEJOY,

Secretary of the American Association of University Professors,

EDWIN R. A. SELIGMAN,

Chairman of the Committee of Inquiry

April 30, 1915

UNNATURAL HISTORY

TO THE EDITOR OF SCIENCE: I am sure your readers will be interested and instructed, and the monotony of their daily grind relieved, by the following information regarding hitherto unsuspected details in the life history of the kangaroo. These facts were given out by a university student in response to the question: "Explain how the young kangaroo obtains its nourishment."

"Immediately after birth they are swallowed by the mother and finally lodged directly over the breasts, the teats being directed inwards.

² The same advantage may be retained with the simpler equation (2) if we permit quantity of matter to be expressed in terms of a unit other than the pound. Why the reduction of quantity of matter from pounds to units 32.1740 times as great as the pound should be regarded as more puzzling than the reduction from pounds to tons on the reduction of a length from inches to feet, is something I have never been able to comprehend.

Here in their mother's heart the young marcupials are nourished for some time, when they are expelled from the mother fully developed and ready to begin life."

C. O. NUTTING

SCIENTIFIC BOOKS

Infection and Resistance. By PROFESSOR HANS ZINSSER, Professor of Bacteriology at the College of Physicians and Surgeons, Columbia University, New York City. The Macmillan Company. 1914. Pp. 546. Illustrated. \$3.50.

This work is conspicuously the most thorough and modern original treatment of the subject of infection and immunity that we have in the English language. The author's own work in the field of immunology, citations to which are frequently made in the text, makes the book authoritative.

We find in the book an exhaustive and impartial analysis of the enormous accumulation of recent work in this field with a wealth of references to original sources given at the bottom of the pages. The survey of the subject is complete, and yet each chapter is a unit in itself, making the book a convenient reference in which to gain a knowledge of any one phase of immunity. This unit arrangement of the chapters has necessitated some repetition, but not to an extent to become boring.

The text is not intended to be elementary or summary and can not be recommended for the average reader or undergraduate student. It can be most cordially recommended to practitioners, teachers, laboratory workers and especially as a text for medical students for whom it is primarily intended.

Starting with the general problem of Virulence, the author discusses successively the Bacterial Poisons, Natural and Acquired Immunity, Antitoxins, Cytolysis, Complement and Diagnosis, Agglutination, Precipitation, Phagocytosis (four chapters), Anaphylaxis (three chapters), Therapeutic Immunization, and a chapter on Abderhalden's Work on Protective Ferments. Dr. Stewart W. Young has been invited to write a concluding chapter on Colloids, which gives a comprehensive idea

of the nature of this state of matter, and the relation of colloids to biological problems.

The chapter on Therapeutic Immunization in Man might be criticized on account of its brevity in contrast to the rest of the book. It seems to the reviewer as though it could be made more effective even in the space allotted by the introduction of more data to show the efficacy of our marvelous advances in immunology.

C. M. HILLIARD

The Differentiation and Specificity of Starches in relation to Genera, Species, etc. Stereochemistry applied to Protoplasmic Processes and Products, and as a Strictly Scientific Basis for the Classification of Plants and Animals. By EDWARD TYSON REICHERT, M.D., Professor of Physiology in the University of Pennsylvania, Research Associate of the Carnegie Institution of Washington. In two parts. Published by the Carnegie Institution of Washington, Washington, D. C. 1913. Pp. 900, plates 102.

The author intends that the present memoir on starches shall have a relation to the memoir on hemoglobins worked out by Reichert and Brown and reviewed in SCIENCE (January 27, 1911). If there is a relationship between these two memoirs it is rather in what Dr. Reichert has attempted to perform than in what he has succeeded in accomplishing. The two memoirs are so different that a comparison of them is well-nigh impossible. In the one, we almost see the master and in the other the novice. The memoir on hemoglobins represents a painstaking research and is an important contribution to biology. The memoir on starches, in its present form, is hardly worthy to be classed as research, particularly in view of the splendid monograph of Naegeli which has been reputed to be among the greatest investigations of the last century. In the work on hemoglobins, through the cooperation of Dr. Brown, the exact methods of physical crystallography have been employed and it is to be expected that in the hands of different investigators confirmatory results will be obtained in the examination of the crystals of the various hemoglobins. In the present memoir on

starches, Dr. Reichert has replaced exact quantitative methods by those which under certain conditions might have a confirmatory value, but certainly are of no specific importance, as will be shown later, so that independent investigators may be able to confirm his observations and distinguish one species or genera from another. It is only necessary to read carefully a work like that of Solereder on the "Systematic Anatomy of the Dicotyledons" to appreciate the nature of the task that confronts an investigator who attempts to solve a fundamental problem such as Dr. Reichert has attempted.

Before critically examining the work it may be desirable to mention the contents of these two large volumes. Nearly 800 pages are devoted to a résumé of the important monographs and some of the important papers on the starches. The best part of this portion of the work is the translation from Naegeli's monograph on "Die Stärkekörner," giving his classification of some 1,200 starches. This comprises nearly 100 pages. Any review of the literature on starch must be unsatisfactory, as it is likely to be inadequate, and this is especially true of the summary by Dr. Reichert. It would have been far better in a memoir like this had Dr. Reichert placed in chronological order the literature which he cited so that it might be consulted or referred to by the student and the investigator, particularly if he intended this to be a work of reference on starches.

In Chapter VI. we find a discussion of some of the methods that the author considers might be employed in an investigation of this character and which involved the study of over 800 starches, which he isolated from as many different plants. He employed essentially six different methods: (1) Histological method, involving the study of the form, markings and size of grains. (2) Polariscopic properties, i. e., reactions using polarized light both with and without selenite. (3) Iodine reaction, using 0.125 per cent. and 0.25 per cent. of Lugol's solution. (4) Action with aniline dyes, using gentian violet and safranin, using 5 c.c. of a solution containing 0.05 per cent. of

aniline dye. (5) Temperature of gelatinization, which was determined with a specially constructed water bath, and in which was placed test tubes containing a small quantity of starch with 10 c.c. of water. (6) Several swelling reagents were used, viz., chloralhydrate-iodine solution, chromic acid in the form of a 25-per-cent. solution; ferric-chloride solution consisting of equal parts of a saturated solution in water, and Purdy's solution, which was made up of equal parts of the standard solution and water.

In the preparation of the starches, the material was comminuted, mixed with water, strained through cheese cloth, centrifugalized and washed with water and re-centrifugalized to remove as much impurity as possible.

The various starches were photographed both with and without polarized light. Some of these photographs are very excellent and in some instances may be of some scientific value. For the most part, however, unless photographs of starches are supplemented with drawings they lose much of their interest and significance.

Great stress is laid by the author on the different reaction intensities of the several reagents on any given starch and these have been set forth graphically in the form of curves with a view of affording a clear presentation of the quantitative reaction peculiarities of the starches and permit of comparison between them. "In the construction of the charts the abscissas have been used to express the degree of polarization (*P*), the intensity of the iodine reaction (*I*), the intensity of the gentian violet reaction (*GV*), the intensity of the safranin reaction (*S*), the temperature of gelatinization (*T*), the time-reaction of chloral hydrate-iodine (*CHI*), the time-reaction of chromic acid (*CA*), the time-reaction of pyrogallie acid (*PA*), the time-reaction of ferric chloride (*FC*), and the time-reaction of Purdy's solution (*PS*). The letter or letters as above given in parentheses each lie at the head of a special column or ordinate, and indicate the agent, while those of the abscissas give the values of the reactions. The letters of the column under *P* indicate, respectively, very

high, high, fair, low and very low; and under I, GV and S, very dark, dark, fair, light and very light."

The procedure in the examination of the several starches by Dr. Reichert is as follows: The temperature of gelatinization and intensity of color of aniline dyes was determined by placing a small amount of starch in a test tube containing in the one case 10 c.c. or an excess of water and in the other case 5 c.c. or an excess of solution of the dye. In using iodine solution he does not say how much starch was employed, but merely states that "the starch was placed on a slide and one or two or more drops of the iodine solution added, the whole covered with a cover slip." In the use of swelling reagents we read that "a small amount of starch is placed on a slide, several drops of the reagent added, a cover glass put on, and the progress of events examined under the microscope." Granting that there is a certain variation to a limited extent in the shade and intensity of color produced by certain reagents with some of the starches,¹ these differences will only hold when definite quantities of starch and definite quantities of reagent are used. From the statements in the foregoing paragraph showing the method of making microscopic mounts, it is apparent that Dr. Reichert did not bear in mind this fundamental fact as he did not use definite quantities of starch with definite quantities of reagent. One illustration is sufficient to show the weakness of his technique and the untrustworthiness of his results. Let the worker make four mounts, using varying quantities of starch and iodine solutions as follows: (1) 0.008 gm. of starch and 1 drop of iodine solution; (2) 0.006 gm. of starch and 1 drop of iodine solution; (3) 0.003 gm. of starch and 2 drops of iodine solution; (4) 0.006 gm. of starch and 2 drops of iodine solution. If a solution be employed containing 0.25 per cent. of Lugol's solution as adopted by Dr. Reichert, the intensity of color will not be as pronounced as if a reagent containing 0.50 per cent. of Lugol's solution be used. In any case the reactions in the several mounts will show con-

siderable variation, a more intense blue coloration being usually discernible in mounts containing 0.003 gm. of starch and 2 drops of reagent and weakest in mounts containing 0.006 gm. of starch and 1 drop of reagent. Nearly equally as striking differences will be obtained when using varying quantities of starch with two or more drops of the swelling reagents employed by Dr. Reichert. A more noticeable and complete swelling being produced when less starch (0.006 gm.) is employed, with an excess of reagent (4 drops), and a partial or incomplete gelatinization always being observable when an excess of starch (0.012 gm.) are used with a minimum quantity (2 drops) of the swelling agent. When we consider the nature of starch these varying results are to be expected unless a quantitative relation be borne in mind between the amount of starch and the number of drops of reagent employed.

The method employed by Dr. Reichert in determining the temperature of gelatinization and of coloration with aniline dyes might have been applied to the use of other reagents. In the designation of intensity of color reaction with aniline dyes and iodine, Dr. Reichert was unfortunate in adopting an arbitrary scale of very dark, dark, fair, light and very light, as hardly any two observers would agree as to whether a color was dark or fair, etc. It would have been a great deal better had there been an accurate color scale embodied in the publication so that Dr. Reichert's work could be confirmed.

In view of these serious criticisms involving a crude technique and one which is liable to give discordant results in the hands of different investigators we must conclude that Reichert's work has added practically nothing to the interesting question of stereoisomerism of the starches, nor can it be considered as a serious contribution to our knowledge of the specificity of starches in relation to genera, species, etc. Apparently it will be very difficult for any one very soon to add anything of a fundamental character or in a comprehensive way to the study of starches and that can be at all compared to the monumental work on "Die

¹ Bot. Gaz., October, 1905.

Stärkekörner" written by Naegeli in 1874. This does not mean that there are not many interesting and important problems connected with the study of the starch grain, but the solution of these can be accomplished only at the hands of the experienced specialist engaged in research or under the direction of a master mind.

HENRY KRAEMER

PHILADELPHIA COLLEGE OF PHARMACY,

SPECIAL ARTICLES

THE OSMOTIC PROPERTIES OF DIFFERENT KINDS OF MUSCLE

In two recent articles¹ I have pointed out that the osmotic properties² of the smooth and striated muscle of the frog and of the clam's adductor muscle were strikingly different. Loeb suggests³ that the differences observed by me might be due to the fact that "the smooth muscle of the stomach . . . can not be obtained in as natural a condition as . . . striped muscle . . ." Still more recently, in an article published from Loeb's laboratory, v. Körösy⁴ has enlarged upon Loeb's suggestion and has described some experiments purporting to uphold it.

The reasons for thinking that the differences in the osmotic behavior of the three types of muscle mentioned above can not be due to any difference in the manner of their preparation seem to me very cogent; they have already been largely given in my articles dealing with the subject. But it has not previously been possible to give them completely or to bring them together into one place, and, in view of the suggestions of Loeb and v. Körösy, it seems worth while to do this now.

The first difficulty which one meets in com-

paring the reactions of smooth and striated muscle is that cutting across the fibers or removing the "natural surface" does not have the same effect on the two tissues. Striated muscle goes almost immediately into rigor in the neighborhood of a cut across its fibers. This condition is accompanied by acid formation,⁵ by swelling, and by the loss of irritability and of the characteristic osmotic properties of the tissue; it spreads gradually from the point of injury to other parts. Cutting across the fibers of smooth muscle causes a contraction which is soon followed by relaxation; there is no tendency toward acid formation, swelling or loss of irritability either in the neighborhood of the cut or in any other portion of the tissue. These facts, which are ignored by Loeb and v. Körösy, are very significant; they suggest at the outset, what is confirmed by all my subsequent work, that the fibers of striated muscle are surrounded by characteristic semi-permeable surfaces, injury to which produces profound changes in the tissue; and that no such surfaces exist in the case of smooth muscle. They are incompatible with the view that the osmotic properties of the tissues are alike. Finally, they show that my preparations of smooth muscle, in spite of the fact that their fibers have been cut, are more nearly comparable to uninjured than to injured preparations of striated muscle.

But one need not stop here. The rigor, etc., produced in the neighborhood of a cut across the fibers of striated muscle spreads only gradually from the injured to the uninjured regions; hence, if the injured area be proportionally small, the preparation will react osmotically for the first hour or so very nearly like an uninjured muscle. If a frog's sartorius be cut across its middle, either half of the muscle will have about the same proportions of "natural surface" and "unnatural surface" as the preparations of frog's stomach muscle used in my experiments. Such a cut sartorius reacts for the first hour in all respects very much like an uninjured sartorius. The strikingly different osmotic reactions characteristic of smooth muscle showed themselves

⁵ Fletcher and Hopkins, *The Journal of Physiology*, Vol. 35, pp. 261 et seq., 1907.

¹ Meigs, *The Journal of Experimental Zoology*, Vol. 13, p. 497, 1913; *The Journal of Biological Chemistry*, Vol. 17, p. 81, 1914.

² By "osmotic properties" I mean those properties of the tissues which determine the characteristic changes of weight undergone by them when immersed in various solutions.

³ Loeb, *SCIENCE*, N. S., Vol. 37, p. 430, 1913.

⁴ V. Körösy, *Zeitschrift für physiologische Chemie*, Vol. 93, pp. 171 et seq., 1914.

in my preparations long before the end of the first hour.

Further, the effects of cutting across the fibers or of exposing an "unnatural surface" in smooth muscle may be studied experimentally by comparing the reactions of preparations which have been cut in many places with those of others which have been cut as little as possible. Such experiments show that cutting has no perceptible effect after the first few minutes; for the first few minutes it produces a very slight tendency for the preparation to lose fluid. Examination of the differences in the osmotic reactions of smooth and striated muscle under different circumstances shows that these differences can not be explained as the result either of this or of any other conceivable effect of injury. Smooth muscle, for instance, swells more rapidly than striated muscle in Ringer's solution, but less rapidly in half-strength Ringer; it would be a very extraordinary hypothesis that these opposite differences were both the effects of injury. Still less can the swelling of smooth muscle in solutions of non-electrolytes and the peculiar changes of weight undergone by it in double-strength and half-strength Ringer solution be explained as the result of injury by any one who will take the trouble to make a careful study of these phenomena.

In order to obtain a preparation of striated muscle comparable to my preparations of smooth muscle v. Körösy pared off the surface layers of a frog's gastrocnemius with a razor and used the core which was left. This is, to say the least, a severe test. The gastrocnemius is for the most part composed of short fibers which run diagonally across it and end in the fascia covering its surface. The procedure adopted by v. Körösy would therefore give a surface largely or entirely composed of the cut ends of the muscle fibers. My preparations of stomach muscle were covered on one side by the serosa and on the other by a part of the connective tissue which lies between the muscular and mucous coats of the stomach; these two surfaces made up about nine tenths that of the whole preparation, and were certainly as "natural" as that which is left

covering a striated muscle after it is torn away from the skin and from the neighboring muscles.

V. Körösy tried only one experiment which bears on the osmotic differences between the smooth and striated muscle of the frog. He immersed his muscle core in 0.23 M saccharose solution and found that it gained weight fairly rapidly. It is to be presumed that lactic acid was being rapidly produced over the whole surface of v. Körösy's preparation,⁶ and it is not surprising, therefore, that it should gain weight in either 0.23 M saccharose solution or in any other solution nearly isosmotic with frog's blood. But, in view of the considerations given above, it can hardly be supposed that this experiment shows that the osmotic properties of smooth and striated muscle are alike.

V. Körösy also immersed his gastrocnemius cores in various hypertonic NaCl solutions, and found that they lost weight in the early stages of their immersion.⁷ These results are to be compared with mine on the adductor muscle of the clam, which had already begun to gain weight after five minutes' immersion in a strongly hypertonic NaCl solution.⁸ My preparation was certainly not any more injured than v. Körösy's in this case, yet under comparable experimental conditions it gained weight and his lost. I do not understand, therefore, why he thinks that his experiments with the gastrocnemius core indicate that the osmotic properties of the various kinds of muscle under consideration are alike, nor do I understand his remark on page 173, which I take to mean that we need information about the changes of weight undergone by clam's muscle in the early stages of its immersion in hypertonic solutions. We already have detailed information on this point.⁹

⁶ Fletcher and Hopkins, *The Journal of Physiology*, Vol. 35, pp. 261 *et seq.*, 1907; Laquer, *Zeitschrift für physiologische Chemie*, Vol. 92, p. 69, 1914.

⁷ *Loc. cit.*, pp. 170 and 171 and Table 11.

⁸ Meigs, *The Journal of Biological Chemistry*, Vol. 17, Experiment 17, p. 97, 1914.

⁹ Meigs, *loc. cit.*, Experiments 3 and 17, pp. 95 and 97.

With regard to v. Kőrösy's supposition (pp. 172 and 173) that my preparations of frog's stomach muscle were contaminated with acid, I can only say that it is incorrect. I took particular pains to avoid contamination of the muscle with the stomach contents; the preparations were decidedly alkaline to litmus at the beginnings of the experiments and remained so for at least twenty-four hours.

It seems to me that any further attempt to show that the smooth and striated muscle of the frog and the adductor muscle of the clam are all equally subject to the "law of Avogadro-van't Hoff" should be based on experiments on all three kinds of muscle and on careful consideration of the data already at hand, rather than on experiments confined to striated muscle and backed up only by experimentally unfounded suppositions.

EDWARD B. MEIGS

THE WISTAR INSTITUTE OF
ANATOMY AND BIOLOGY

ON THE TAXONOMY OF THE PROCYONIDÆ

WITHIN recent time I have, through the courtesy of the United States National Museum and the Academy of Natural Sciences of Philadelphia, enjoyed the opportunity of making a comparative study of the skeletons of the procyonine mammals of America, and that of the panda of the Old World. These researches have resulted in the production of a memoir setting forth in full complete and comparative accounts of the osteology of all these species and genera, as well as thorough studies of their several dental armatures. This memoir carries with it thirteen quarto plates, upon which are to be found eighty-seven photographic figures, giving all the skulls and many other bones of the skeletons of these procyonine species, together with the skull of *Ailurus fulgens*. In all cases the figures are given natural size.

As there is usually some little delay in the publication of memoirs of this class, I have thought best to publish here an advance abstract, setting forth some of my findings with respect to this group in the matter of

their classification. All descriptive details, as well as the large number of osteological figures of the Procyonidæ, will be available to mammalogists later on—that is, at such time as I can arrange for the publication of this work in its entirety.

As to the panda, I have said: "Judging from the characters presented on the part of its teeth; its skull, with the presence of the alisphenoid canal, and its Asiatic habitat, it is clear that *Ailurus fulgens*, the panda, is but remotely related to such forms as the raccoons, the coatis, or the kinkajous. Wherever it belongs, it does *not* belong in there. Having studied only the teeth and skull of a single individual, I am not prepared to say much in regard to its affinities; but I am of the opinion that it belongs, as a superfamily, Ailuroidæ, between the bears and the procyonine forms. Possibly *Ailuropus* may be the connecting type here—that is, with the ursine series.

Apart from their special character differences, which have been given in detail above, the dental formulæ agree in *Bassariscus*, *Nasua* and *Bassaricyon*, while in *Potos* the formula is different. This fact alone is sufficient evidence to convince a mammalogist that the Kinkajous are, at least to this extent, more or less removed from the more typical raccoon group. In *Bassaricyon*, although the formula is the same as in a raccoon, the teeth differ markedly in their special characters. Especially is this the case with respect to their morphology and extremely feeble tuberculation.

In not a few particulars its cranium and mandible agree with that part of the skeleton in *Bassariscus*, though the curvature of the superior cranial line is more as we find it in *Procyon*—that is, in *Bassaricyon* it is not so flat and straight as it is in the ring-tailed *bassarica*.

Not having examined the entire skeleton, my opinion is given tentatively in so far as the taxonomical position of *Bassaricyon* is concerned; but with the morphology of its teeth and skull before us, it is clear that it possesses characters common to both the true

raccoons as well as to *Bassariscus*, and therefore belongs in some subdivisional group by itself. This is likewise true of *Nasua*, for, although the morphology and characters of its skull, axial skeleton and limbs are procyonine, it nevertheless departs very decidedly from the true raccoons in not a few of its osteological characters. This is seen in the elongate form of the skull in *Nasua* with its relatively smaller bullae; the mesial foramen between the anterior palatine foramina; the upturned nasals, but more particularly the great differences to be found in the long bones of its skeleton; their proportional lengths and their characters, as well as the difference in form of the scapula and pelvis. These constant differences in the skeleton among *Bassariscus*, *Procyon* and *Nasua* are supergeneric and must be so considered.

Coming to *Potos*, we not only find the radical difference in the dental armature as compared with all the other genera; but its skull, although exhibiting certain general procyonine characters, is, in its form, entirely different from the skull of *Procyon*, or of *Nasua*, or the *bassariscus*, or of *Bassaricyon*. The skull of a kinkajou is as short as the skull in a domestic cat; the mastoid process is entirely aborted; the paroccipital stands away from the bulla on the same side; tympanics short; frontal sinuses extremely small; and in the mandible the complete coossification of the horizontal rami at the symphysis, with the lower border of the bone concave. There are likewise numerous differences in the axial skeleton which have been fully enumerated above. In short, *Potos*, with its short skull; prehensile tail; different vertebral column; and other departures in its skeleton from the more closely related genera noted above, belongs strictly in a group by itself—that is, the several species do, and, while evidently procyonine in its characters and relationships, it is nevertheless well removed from the more typical raccoons, and the further we study its habits and anatomy, the more evident does this fact become.

In short, this group of mammals constitutes a superfamily PROCYONOIDEA, divisible

into two families—the Procyonidae and the Potosidae, with the former family divided into three subfamilies, Bassarisinae, Bassaricyoninae and Nasuinae, thus:

PROCYONOIDEA	Superfamily	Families	Subfamilies
	{	Procyonidae	{ Bassarisinae Bassaricyoninae
		Potosidae	{ Nasuinae Potosinae

and this I believe to be their true relationships in nature.

R. W. SHUFELDT

WASHINGTON, D. C.,
December 24, 1914

THE NATIONAL ACADEMY OF SCIENCES

THE sessions of the annual meeting of the academy were held in the Oak Room of the Raleigh Hotel and in the United States National Museum, Washington, D. C., on April 19, 20 and 21, 1915.

Sixty-one members were present, as follows: Abel, Becker, Bell, Boltwood, Britton, Bumstead, Cattell, Chamberlin, Chittenden, Clark (W. B.), Clarke (F. W.), Clarke (J. M.), Conklin, Coulter, Cross, Dall, Davenport, Davis, Day, Donaldson, Fewkes, Frost, Hague, Hale, Harper, Harrison, Hayford, Hillebrand, Holmes, Howell, Jennings, Loeb, Mull, Meltzer, Mendel, Merriam, Michelson, Moore, Morgan, Morley, Nichols (E. L.), Noyes (A. A.), Noyes (W. A.), Osborn (H. F.), Osborne (T. B.), Parker, Pickering, Pirsson, Ransome, Reid, Rensen, Schuchert, Scott, Smith (Erwin F.), Walcott, Webster, Welch, Wheeler, White, Wood (R. W.), Woodward.

The following scientific program was carried out in full:

"Localization of the Hereditary Material in Germ Cells," by Thomas H. Morgan.

Problems of Nutrition and Growth:

"Stimulation of Growth," by Jacques Loeb.

"Specific Chemical Aspects of Growth," by Lafayette B. Mendel.

"Basal Metabolism during the Period of Growth," by Eugene F. Du Bois, medical director, Russell Sage Institute of Pathology (by invitation of the Program Committee).

"Retention in the Circulation of Injected Dextrose in Depancreatized Animals and the Effect of an Intravenous Injection of an Emulsion of Pancreas upon this Retention," by I. S. Kleiner and S. J. Meltzer.

"The Electrical Photometry of Stars," by Joel Stebbins, Draper Medallist.

"A Vortex Hypothesis of Sun Spots," by George E. Hale.

"The Spectroscopic Binary, Mu Orionis," by Edwin B. Frost.

"One-Dimensional Gases and the Experimental Determination of the Law of Reflection for Gas Molecules," by Robert W. Wood.

"The Relations Between Resonance and Absorption Spectra," by Robert W. Wood.

"On the Polarized Fluorescence of Ammonio-Uranyl Chloride," by Edward L. Nichols and H. L. Howes.

"Atomism in Modern Physics," by Robert A. Millikan (by invitation of the Program Committee).

"Problems Associated with the Origin of Coral Reefs, Suggested by a Shaler Memorial Study of the Reefs of Fiji, New Caledonia, Loyalty Islands, New Hebrides, Queensland and the Society Islands, in 1914," by William Morris Davis.

"Inorganic Constituents of Marine Invertebrates," by F. W. Clarke.

"Amphibia and Reptilia of the American Carboniferous," by Roy L. Moodie (introduced by H. F. Osborn).

"Human Races of the Old Stone Age of Europe, the Geologic Time of their Appearance, their Racial and Anatomical Characters," by Henry Fairfield Osborn and J. Howard McGregor.

"On the Fossil Algae of the Petroleum-yielding Shales of the Green River Formation," by Charles A. Davis, geologist, Bureau of Mines (by invitation of the Program Committee).

"The Forests of Porto Rico," by Nathaniel L. Britton.

"Pictures on Prehistoric Pottery from the Mimbre Valley in New Mexico and their Relation to those of Casas Grandes," by J. Walter Fewkes.

"Inheritance of Temperament," by Charles B. Davenport.

"Inheritance of Huntington's Chorea," by Charles B. Davenport.

"The Fur Seal Herd of the Pribilof Islands," by George H. Parker, official representative of the academy upon the Special Commission appointed by the President of the United States to study and report upon the Alaskan Fur Seal during the summer of 1914.

"The Evolution of the Earth," by Thomas Chrowder Chamberlin, of the University of Chicago, William Ellery Hale lecturer.

The president announced that the preparation of biographical memoirs of deceased members had been assigned as follows:

Howditch, Henry P. Cannon, Walter B. Davidson, George Existing biography approved.

Gould, B. A. Comstock, George C. Mitchell, Henry Hayford, John F. Mitchell, Silas Wier Welch, William L. Chandler, Seth Carlo Elkin, William L. Peirce, Benjamin Osgood. Hall, E. H. Holden, Edw. Singleton. Campbell, W. W. Hill, George William Brown, E. W. Gill, Theodore Nicholas. Dall, William H. Minot, Charles Sedgwick. Donaldson, Henry H. Billings, John S. Garrison, Fielding H.

The president announced the death since the autumn meeting of one foreign associate:

Auwers, G. F. J. Arthur, January 24, 1915, elected 1883.

Reports of the President and Treasurer

The reports of the president¹ and treasurer² for 1914 as transmitted to the senate of the United States by the president of the academy were presented in their printed form and approved.

Report of the Home Secretary

THE PRESIDENT OF THE NATIONAL ACADEMY OF SCIENCES:

Sir: I have the honor to present the annual report of home secretary of the National Academy of Sciences for the year ending April 21, 1915.

The memoir of the National Academy of Sciences, Volume 12, Part 1, and bearing the title, "Monograph of the Bombycine Moths of North America," by A. S. Packard, edited by T. D. A. Cockerell, has been published and distributed to the members, foreign associates, institutions and reference libraries; Volume 12, Part 3, of the *Memoirs*, entitled "The Turquoise," by Joseph E. Pogue, has also been published and distributed to the members; Part 2 of this same volume entitled, "Variations and Ecological Distribution of the Snails of the Genus *Io*," by Charles C. Adams, has received final consideration, and is now waiting to be bound at the Government Printing Office; the memoir forming Volume 13, being "A Catalogue of the Meteorites of North America," by Oliver C. Farrington, only awaits press work and binding before it is issued.

The biographical memoirs of John Wesley Powell, Charles A. Schott and Miers Fisher Longstreth have been published. The publication of the memoir of J. Peter Lesley, by Dr. William M. Davis, has been approved by the committee on publication, and the biography of Henry Morton,

¹ Report of the National Academy of Sciences for the year 1914, pp. 11-56.

² *Idem*, pp. 57-83.

by Edward L. Nichols, has been printed and awaits the portrait.

Three members have died since the last annual meeting: Theodore Nicholas Gill, on September 25, 1914, elected in 1873; Charles Sedgwick Minot, on November 19, 1914, elected in 1897, and Henry Lord Wheeler, on October 30, 1914, elected in 1909.

Of our foreign associates, Eduard Suess died on April 26, 1914, elected in 1898; August Weismann, on November 5, 1914, elected in 1913; Hugo Kronecker, on June 6, 1914, elected in 1901; G. F. J. Arthur Auwers, on January 24, 1915, elected in 1883.

There are 134 active members on the membership list, 1 honorary member, and 43 foreign associates.

ARTHUR L. DAY,
Home Secretary

Report of the Directors of the Bache Fund

TO THE PRESIDENT OF THE NATIONAL ACADEMY OF SCIENCES:

Sir: The serious illness of Dr. Charles S. Minot, the chairman of the board of directors of the Bache Fund, made it difficult to carry on the work of the board for several months. His death in November last left a vacuum hard to fill, as he was most conscientious in the performance of his duties. After careful consideration the two remaining members of the board elected Professor Ross G. Harrison the third member and he accepted. In turn the board elected the undersigned chairman.

Since the last annual meeting of the academy the following appropriations have been made:

No. 182. W. C. Kendall, \$600. April 30, 1911. Toward the expenses of illustrations in color and incidental expenses in connection with part II. (Salmonidae), fishes of New England, to be published by the Boston Society of Natural History.

No. 183. C. G. Abbot, \$250. June 29, 1914. To complete and test on Mt. Wilson in California an apparatus consisting of a concave cylindric mirror of about 100 sq. ft. surface adapted to heat oil to circulate through a reservoir containing ovens and water pipes, and thereby to utilize solar radiation for cooking and for heating water for domestic purposes.

No. 184. P. W. Bridgman, \$500. September 14, 1914. To continue the work on high pressures, especially to investigate the phase changes brought about in various substances by very high pressure.

No. 185. Robert W. Hegner, \$160. December 26, 1914. To determine the visible changes that take place during the differentiation of the germ cells in the embryos of hermaphroditic animals, and to discover, if possible, the cause of these changes.

No. 186. J. Voutte, \$800. February 9, 1915. For the determination of parallaxes of southern stars by transits. The Bache Fund has heretofore granted \$1,000 for this research. It is conducted at the Royal Observatory, Cape of Good Hope, wholly at the expense of Mr. Voutte, except for these grants.

No. 187. H. H. Lane, \$500. April 14, 1915. To make a comparative study of the embryos and young of various mammals in order to determine, by physiological experimentation and morphological observations, the correlation between structure and function in the development of the special senses.

IRA REMSEN,
Chairman

April, 1915

Report of the Trustees of the Watson Fund

The will of the late James Craig Watson provided "for the promotion of astronomical science," but he expressed the wish that a medal should be given and that tables should be prepared of the motions of all the planets discovered by him. This last wish has now been carried out in a most satisfactory manner by Professor A. O. Leuschner, so that the income which has been used for this purpose during the last fourteen years is now available for the promotion of astronomical science in other directions.

The undersigned accordingly recommend the following votes:

Resolved, That the sum of five hundred dollars from the income of the Watson Fund be appropriated to Professor John A. Miller, director of the Sproul Observatory, for measuring plates already taken for the determination of stellar parallaxes.

Resolved, That the sum of three hundred dollars be appropriated from the income of the Watson Fund to Mr. John E. Mellish, to enable him to undertake observations at the Yerkes Observatory.

E. O. PICKERING, *Chairman*,
W. L. ELKIN,
EDWIN B. FROST

April 2, 1915

Report of the Committee on the Henry Draper Fund

The committee unanimously recommends to the academy that the following grants for research be approved:

Five hundred dollars to Dr. W. W. Campbell, director of the Lick Observatory, for the purchase and construction of spectrographs and other apparatus for use with the Crossley Reflector.

Two hundred and fifty dollars to Dr. S. A. Mitchell, director of the Leander McCormick Observatory, for the purchase of a machine for measuring astronomical photographs.

GEORGE E. HALE,
Chairman

Report of the Committee on the J. Lawrence Smith Fund

TO THE NATIONAL ACADEMY OF SCIENCES:

In regard to researches now in progress or lately completed which have received aid from this fund the committee reports as follows:

Grant No. 3. Edmund Otis Hovey, curator in geology and paleontology in the American Museum of Natural History, New York, received in 1910 a grant of \$400 in aid of the study of certain meteorites. Metallographic and chemical examinations are in progress. Dr. Hovey is at this time out of the country.

Grant No. 4. Professor C. C. Trowbridge, of the department of physics in Columbia University, received in 1910 a grant of \$400 in aid of his study of the luminous trains of meteors. The academy has also made further grants of \$250 in 1912, of \$250 in 1913, and of \$250 in 1914. The important work of collecting, verifying and tabulating records of observations of luminous trains has been diligently pursued. Lately, the collection and preparation for publication of drawings of luminous trains has been undertaken. In accordance with the vote of the academy in 1912, three payments have been made from this grant and it is expected that the fourth and last installment will be required during the current year.

Grant No. 5. Dr. George P. Merrill, curator in the department of geology in the United States National Museum, received a grant of \$200 in 1910, and of \$200 in 1911, to aid in the study of the occurrence of certain elements suspected to be present in small quantities in some meteorites. This work has been successfully completed, and the final report is ready for submission to the academy; the report contains a tabulation of all available trustworthy analyses of meteorites, and is accompanied by a special paper on the occurrence in meteorites of francolite or some allied phosphatic mineral in place of the apatite of terrestrial rocks.

The cash balance of income now available for grants is \$874.87, and the invested income is \$1,532.50.

EDWARD W. MORLEY,
Chairman

Professor S. A. Mitchell, University of Virginia, has applied for a grant of \$500 to aid in the computation of orbits of meteors. Dr. Charles P. Olivier, president of the American Meteor Society, has computed orbits from some nine thousand observations of meteor paths, and has some thousand observations awaiting reduction. He has published two important papers containing several hundred computed orbits. The committee recommend the grant of \$500 to Professor S. A. Mitchell, to aid in computations of orbits of meteors.

EDWARD W. MORLEY,
Chairman

The following motion was presented:

That the Committee on the J. Lawrence Smith Fund recommend that the meteorites remaining from the purchases by Dr. Merrill be deposited by the National Academy of Sciences in the United States National Museum.

Report of the Board of Directors of the Benjamin Apthorp Gould Fund

The income balance of the Gould Fund is now, in cash, four hundred and four dollars and sixty-four cents (\$404.64); in readily negotiable securities, four thousand and fifty-seven dollars and fifty cents (\$4,057.50), and in an unpaid grant to the *Astronomical Journal*, one thousand dollars (\$1,000).

F. B. MOULTON,
E. E. BARNARD

Report of the Directors of the Wolcott Gibbs Fund

The trustees of the Wolcott Gibbs Fund for Chemical Research have the honor to present their annual report to the National Academy of Sciences. Since the last report three grants have been made from the income of the Fund as follows:

III. One hundred dollars to Professor W. J. Hale, Ann Arbor, to pay for assistance in a research on derivatives of 2,3-diacetylpentadiene, voted May 15, 1914.

Professor Hale reports that he has prepared the cyclopentadienylpyridazine and the corresponding phenyl compound, and determined their composition. He hopes to finish the research before the summer vacation.

IV. Two hundred dollars to Professor W. H. Haskins, University of Chicago, for making a special potentiometer and galvanometer to study cobaltammines and ternary systems of fused salts. Voted November 25, 1914.

Professor Haskins reports that a beginning has been made on the work in spite of his severe sickness and the fact that the war has prevented him from obtaining part of the apparatus from Germany.

V. A second grant of one hundred dollars to Professor Mary E. Holmes, of Mount Holyoke College, for assistance in her work on the electrolytic determination of cadmium. Voted March 18, 1915.

Professor Holmes reports that she has purchased platinum electrodes of a new form, and with these has studied the deposition of cadmium and copper, so that she is now beginning to study the electrical separation of cadmium from other metals.

The unexpended income of the fund amounted on April first to \$111.99.

C. L. JACKSON,
Chairman

Report of the Committee on Solar Research

The committee begs to call the attention of the academy to the publication of Vol. IV. of the *Transactions of the International Union for Co-operation in Solar Research*, which contains the complete proceedings of the last meeting in Bonn, reports of the various committees, resolutions adopted by the Union, and several scientific papers on solar and stellar phenomena.

The four volumes of *Transactions* already published by the Solar Union may be obtained from Messrs. Longmans, Green & Company, Fourth Avenue and 30th Street, New York, at \$2.50 per volume.

GEORGE E. HALE,
Chairman

Recommendations from the Council

That the following bequest from Mrs. Mary Anna Palmer Draper be accepted.

Extract from the Will of Mrs. Mary Anna Palmer Draper, Page 7, Section 9 (Second Paragraph): "I give and bequeath to the National Academy of Sciences, Smithsonian Institution, Washington, D. C., the sum of twenty-five thousand dollars (\$25,000)."

Report of the Editorial Board of the Proceedings

The editorial board of the *Proceedings* reports to the academy that four numbers of the *Proceedings* have now been issued, containing sixty-seven original papers in addition to the report of the autumn meeting, notices of scientific memoirs, and announcements. These numbers have consisted of 258 pages, an average of 64 pages per number and of about four pages per article. The papers are distributed among different sciences as follows: mathematics, 11; astronomy, 11; physics, none; chemistry, 11; geology, 2; paleontology, 1; botany, 4; zoology (including genetics), 12; physiology, 8; pathology, none; anthropology, 5; psychology, 2. It will be noticed that the subjects of physics, of geology and paleontology, and of pathology, have been very inadequately represented; and the editorial board urges members of the academy in those fields to endeavor to remedy this situation.

An edition of 3,000 copies of these four numbers has been printed. Of this edition about 900 are to be sent abroad to the libraries of universities and other active research institutions upon a mailing list prepared with great care by the foreign secretary aided by members of the editorial board. Of this edition 1,200 copies have also

been distributed in this country by the home secretary to important libraries and to the thousand persons whose names are starred in Cattell's *American Men of Science*.

ARTHUR A. NOYES,
Chairman

Report of the Committee on the Collection of Historical Portraits, Manuscripts and Instruments

TO THE PRESIDENT AND MEMBERS OF THE NATIONAL ACADEMY OF SCIENCES:

Your committee on the collection of historical portraits, manuscripts and instruments, including instruments purchased at the expense of the trust funds which are no longer needed for the original purpose, begs to report as follows:

That the collection of portraits of the members of the academy has been brought together and arranged alphabetically.

That the foreign secretary has turned over the medal from the Groningen Academy celebrating its four hundredth anniversary.

That the following apparatus was presented by Mrs. Henry Draper and has been deposited in the United States National Museum:

- 1 slit.
- 1 spectrum photograph (broken).
- 1 liquid prism cell.
- 1 prism with 2-inch faces.
- 1 bundle—attempts of Henry Draper to rule gratings.
- 1 speculum metal ruled surface; 2-inch, square.
- 1 bunsen burner.
- 2 boxes, 12 photographs each.
- 1 box, 50 photographs.
- 1 box, 34 photographs.
- 1 box, 22 photographs.
- 1 box, 15 daguerreotypes.
- 1 box, 7 photographs.
- 13 Geissler tubes.

Election of Members of the Council

Mr. W. H. Howell and Mr. J. M. Coulter were chosen to succeed Mr. W. T. Councilman and Mr. R. S. Woodward.

Election of New Members

Henry Seely White, mathematician, Vassar College, Poughkeepsie, N. Y.

Charles Greeley Abbot, astrophysicist, Astrophysical Observatory, Smithsonian Institution, Washington, D. C.

Robert Andrews Millikan, physicist, University of Chicago, Chicago, Ill.

Alexander Smith, chemist, Columbia University, New York City.

Samuel Wendell Williston, paleontologist, University of Chicago, Chicago, Ill.

William Ernest Castle, zoologist, Harvard University, Cambridge, Mass.

Frank Rattray Lillie, zoologist, University of Chicago, Chicago, Ill.

Graham Lusk, physiologist, Cornell University Medical College, New York City.

Victor Clarence Vaughan, pathologist, University of Michigan, Ann Arbor, Michigan.

Granville Stanley Hall, psychologist, Clark University, Worcester, Mass.

An amendment to the constitution was adopted which permits the admission of 15 members annually in future.

ARTHUR L. DAY,
Home Secretary

NEW ORLEANS MEETING OF THE AMERICAN CHEMICAL SOCIETY

The fiftieth meeting of the American Chemical Society was held in New Orleans, Louisiana, March 31 to April 3, 1915. For the most part, the members reached New Orleans during the morning of March 31 and spent some hours in viewing the unique attractions of the city. At 4:30 P.M., two hundred and fifty members and guests boarded a steamer for a trip down the Mississippi River, the usual complimentary smoker being held on the boat. The smoker was one of unusual attractions, the long cabin of the boat being festooned with Spanish moss and laurel and various southern evergreens, making a very attractive scene. The evening was enlivened by music from two orchestras and a vaudeville troupe. The boat returned to New Orleans in time for the council meeting, held at ten o'clock P.M. at the Hotel Grunewald. On Thursday morning, April 1, after addresses of welcome by Hon. Martin Behrman, mayor of New Orleans, and President Robert Sharp of Tulane University, and an appropriate response from President Charles H. Herty of the society, the general meeting was called to order. Professor Alfred Werner, of the University of Zurich, having been duly nominated and having received a majority vote of the council, was elected to honorary membership in the society. The meeting then listened to an address by A. D. Little on "The Industrial Resources and Opportunities of the South." Following this address, the Industrial Division held a public symposium throughout the day, presenting the following papers, all of which, with the exception of the paper by H. A. Huston, have been printed in the April, 1915, issue of the *Journal of Industrial and Engineering Chemistry*.

Contributions of the Chemist to the Wine Industry: Charles S. Ash, consulting chemist.

Contributions of the Chemist to the Copper Industry: J. B. F. Herreshoff, vice-president Nichols Copper Company and consulting engineer General Chemical Company.

Contributions of the Chemist to the Corn Products Industry: E. T. Bedford, president Corn Products Refining Company.

Contributions of the Chemist to the Asphalt Industry: James Lewis Rake, secretary The Barber Asphalt Paving Company.

Contributions of the Chemist to the Cotton-seed Oil Industry: David Wesson, manager of the Technical Department, Southern Cotton Oil Company.

Contributions of the Chemist to the Cement Industry: G. S. Brown, president Alpha Portland Cement Company.

Contributions of the Chemist to the Sugar Industry: W. D. Horne, consulting chemist.

Contributions of the Chemist to the Incandescent Gas Mantle Industry: Sidney Mason, president of the Welsbach Company.

Contributions of the Chemist to the Textile Industry: Franklin W. Hobbs, President Arlington Mills, and Past President American Cotton Manufacturers' Association.

Contributions of the Chemist to the Fertilizer Industry: H. Walker Wallace, Manager General Sales Department, Virginia-Carolina Chemical Company.

Contributions of the Chemist to the Soda Industry: F. R. Hazard, President of the Solvay Process Company.

Contributions of the Chemist to the Leather Industry: William H. Teas, President Marion Extract Company.

Contributions of the Chemist to the Flour Industry: John A. Wesener and George L. Teller, Consulting Chemists.

Contributions of the Chemist to the Brewing Industry: Gaston D. Thevenot, Consulting Chemist.

Contributions of the Chemist to the Preserved Foods Industry: R. I. Bantley, Vice-president and General Manager California Fruit Cannery Association.

Contributions of the Chemist to the Potable Water Industry: Wm. P. Mason, Professor of Chemistry, Rensselaer Polytechnic Institute.

Contributions of the Chemist to the Celluloid and Nitro-cellulose Industry: R. C. Schupphaus, Consulting Chemist.

Contributions of the Chemist to the Glass Industry: A. A. Houghton, Vice-President Corning Glass Works.

Contributions of the Chemist to the Pulp and Paper Industry: F. L. Moore, president American Paper and Pulp Association.

The Strasfurt Potash Industry: H. A. Huston.

A complimentary luncheon was served at the Tulane refectory, the university being host. On Thursday evening a public address to the people of New Orleans by Bernhard C. Hesse, entitled "The Chemists' Contribution to the Industrial Development of the United States—A Record of Achievement," was given at the Hotel Grunwald, a large attendance being present. On Friday divisional meetings were held, before which one hundred and fifty-three papers were presented. The details of these papers and a further description of the meetings will be found in the May issue of the *Journal of Industrial and Engineering Chemistry*. Friday evening a subscription dinner was held at the Restaurant de la Louisiane, which will long be remembered by those present for the charming company and the creole cuisine. On Saturday one hundred of the members took a special train to Weeks Island and visited the famous salt-mine of the Myles Salt Co. The train went through the bayou region of Louisiana, made famous by Longfellow's poem, "Evangeline." The newly planted sugar-fields and the swamps, with their Spanish moss and the early tropical herbage, were attractive to all. The mine, which is an unusual one, was entered by a shaft six hundred feet deep, the bottom of which opened into galleries cut in solid salt many hundred feet long and eighty-five feet high by eighty-five feet wide, entirely unsupported by timbers. The salt, approximately 99.9 per cent. pure, is simply blasted out, carried to the surface, screened to various sizes, and placed on the market. The party returned to New Orleans in time to catch the evening trains. Many ladies were present at the meeting and, under the charge of the committee of which Mrs. E. J. Northrup was chairman, received many attentions from the people of New Orleans.

The ladies were present at the smoker and at the banquet and took the salt-mine excursion and were given a special trip through the Vieux Carre and to the Newcomb Pottery, and they had a dinner of their own at one of the famous local restaurants. One hundred and seventy-five members and approximately one hundred and twenty-five guests were present, so that the meeting was a very successful one from the point of numbers, considering the distance of New Orleans from the chemical center of the country. Meetings of

the following divisions were held, full programs of which will appear in the May issue of the *Journal of Industrial and Engineering Chemistry*:

Industrial Chemists and Chemical Engineers.—H. E. Howe, in the absence of the chairman, was in charge. The following committees were appointed: Committee on Standard Specifications and Methods of Analysis: (Chairman not appointed), A. M. Comey, J. O. Handy, Robert Job, F. G. Stantial. Committee on Non-ferrous Metals and Alloys, a subcommittee of the committee on standard specifications: Wm. Price, chairman, Allen Merrill, Geo. L. Heath, Gilbert Rigg, Bruno Woiciehewski.

Committee on Soap Products: Archibald Campbell, chairman, C. P. Long, J. R. Powell, Percy H. Walker.

Committee on Glycerine, a subcommittee of the Committee on Soap Products: A. C. Langmuir, chairman, W. H. Low, S. S. Emery, R. E. Devine, J. W. Loveland, A. M. Comey.

Committee on Naval Stores: J. E. Teeple, chairman (other members not yet selected).

Committee on Alum: W. M. Booth, chairman, Chas. P. Hoover, Wm. C. Carnell.

Committee on Platinum: W. F. Hillebrand, chairman, Percy H. Walker, H. T. Allen.

Physical and Inorganic Chemistry.—E. P. Schoch, in the absence of the chairman, was in charge.

Fertilizer Chemistry.—Chairman J. E. Breckenridge was in charge.

Agricultural and Food Chemistry.—Chairman Floyd W. Robison was in charge.

Organic Chemistry.—C. G. Derick, in the absence of the chairman, was in charge.

Pharmaceutical Chemistry.—Chairman F. R. Eldred was in charge.

Biological Chemistry.—Chairman C. L. Alsberg was in charge.

Water, Sewage and Sanitation.—The following officers were elected: Edward Bartow, chairman; E. B. Phelps, vice-chairman; H. P. Corson, secretary; executive committee—the officers and C. P. Hoover and E. H. S. Bailey.

CHARLES L. PARSONS,
Secretary

THE AMERICAN MATHEMATICAL SOCIETY

THE one hundred and seventy-seventh regular meeting of the society was held at Columbia University on Saturday, April 24, seventy-one mem-

bers being in attendance at the two sessions. President E. W. Brown occupied the chair, being relieved by ex-presidents Osgood, Moore and White and Vice-president Veblen. The following were elected to membership in the society: Professor L. S. Hill, University of Montana; Miss G. I. McCain, Indiana University; Mr. J. L. Riley, Rice Institute. Eleven applications for membership were received.

The invitation of Harvard University to hold the summer meeting and colloquium of the society at Harvard in 1916 was accepted. The annual meeting will be held in New York City in December. Committees were appointed to arrange for these meetings and to present a list of nominations for officers for 1916. Professor P. F. Smith was reelected a member of the editorial committee of the *Transactions*.

Reports of the committees were received regarding the movement against mathematics in the schools and the possible relations of the society to the field now covered by the *American Mathematical Monthly*. It was decided that in the former matter no action of the society was at present advisable. The relations of the society to the field covered by the *Monthly* were carefully considered and the sense of the Council was embodied in the following resolution: "It is deemed unwise for the American Mathematical Society to enter into the activities of the special field now covered by the *American Mathematical Monthly*; but the council desires to express its realization of the importance of the work in this field and its value to mathematical science, and to say that should an organization be formed to deal specifically with this work, the society would entertain toward such an organization only feelings of hearty goodwill and encouragement."

The following papers were read at this meeting:

C. J. de la Vallée-Poussin: "Démonstration simplifiée d'un théorème de Vitali sur le passage à la limite sous le signe d'intégration."

C. A. Fischer: "Minima of double integrals with respect to one-sided variations."

G. M. Green: "Nets of space curves."

R. L. Moore: "A set of axioms in terms of point, region and motion."

R. L. Moore: "On the categoricity of a set of postulates."

H. S. Vandiver: "A property of cyclotomic integers and its relation to Fermat's last theorem. Second paper."

J. F. Ritt: "The reduction of invariant equations."

E. B. Wilson: "Linear momentum, kinetic energy and angular momentum."

F. H. Safford: "An irrational transformation of the Weierstrass \wp -function curves."

Arnold Emch: "A certain class of functions connected with Fuchsian groups."

G. D. Birkhoff: "An elementary double inequality for the root of an algebraic equation having greatest absolute value."

H. S. White and Louise D. Cummings: "Groupless triad systems on 15 elements."

Edward Kasner: "Conformal geometry in the complex domain."

Edward Kasner: "Convergence proofs connected with equilog invariants."

E. V. Huntington: "Notes on the catenary, including the case of an extensible chain."

R. C. Strachan: "Note on the catenary."

J. E. Rowe: "A property of the osculant conic of the rational cubic."

J. E. Rowe: "The node of the rational cubic as a rational curve in lines."

Dr. F. W. Beal: "A congruence of circles."

H. F. Stecker: "Linear integral equations whose solutions have only a finite number of terms."

C. A. Epperson: "Note on Green's theorem."

L. J. Reed: "Some fundamental systems of formal modular invariants and covariants."

J. R. Kline: "Double elliptic geometry in terms of point and order."

Alexander Pell: "On the curves of constant torsion."

J. W. Young and F. M. Morgan: "The geometries associated with a certain system of Cremona groups."

T. H. Gronwall: "A functional equation in the kinetic theory of gases."

J. W. Alexander, II: "A theorem on conformal representation."

J. H. Weaver: "The Collection of Pappus."

A meeting of the society was held in Chicago on April 2-3. The summer meeting will be held at the University of California and Stanford University, August 3-5.

F. N. COLLE

Secretary

SOCIETIES AND ACADEMIES

THE UTAH ACADEMY OF SCIENCES

THE eighth annual convention of the Utah Academy of Sciences was held in the chemistry lecture room of the University of Utah. Three sessions were held: one at eight P.M., Friday, April 2, one at 10 A.M., Saturday, April 3, and the closing meeting at two P.M., the same day.

President Marcus E. Jones occupied the chair at all the sessions.

Professor Byron Cummings, U. U., Dr. W. E. Carroll, U. A. C. and Dr. Helen I. Mattill, U. U., were elected to fellowships, and Isaac Diehl (Robinson, Utah), H. J. Maughan, U. A. C., Miss Mary Morehead, U. U., James R. Smith (Heber City), and Chas. E. Mau, B. Y. U., to membership in the academy.

The officers for the ensuing year are as follows:

President—Dr. Harvey Fletcher, B. Y. U., Provo.

First Vice-president—Dr. Frank Harris, U. A. C., Logan.

Second Vice-president—Dr. L. L. Daines, B. Y. U., Logan.

Permanent Secretary-treasurer—A. O. Garrett, Salt Lake High School.

Councillors—Professor J. L. Gibson, U. U., W. D. Neal, Salt Lake City, Dr. W. E. Carroll, U. A. C., Logan.

A committee was appointed to make arrangements for publication of the proceedings of the academy.

The following papers and lectures were presented:

"The Rights and Duties of the Scientist," by Professor Marcus E. Jones.

"The Textile Fabrics of the Cliff Dwellers," by Professor Byron Cummings, U. U. (Illustrated by numerous specimens taken from cliff dwellings.)

"Controlling Grasshoppers," by Dr. E. D. Ball, U. A. C.

"Effect of Soil Alkali on Plant Growth," by Dr. Frank Harris, U. A. C.

"Some Unique Busts," by A. O. Garrett, Salt Lake High School.

"Effect of the Amount of Protein Consumed upon the Digestion and Protein Metabolism in Lambs and upon the Composition of their Flesh and Blood," by Dr. W. E. Carroll, U. A. C.

"A Determination of Avogadro's Constant N ," by Dr. Harvey Fletcher, B. Y. U.

"The Voice Tonoscope," by Dr. Franklin O. Smith, U. U.

"The Origin of Higher Orders of Difference Tones: Experimental," by Dr. Joseph Peterson, U. U.

"The Hot Air Furnace—A Study of Combustion," by Dr. W. C. Ebaugh, U. U.

"Color Photography," by Dr. Chas. T. Vorhies, U. U., and Professor Marcus E. Jones. (Illustrated by lantern projections of numerous color photographs taken independently by Dr. Vorhies

and Professor Jones in Big Cottonwood Canyon and other parts of Utah.) A. O. GARRETT,

Secretary

THE ANTHROPOLOGICAL SOCIETY OF WASHINGTON

At the 482d meeting of the society, held February 2, 1915, Dr. C. L. G. Anderson read an obituary on Dr. A. F. A. King, who died in Washington, December 13, 1914. Born in England in 1841 and coming to Virginia in boyhood, he graduated in medicine, both at Washington and at Philadelphia. Soon after the Civil War he served as surgeon at the Lincoln Hospital. From 1870 until his death he held medical chairs in Washington and the University of Vermont and made many contributions to medical and scientific literature. Among his anthropological papers was one on "The Evolution of Marriage Ceremony and its Import."

At the 483d meeting of the society, held February 16, 1915, a paper was read by Mr. William H. Babcock on "The Races of Britain." Three native languages have been spoken in parts of Great Britain since the sixth century. They represent three waves of invasion by blond peoples. The dark admixture in Britain comes from an earlier population, a fairly advanced neolithic race, probably from southern Europe, which perhaps had absorbed paleolithic remnants found in the island. Reports were made on several recent scientific trips. Professor W. H. Holmes and Dr. Aleš Hrdlička installed exhibits in Indian ethnology and physical anthropology for the Panama-California Exposition. These are new and very important and will form parts of permanent museums. Dr. J. W. Fewkes proved prehistoric cultural interchanges between Mexico and our southwest in the ruins of the valleys of the Santa Cruz in Arizona and of the Mimbres in New Mexico. The former are of the Casa Grande type. More than 800 specimens were brought back, including 250 of painted pottery. Dr. Truman Michelson found scarcely a dozen of the 600 Stockbridge now in Wisconsin who remember a few Stockbridge words. The language was definitely placed in the Pequot-Mohican and Natick division of central Algonquian dialects, although related to the Delaware-Munsee. Among the Brothertowns near Lake Winnebago, not one was found who remembered Brothertown words. Mr. J. N. B. Hewitt found on his trip to Canada only one survivor who remembered anything of the Naticke dialect. He also studied the place of song in the ceremonial of an Iroquois lodge.

I wish to dwell in this paper not on the scientific attainments and successes of Charles Sedgwick Minot, but on the mental and moral qualities which his career illustrates and which made him what he was.

Young Minot did not follow the traditional course of education for the son of a well-to-do Boston lawyer. He did not go to Harvard College, but to the Massachusetts Institute of Technology and his first degree, that of bachelor of science, was obtained from that technical school. His major subject in that school was not the common one of engineering, but the uncommon one of natural history. He later pursued his studies in this unusual subject at Leipzig, Würzburg and Paris. Then, returning to Boston, he took the degree of doctor of science at Harvard University in 1878, again in the subject of natural history. His education, therefore, showed his determination in following his bent, and his independence in parting from his boyhood associates and his family's habitual practise in regard to the education of sons.

Then, as now, the only career open to students of natural history was a professorship in some branch of that subject, but this was not the career to which Minot looked forward. His studies were all histological and embryological, and their most practical and useful applications seemed to him to lie somewhere in the field of medical science and education.

Two years later he accepted two ap-

¹ Address before the Boston Society of Natural History at a memorial meeting held on March 17, 1915.

² Intended for publication and books, etc., intended for review should be sent to Professor J. McKeen Cattell, Garrison-
place, Hudson, N. Y.

pointments in connection with Harvard University; one an appointment as lecturer in embryology in the medical school; the other an appointment as instructor in oral pathology and surgery in the dental school.

These appointments were procured for him with some difficulty, for he was not a doctor of medicine, and it was an unwelcome idea for the medical faculty that any instruction whatever should be given in the medical school by a person who had never taken the degree of doctor of medicine.

He accepted both these appointments with alacrity, although dentistry was not recognized then as a medical specialty, and immediately showed himself to be a competent lecturer and laboratory teacher in subjects which depended on the facile use of the microscope by both teacher and students. The place he took in the dental school had, just previously, been filled by Arthur Tracy Cabot, who had shown by his acceptance of that appointment his sympathy with the efforts of the university to lift and improve the dental school and the dental profession, and his prophetic belief that the relations between dentistry and clinical medicine were to become much more intimate than they had been.

In 1883, Minot was advanced to the position of instructor in histology and embryology, and this subject was given a satisfactory place in the curriculum of the medical school. There was still resistance to the appointment of a teacher who did not hold the degree of doctor of medicine, but Minot had, in three years, proved not only that he was the vigorous teacher, but that he had business qualities which would make him a remarkably good director of a laboratory for the instruction of medical students. He devised an excellent method of buying microscopes for the whole class and loaning them to students for a term fee which was sufficient to keep every microscope in repair and in time to repay their whole cost.

He studied every detail of the furniture and fittings of a medical laboratory and decided on the shape and the size of the desk room which each student needed. He made highly intelligent use of the card catalogue for his growing collection of embryological specimens, for his library and for his student records. He became expert in everything relating to the conduct of a laboratory and set a good example to all the other teachers who were conducting laboratories in the medical school. As the school was then in the process of changing from a school in which the lecture predominated to a school in which the laboratory predominated, Minot became more and more useful to the medical school as a whole.

In the year 1887, it was possible to appoint him to an assistant professorship of histology and embryology. At the expiration of the usual term for an assistant professor (five years) he was made professor of histology and human embryology, and in this appointment, with its new title, Minot's special subjects and his high merits both in teaching and in research were fully recognized.

Between 1881 and 1883, the medical faculty planned and erected a new building for its own use on Boylston Street, at the corner of Exeter Street—a building in which laboratories occupied a large part. Minot obtained for his courses an excellent laboratory of his own planning. There, in twenty years, he built up his unique embryological collection; a monument to his insight, skill, industry and power of inspiring others with his own zeal. In less than twenty years this building became inadequate for the best development of the medical school, and the new buildings of 1906 began to be planned. The fundamental consideration in planning and constructing the new buildings was to adapt them thoroughly to the new method of instruction in

medicine—a method which relied chiefly on individual instruction and laboratory work. Minot's careful study of the best laboratory conditions for small sections, in well-lighted and well-ventilated rooms, with a desk for each student, was taken up again and contributed much to the final success of the architect's plans. The accommodations for the department of histology and human embryology conformed to Minot's conception of the present and future needs of his department and served as a type for the laboratories of other departments in the school.

It became possible to enlarge the number of teachers employed in the department, and its intimate connection with the teaching of anatomy was recognized. When Dr. Thomas Dwight, professor of anatomy since 1883, died in 1911, the school was fully prepared to recognize the fact that anatomy and histology belonged together. In the mean time, the James Stillman professorship of comparative anatomy had been endowed and to that Professor Minot had been transferred in 1905. No professor of anatomy was appointed to succeed Dr. Dwight, but in 1912 Minot was made director of the anatomical laboratories in the Harvard Medical School. This action of the faculty and the corporation crowned Minot's professional career as a student and teacher of natural history, applied in medical education. By clear merit he had made his way and the way of his department in the school and without a medical degree had become the head of anatomical teaching in a medical school. Under him in the anatomical department were two assistant professors, one of whom was called assistant professor of anatomy and the other of histology. Fourteen other teachers were employed in the department of anatomy and histology, three of whom bore the title of histology and embryology, Minot's original subjects in the medical school.

Minot's advance through the medical school was not facilitated by a yielding or compromising disposition, or any practise of that sort on his part. On the contrary, he pursued his ends with clear-sighted intensity and indomitable persistence; suavity and geniality were not his leading characteristics in discussion or competition and he often found it hard to see that his opponent had some reason on his side. Like most independent and resolute thinkers, he had confidence in the soundness of his own reasoning, and in the justice of the cause or movement he had espoused.

He was upright in every sense of that word. His loyalty was firm and undeviating, whether to an ideal or a person or an institution, and affection and devotion, once planted in his breast, held for good and all.

His book on "Human Embryology" published in 1892 made him famous throughout the learned world, so that he was elected to learned societies in Great Britain, Italy, France, Germany and Belgium; as well as to all appropriate American societies. He also received honorary degrees from the universities of St. Andrew's (Scotland), Oxford (England), Toronto (Canada), and Yale. He enjoyed calmly and simply the honors thus paid to his scientific attainments and services by well informed and impartial judges.

In 1913 he was Harvard exchange professor at the universities of Berlin and Vienna, where he gladly availed himself of many opportunities to expound to his German colleagues the advances in natural history, including medicine, which were due to American investigators.

His hair and beard were now whitening, but he felt all the ardors of youth, and among them, fervid patriotism. In scientific investigation Minot showed imagination, penetration and eagerness, but also caution. In 1907 he gave a course of lectures at the Lowell Institute on "Age,

Growth and Death" and made them the basis of a book published the following year. For him, the subject meant cell metamorphosis, with which he had been familiar through all his studies in histology and embryology, but what he sought in this subject of "Age, Growth and Death" was a scientific solution of the problem of old age which should have—I quote his words—"in our minds, the character of a safe, sound and trustworthy biological conclusion." He ventured to think that some contemporary students of the phenomena of longevity had failed to exercise sufficient caution in forming their conclusions. Nevertheless, Minot was a scientific optimist; full of hope for perpetual progress and for useful results at many stages of the long way. These characteristics appeared clearly in the following passage, taken from the first lecture of that course at the Lowell Institute:

I hope before I finish to convince you that we are already able to establish certain significant generalizations as to what is essential in the change from youth to old age, and that in consequence of these generalizations now possible to us new problems present themselves to our minds, which we hope really to be able to solve, and that in the solving of them we shall gain a sort of knowledge which is likely to be not only highly interesting to the scientific biologist, but also to prove in the end of great practical value.

There spoke the cautious, modest, hopeful scientist, expectant of good. Such is the faith which inspires the devoted lives of scientific inquirers.

CHARLES W. ELIOT

THE STIMULATION OF GROWTH:

I

THE growth of living organisms differs from that of crystals in three essential features. While the crystal grows only in a supersaturated solution of its own sub-

¹Read at the meeting of the National Academy in Washington, April 19, 1915.

stance, living organisms can grow indefinitely in even a very low concentration of their nutritive solution; second, the nutritive solution need not and perhaps should not contain the compounds found in the cells, but only their split products, while in the case of the crystal the substance of crystal and solute must be identical. And thirdly, growth leads in living cells to the process of cell division as soon as the mass of the cell reaches a certain limit. Needless to say this process of cell division can not even metaphorically be claimed to exist in a crystal.

The fact that the cell can grow in a very low concentration of its nutritive solution, and the further fact that the nutritive solution only needs to contain the building stones for the complicated compounds of the cell, find their explanation in the assumption of the existence of synthetic enzymes or synthetic mechanisms in the cell.

The problem of growth is linked with that of death and immortality, since it would follow from our definition that the growth of a cell should go on eternally in a proper nutritive solution and under suitable conditions of temperature, provided that the synthetic catalyzers last and that they synthesize their own substance.² This is apparently true for bacteria and perhaps also for protozoa. Weismann has claimed immortality for all unicellular organisms and for the sex cells of metazoa, while he concedes mortality to the body cells. Leo Loeb recognized that immortality may be claimed also for the cells of malignant tumors, like cancer, for he had found that when he transplanted cancer cells on other animals the cells of the original cancer and

² This latter assumption leads to the connection of the problem of growth with that of autocatalysis as suggested first by the writer in 1906 and worked out subsequently in the papers of W. Ostwald and T. B. Robertson.

not the cells of the host grow into a new cancer. He suggested in 1901 that this claim might be extended to somatic cells in general.

The idea suggests itself that not only the germ cells can be immortal, but that perhaps also the somatic cells, like connective tissue cells, might, under certain conditions, live for a long period, much longer than the individual life of the organism of which they were a part, that they might perhaps also be immortal in the same sense as the ovum is.³

Returning to the same problem in 1907 he added the following remarks:

There exists another very striking phenomenon in the growth of malignant tumors, to which I called attention in my first communications on the transplantation of tumors, namely the fact that tumor cells have apparently an unlimited existence and that they seem to resemble in this respect the germ cells. It is certain that their life and growth exceeds that of the other somatic cells of the individual, from which they are taken. But at present we are not yet justified in saying that the tumor cells differ in this specifically from certain other somatic cells. It has been tacitly assumed thus far that the somatic cells of the metazoa have only a limited existence, but no attempt has been made to determine exactly the possible duration of life of somatic cells. We must therefore consider the possibility that certain somatic cells possess the same apparently unlimited duration of life as somatic tumor cells. . . . This seems to be a biological problem of great bearing to which the experimental investigation of tumors has led, and it might be possible to decide experimentally whether or not other cells resemble tumor cells in this respect.⁴

The experimental decision seems to have been furnished, since Carrel has succeeded in keeping connective tissue cells from a chick embryo alive for over three years, and these cells are still growing and dividing. It should be added, however, that similar attempts with other cells have not yet met with the same success.

³ Leo Loeb, "On Transplantation of Tumors," *Jour. Med. Res.*, VI., 28, 1901.

⁴ Leo Loeb, "Beiträge zur Analyse des Gewebewachstums," *Arch. f. Entwicklungsgesch.*, XXIV., 665, 1907.

While thus theory and experience seem to agree to some extent, a closer examination of actual conditions reveals a somewhat different and more complicated situation. The egg cell, for which Weismann claimed immortality, can not grow and develop and will die quickly if it is not fertilized at a certain stage of its existence. The cells in the body will not grow constantly as our definition seems to demand, but their growth is followed by a period of rest from which they may be aroused by special substances or by a wound. Moreover, all differentiation of form in animals and plants depends on the fact that the different parts grow with different velocities, since otherwise all organisms would be perfect spheres.

In reality then the resting condition of a cell seems to be as much a part of real life as growth and cell division. Yet the definition from which we started is apparently correct, and it may be that we have to define the additional conditions which make a resting cell possible and which will wake a resting cell from its slumber.

II

In the usual treatment of the problem of growth the increase of mass of the whole organism is taken into consideration. While this method is adequate for the study of the relation of nutrition to growth, it is not adequate for the study of the stimulation of growth. In the latter case we must remember that it is the individual cell which grows, and that we must therefore study the mechanism of this stimulation in the individual cell and not in the organism as a whole. The ideal object for this study is the egg cell, since we can observe it in the condition of rest as well as of cell division and growth.

Since usually cell division follows growth and is possibly a consequence of the increase of mass of the cell, this rule does not

always hold in the egg cell, where as a rule immediately after fertilization a series of cell divisions follow without any increase of mass of the egg. The egg, when divided into two or more cells, does, as a rule, not weigh more (and may possibly weigh a little less) than the original egg cell before it began to divide. This exception from the rule that cell division is preceded by growth of the cell is not real, since the egg cell is at first much larger than the ordinary body cell of the growing organism. If the relation between size of cell and cell division exists we must expect that the egg cell after it is fertilized must first undergo a series of cell divisions without any growth, until each cell of the original egg has been reduced to the size of the cell characteristic for the species. Only after this has happened can the ordinary cycle of growth of the cell with subsequent cell division begin.

The writer is suspicious that even in eggs where we notice at first cell division without growth, in reality growth may take place. Such eggs as those of the sea urchin consist largely of reserve material which is gradually transformed into the peculiar state which we designate as living protoplasm (and which may differ from non-protoplasmic material in the possession of synthesizing enzymes or mechanisms). In the first stages of cell division this transformation of reserve material into living material may occur, and this transformation is the real growth which we observe in the bacteria and later on in the cells of metazoa, but which is not directly visible in the first stages of cell division in the egg.

The unfertilized egg immediately before fertilization is usually unable to divide even under the most perfect conditions. With all the food existing in a hen's egg the germ can not grow unless it is fertilized, while this growth takes place after a spermatozoon has entered the egg. There exists, therefore, a mechanism by which the

same egg cell can be in a state of rest in which growth is inhibited. What is the nature of this peculiar inhibitory mechanism and what is the mechanism by which the entrance of a spermatozoon abolishes this inhibition? The experiments on artificial parthenogenesis⁵ allow us to give a partial answer to this question.

In the case of certain eggs, *e. g.*, the egg of the sea urchin, the entrance of a spermatozoon is followed immediately by a striking change in the surface of the egg. The latter surrounds itself with the so-called fertilization membrane. If we induce this membrane formation by certain chemicals (*e. g.*, a short treatment with a fatty acid) the eggs when put back into normal sea water will begin to develop at a low temperature and may reach the larval stage. But at the temperature of the room or even of the ocean the eggs may begin to develop, but they will perish the more rapidly the higher the temperature. On the other hand, the eggs if fertilized with sperm will develop at room temperature. What causes this difference? The answer is that the alteration of the surface of the egg induced by a fatty acid initiates development but is not sufficient to guarantee a normal development at ordinary conditions. For this purpose a second treatment is required and this can be given in the form of a short treatment with a hypertonic solution or a longer treatment with lack of oxygen. After the egg has received the second treatment it can develop into a normal larva at room temperature. I am suspicious that even a third factor may have to be supplied, since the mortality of the parthenogenetic larva is greater than that of the normally fertilized eggs.

Why is it that the membrane formation, or more correctly an alteration of the sur-

⁵ The reader is referred to the writer's book on "Artificial Parthenogenesis and Fertilisation," Chicago, 1913, for details and literature.

face layer of the egg, which may or may not result in a membrane formation, starts the development of the egg? The writer had found that the fertilized egg can not develop if deprived of oxygen, but that development begins again instantly if oxygen is admitted. From this and other observations he concluded that fertilization by sperm as well as artificial membrane formation induced development by raising the rate of the oxidations in the egg, and this surmise was confirmed by actual measurements by O. Warburg as well as by Wasteneys and the writer.* It was found that the entrance of a spermatozoon into the egg raises the rate of oxidations from 400 per cent. (*Arbacia*) to 600 per cent. (*Strongylocentrotus purpuratus*) and that artificial membrane formation by butyric acid raises the rate of oxidations to exactly the same amount.

The changes which determine this characteristic rise in the rate of oxidations of the egg are situated at the surface of the egg, in its cortical layer. The process underlying membrane formation can be called forth by any substance which causes cytolysis—that form of destruction of the cell which results in the transformation of a cell into a mere shadowy skeleton. Any cytolytic agent will induce membrane formation and also development in the unfertilized egg, if it is allowed to act on the superficial layer of the egg only, i. e., if the egg is removed from its influence after the membrane formation. If it is not removed the whole egg will undergo cytolysis and can no longer develop. But such eggs will still show the rise in the rate of oxidations which follows artificial membrane formation, thus indicating that the sudden rise in the rate of oxidations which we notice after

artificial membrane formation depends only upon the alteration of the surface of the egg, regardless of the condition of the rest of the egg.

The forces which induce the egg cell to develop are, therefore, localized at the surface of the cell and consist in a change (possibly a cytolysis) of the cortical layer of the egg. We do not know how this change induces the rise in the rate of oxidations upon which development depends, but from Warburg's work it appears probable that the oxidations in the sea urchin egg are due to a catalysis by iron. This would indicate the possibility that in the cytolysis of the cortical layer of the egg the iron would be transformed from a condition where it is unable to act as a catalyzer into a condition where it can act in this capacity.

We have mentioned the fact that all cytolytic agencies call forth the membrane formation in the unfertilized egg. Such cytolytic substances (the lysins of the bacteriologist) are also contained in the blood and cell extract of each animal; only with this limitation that the cells of our own body are immune against the action of our own lysins, but not against the lysins in the blood and cell extract of other animals. I was able to show that we can call forth membrane formation and development in the sea urchin egg with foreign blood, e. g., ox blood, or with the extracts of foreign tissues, but not with their own blood or tissue extract. Wasteneys and the writer could show later that this method can be applied generally for artificial parthenogenesis. This immunity of the egg towards the lysins of its own body we may explain on the assumption that the lysins contained in foreign blood can enter the cell, while the latter is impermeable for the lysins contained in the blood or tissue extract of the same species. If it were not for this immunity, all the eggs would be induced to

*There are indications that other processes are also initiated or accelerated by fertilization, but this may be omitted from consideration in this connection.

develop before they leave the ovary. This is not the case.

The work on physiologically balanced salt solutions has brought out the fact that the permeability of the cells in a body may undergo variations and when this happens it is conceivable that the lysins in the blood may induce eggs to develop in the ovary. Leo Loeb states that 10 per cent. of the eggs in the ovary of a guinea-pig may show a beginning of parthenogenetic development, and certain spontaneous tumor formations in the human ovary may find their explanation in this way. In other words, it is not excluded that one form of limited growth may be due to the immunity or impermeability of cells to blood of the same species.

The question then why an unfertilized egg can not grow and why a fertilized egg possesses the power of dividing and growing is therefore answered in the sense that both conditions depend apparently upon the condition of the surface layer of the cell.

The most important fact for our present problem is the observation that the alteration which starts the development of the egg is to some extent reversible. The history of the egg is such that after a number of cell divisions the final stage of the unfertilized egg ready for fertilization is reached. If at that stage it is fertilized by sperm or induced to develop by artificial means the processes of cell division and growth will continue; if not, the egg will soon die. There is a third possibility. The unfertilized egg may start to develop, then stop and go practically, though not entirely, back into the state in which it was before starting to develop.

The clearest case of this kind was observed in the egg of the Californian sea urchin. When the unfertilized egg of *Strongylocentrotus purpuratus* is treated

with a hypertonic solution the eggs may begin to segment into two, four, or eight or sixteen cells, but then they cease developing and go back into the resting condition in which they were before the egg started dividing, with the exception of one condition which will be mentioned later. In the place of each of the original eggs we have now two, four, eight, etc., smaller cells. The observation is of importance for the theory of fertilization, because it disposes of the idea once held by Boveri that eggs are in the resting stage because they are lacking the apparatus for cell division; these eggs went into the resting stage again in spite of the fact that they possessed the apparatus for normal cell division. If the cells of such an egg are at a later time fertilized with sperm, they form a fertilization membrane and develop. They will develop also into larvæ if they only receive the butyric-acid treatment without the corrective factor. The original treatment with the hypertonic solution provided these eggs permanently with the corrective effect.

What caused these eggs which were segmenting to go back into the resting stage? I am inclined to assume that in these eggs the change in the cortical layer which started the development was gradually or suddenly reversed. We should expect this to betray itself in a lowering of the rate of oxidations. Wasteneys and I have found indeed that unfertilized eggs of *purpuratus*, which show an increase in the rate of oxidations after a treatment with a hypertonic solution, show a lower rate if examined after some time. It seems then possible that the change in the cortical layer which leads to a rise in the rate of oxidations is under certain conditions reversible.

These are not the only cases of reversion. I noticed that if the development of the eggs of *Arbacia* is induced either by a

treatment with butyric acid or by alkali, and if the eggs are afterwards prevented from developing (by putting them for a certain length of time into sea water containing NaCN) they will go back into a resting condition from which they can be aroused again by a treatment with sperm. We suspect that in this case the reversion in development is also accompanied by a reversion in the rate of oxidations.

We see then that our definition of a cell as being constantly ready to grow and segment is not strictly fulfilled even in the case of the egg cell, which, according to Weismann, we may consider as immortal. Instead we see that the egg cell can apparently alternate between a resting condition and an active condition, and that the nature of the cortical layer of the egg determines in which of the two conditions the egg exists.

From this we might conclude that our original definition, that each cell will grow and multiply eternally, may hold after all if we add the fact, that in the egg cell a variation in the nature of the cortical layer may start or inhibit cell division and growth. We may next ask: Does this addition also satisfy the facts we find in the adult body where the cells come to rest unless they are called into active growth again by a wound or by the not definitely known causes of tumor formation? Or, in other words: Is it only a change in the cortical layer which condemns the cells of the adult body to rest and those of the young body to grow?

Unfortunately, our task is not so easy. The unfertilized egg which is ready for fertilization will die comparatively rapidly, unless it is fertilized by sperm or treated by the methods of artificial parthenogenesis. We can prolong its life by suppressing its oxidations. Before the egg is mature its duration of life seems longer.

If the eggs of the starfish are allowed to mature they die in a few hours if not fertilized; if they are prevented from becoming mature they live much longer. It is not known that anything similar to this exists in the somatic cells of the adult animal. Until such knowledge is acquired we must be prepared to admit that the resting cell of an adult organism is in a condition which is not comparable to that of the unfertilized egg.

III

We know that the growth of resting cells in a body may be induced if the blood contains certain substances which differ for different kinds of cells. One of the most recent and most striking observations in this direction was that of Gudernatsch, who found that in the tadpole of a frog or a toad, whose legs usually do not begin to grow until it is several months old, the legs can be induced to grow out at any time, even in very young specimens, by feeding them with the substance from thyroid glands. No other material seems to have such an effect. The thyroid contains iodine, and Morse states that if instead of the gland iodized amino-acids are fed the same result can be produced. We must draw the conclusion that the normal outgrowth of legs in a tadpole is also due to the presence in the body of substances similar to the thyroid in their action (it may possibly be thyroid substance) which is either formed in the body or taken up with the food.

That the phenomena of larval metamorphosis are independent of the influence of the central nervous system has been amply demonstrated. Thus I could show in 1896 that if we cut through the spinal cord of an amblystoma larva the metamorphosis of the body in front and behind the cut takes place simultaneously. Uhlen-

huth showed that if the eye of a salamander larva is transplanted into another larva the transplanted eye undergoes its metamorphosis into the typical eye of the adult form simultaneously with the normal eyes of the individual into which it was transplanted. These and other observations of a similar character show that substances circulating in the blood are responsible for the phenomena of growth in this case.

A very instructive observation on the rôle of internal secretion on growth was made by Leo Loeb. When the fertilized ovum comes in contact with the wall of the uterus it calls forth a growth there, namely, the formation of the maternal placenta (decidua). Leo Loeb showed that the corpus luteum of the ovary gives off a substance to the blood which alters the tissues in the uterus in such a way that any contact with any foreign body induces this deciduoma formation. The case is of interest since it indicates that the substance given off by the corpus luteum does not induce growth directly, but that it allows mechanical contact with a foreign body to induce growth, while without the intervention of the corpus luteum substance no such effect of the mechanical stimulus would be observable. The action of the substance of the corpus luteum is independent of the nervous system, since in a uterus which has been cut out and retransplanted into the animal the same phenomenon can be observed.

All these cases agree in this, that apparently specific substances induce or favor growth not in the whole body, but in special parts of the body. This recalls the idea of Sachs that there must be in each organism as many specific organ-forming substances as there are organs in the body. When this statement was made by Sachs the facts on the specific effect of internal secretion were unknown. To-day we can

say that Sachs's theory is certainly supported by a stately array of facts.

There may also be substances which affect growth more generally. This is indicated in the apparent connection of acromegaly and giantism with diseases of the hypophysis and in the inhibition of longitudinal growth after extirpation of the thyroid.

We are, however, unable to answer the question as to how these substances induce the cells to grow. Are the resting cells in the body in the condition of the unfertilized egg and does the thyroid in Gubernatsch's experiment produce an alteration of the cortical layer of the cells from which the legs grow out, similar to that caused by the butyric-acid treatment of the egg? It would not be safe to make such an assumption at present, since we do not even know whether the products of internal secretion act directly on the growing cell or only in some indirect way. We only know that conditions of rest in the cells may be interrupted by the production of certain substances in the body or by their introduction in the form of food; and conversely we may suspect that the rest of the cells may have been enforced by the presence of other substances (or cells) in the blood antagonistic to the former.

The idea that the products of internal secretion or certain substances taken up in the food do not act directly upon the cells whose growth they influence, but indirectly through an alteration of metabolism, is strongly supported by the interesting observations of Geoffrey Smith. Claude Bernard and Vitton had shown that the period of growth and moulting of the higher Crustacea is accompanied by a heaping up of glycogen in the liver and subdermal connective tissue. Smith found that during the period between two moultings when there was no growth the storage cells are seen to be filled with large and numerous

fat globules instead of with glycogen. He also found that in the *Cladocera* "the period of active growth is accompanied by glycogen—as opposed to fat—metabolism." He observed, moreover, that if *Cladocera* are crowded at a low temperature the fat metabolism (with inhibition to growth) is favored, while at high temperatures and with no crowding of individuals the glycogen metabolism is favored. In the latter case a purely parthenogenetic mode of propagation is observed, while in the former sexual reproduction takes place. The effect of crowding of individuals is apparently due to products of excretion, which then act on growth and reproduction indirectly by modifying the "glycogen metabolism" to "fat metabolism."

IV

Factors which directly inhibit growth have been discovered by Jas. B. Murphy, of the Rockefeller Institute. It was known that tissues can not be successfully transplanted into a different species. Murphy discovered that this rule does not hold for the chick embryo. Any kind of tissue, even human, will grow if transplanted to such an embryo. This growth of the transplanted tissue will stop, however, when the chick is ready to hatch, and Murphy found that this is due to the development of a certain type of cells in the chick embryo at that period, namely, the lymphocytes. Murphy found, moreover, that he could put adult mice and rats also into the condition of tolerance to foreign tissues when he destroyed their lymphocytes by an exposure to X-rays. As soon as the lymphocytes are formed again foreign tissues can not grow any longer on the animal. In this case we have a definite inhibition of growth by the action of lymphocytes which collect around the transplanted piece. It is not yet possible to state to what extent this

observation on the inhibition of growth can be generalized.

We shall see later that possibly the opposite may also be true, namely, that certain cellular elements may have an accelerating effect on growth.

V

When a wound is made, cells which had been at rest may begin to grow. In many lower animal organisms and in plants whole organs may be induced to grow as a consequence of a mutilation. These phenomena are known under the name of regeneration. The name indicates the power of a living organism of restoring lost parts.

We can see from a physicochemical viewpoint why a cell should be endowed with a power of growing indefinitely, since we only need to assume the presence of suitable synthetic enzymes in the cell; but we fail to see from the same viewpoint why an organism should have the power of restoring lost parts. Weismann and others have tried to account for this power in a metaphysical way which was shown to be in conflict with the facts.

The statement that regeneration consists in the restoration of lost parts is not always the exact expression of the actual facts. In plants, *e. g.*, we notice—in the majority of cases—not a restoration of the lost parts but the outgrowth of one or more dormant buds which are often at some distance from the seat of injury. There has been some discussion whether in view of this fact we can say that regeneration exists in plants. This merely verbal difficulty disappears if we disregard the metaphysical sense of the term regeneration and realize that the essential feature of the phenomenon is the fact that if we wound living organisms, cells oranlagen which had ceased to grow suddenly begin to grow. Thus the problem of regeneration becomes a problem of

growth and the real question is: How can the process of wounding induce growth in cells which had been at rest and would probably have remained so during the whole term of life of the individual? It is not the wound in itself which induces the growth; since in plants the growth of new organs does as a rule not occur along the area of the wound, but at some distance where an old bud existed or a new one is formed. The distance of the growing or regenerating part from the wound may be quite considerable.*

It has been stated that the isolation of the parts is the cause of the new growth following the wound. Thus if a leaf of the tropical plant *Bryophyllum calycinum* is cut off from the plant each of the notches will give rise to a new plant when the leaf is kept in a moist atmosphere. (This is the regular way of propagating this plant.) But no such growth will occur as long as the leaf is kept in connection with the plant (and the latter is normal). Here we seem to have a clear proof of the generally accepted statement that isolation of parts leads to regeneration. The idea seems to be still further corroborated if we cut off a leaf with a piece of the main stem of the plant and suspend it in moist air. In this case no new plants will grow from the notches of the leaf. This again seemingly supports the idea that the separation of the part from the whole is the cause of growth since the leaf attached to a piece of the stem is less isolated than a leaf without any stem. Yet it can be shown that if we diminish the degree of isolation of the leaf still more by leaving it attached to a stem still possessing the opposite leaf the power of the first leaf to form new plants in its notches is enhanced again. The experiment can be

made in the following way. From the same plant let be taken (1) an isolated leaf, (2) a leaf with a piece of stem, (3) a leaf with a piece of stem and the opposite leaf; let all leaves be suspended in a moist chamber with their tips submersed in water. The first and third specimen will form new plants in the submerged parts of their leaves in a comparatively short time, while the second will do so not at all or considerably later than the others.[†] Hence the experiment shows first that complete isolation induces the leaf to form new plants, that less isolation will inhibit this phenomenon, and that still less isolation will again call forth the regeneration. It is therefore plainly impossible to state that isolation is the cause of regeneration.

Those who make such a statement usually assume the existence of inhibiting influences in the plant and explain the effect of isolation on regeneration or growth on the assumption that the isolation frees the part from this inhibiting influence of the whole organism. We should be forced to assume that in the normal *Bryophyllum* there exists an inhibiting influence which prevents the buds in the notches of the leaves from growing, while when the leaf is cut off the notches are released from this inhibiting influence. To this idea we can agree, but then the question arises: What is this inhibiting influence? Thus it is a common experience that in the isolated stem of *Bryophyllum* only the apical buds will grow, while if we cut off the apical buds the next lower buds will grow out, and so on. Hence the growth of the apical buds inhibits the growth of the lower buds. Some more recent authors have suggested that a kind of nervous influence is responsible for this inhibition. But we have already mentioned a number of facts which show

* The process of healing, *i. e.*, of the closing of the wound, should be kept distinct from the phenomena of growth which constitute regeneration.

[†] A full account of these experiments on *Bryophyllum* will be published in the near future.

that in animals substances circulating in the blood influence growth independently of the central nervous system. In *Bryophyllum* I have recently made some experiments which seem to agree with this humoral theory of the control of growth. It can be shown in *Bryophyllum* that if a part *a* inhibits the growth in a part *b*, the presence of *b* favors growth in *a*.

We will illustrate this by two experiments. When we suspend in the moist air of a closed vessel a stem of *Bryophyllum*, whose tip, roots and leaves have been removed, only the buds in the uppermost node will grow into shoots. The growth of the apical shoots inhibits the growth of the lower buds. But if we isolate a node near the apex and suspend it in the same moist chamber, as a rule no regeneration will occur in this node; only if we leave the lower parts of the stem connected with the apical node can the latter regenerate in moist air. Hence the lower part *b*, in which regeneration is suppressed by the topmost part *a*, is necessary or helpful for the regeneration of the top *a*.

The same effect can be produced if, instead of leaving the node near the apex in connection with the lower pieces of the stem, we leave it in connection with one leaf or part of one leaf. In this case also growth of the bud will occur in the moist air. As we have already stated, the leaf is inhibited from forming new shoots in its notches through the connection with the stem. Hence the stem which inhibits the growth of shoots in the leaves is helped by the leaf in its own regeneration.

This seems to agree at first sight with the idea first suggested by Sachs that the specific shoot-forming substances do not exist in sufficient quantity in the topmost part of the stem and that they must be supplied to this piece either by a leaf or by a larger piece of stem. And on the same

principle might be explained the inhibition of the top piece upon the regeneration of the lower nodes. To this assumption the simple objection is possible that a long stem contains material enough to form a dozen shoots or more, as can be shown if the stem is cut into shorter pieces. Each of the lower nodes will in this case form two new shoots. Yet the formation of two shoots at the apical node will prevent the formation of shoots at the lower nodes, although there is enough material to form shoots in every node.

It can be shown that the upper nodes if isolated will promptly form shoots if put into a thin layer of water. Hence the presence of a leaf or of the greater part of a stem enables the upper node to form shoots in moist air either by supplying it with the necessary amount of water or by establishing a flow of material. Where we have a closed circulatory system as in animals we know that the heart action can only maintain a circulation if the blood vessels are filled with blood. The writer is not sufficiently familiar with the circulation in plants, but botanists do not assume the existence of a closed circulatory system. But, however this may be, the presence of a sufficient quantity of water seems to be the prerequisite for a constant flow of substances in the conducting vessels. If we assume that the anatomy of the conducting vessels determines a flow of substances to the apex and second that the buds in that region hold *all* or practically all the formative or specific material which induces growth, the inhibition of growth in the lower buds becomes clear.

Hence we are inclined to explain both the inhibiting effect of an organ *a* upon the regeneration in *b* as well as the accelerating effect of *b* upon *a*, from the following three factors: first, the peculiarities of the anatomy of the conducting vessels in the plant;

second, the necessity of a flow for the transport of substances inducing growth; and third, the retention of these substances (even beyond need) by or near the organs which are first induced to grow or regenerate.

Such a view is supported by the older experiments of the writer on *Tubularia*. *Tubularia* is a hydroid consisting of a hollow stem attached with stolons to a solid substrate, usually piles or rocks, and bearing at its free end a polyp. Only the region behind the hydrant and the tips of the stolons show growth, the cells in the stem do not grow any more. We can, however, induce the cells in any cross section of the stem to grow into a polyp if we cut off the rest of the stem above or beneath it. How does this operation induce growth? The first idea might be that this is due to the wound; the wound, however, can only be the indirect cause, since we perceive such an outgrowth of polyps also from the tips of the uninjured stolons.

I observed that when we cut a piece *ab* from the stem and if we suspend it in sea water, both ends *a* and *b* form polyps, but that the oral end forms its polyps considerably more quickly than the aboral end; and the difference in time may be from one or two weeks to one or two days, according to the temperature and the species used for the experiment. We may, however, induce the aboral end to form its polyps just as quickly as it would form at the oral end if we prevent the formation of the oral polyp by cutting off the oxygen supply at this end. Hence the suppression of the formation of the oral polyp accelerates the formation of the aboral polyp; and, conversely, the formation of the oral polyp retards the formation of the aboral polyp. This might at first appear to be explainable on the assumption that only a limited amount of material for polyp formation was present

in the stem, but this assumption is rendered untenable by the fact that if we cut the stem into a number of pieces each piece will form two polyps, the oral one always more quickly than the aboral one. This shows that the stem has material enough not for two, but, if necessary, for a dozen polyps or more. We understand the facts, however, on the assumption that the material necessary to induce the cells at the front edge to grow into a polyp collects first at this end and is held here; and that only later it can also gather at the opposite end. This is almost the same assumption as that made to explain the phenomena in *Bryophyllum*. But in the case of *Tubularia* the visible phenomena directly support our assumption. I noticed that the formation of a polyp is always preceded by a dense collection of certain pigmented cells from the entoderm which are carried like the blood corpuscles of higher animals in the fluid which circulates through the stem. These red or yellowish cells always collect first at the oral end of a piece cut out from a stem of a *Tubularia*, but if we withdraw the oxygen from this end they collect at once at the aboral end. I mentioned that the tips of stolons may grow out into polyps without a wound. Whenever this happens the formation of a polyp is preceded by a gathering of the red cells in this tip. The question then arises: Why do these red cells gather first at the oral end of a cut piece of the stem? I am not in a position to give a definite answer to this question. I suspect that phenomena of agglutination may play a rôle in this case. All I wanted to indicate was the connection which exists between the transport of special material and the localization and inducement to growth.*

* These older observations of the writer may possibly assume a greater significance in view of the work of Jaa. B. Murphy concerning the rôle of lymphocytes in the prevention of the growth of

I am inclined to see another confirmation of this interpretation in a well-known observation of Morgan on the regeneration of *Planarians*. He found that if a piece be cut from the body at right angles to the longitudinal axis the head will form along the whole cut edge of the piece, while if a piece be cut out obliquely a tiny head will form in the foremost corner of the cut edge. As Bardeen suggested, this would find its explanation on the assumption that the head formation is induced by the collection of certain material which will collect along the whole front when the piece is cut out of the body at right angles, while it is bound to collect in the foremost angle when the piece is cut out obliquely.

VI

When we summarize all the facts we may state that it may be inherent in each cell to grow and divide eternally under suitable conditions; and that we can understand this condition on the simple assumption of the existence of synthetic ferments or synthetic mechanisms in each cell which are formed from the food taken up by the cells. In reality, however, things do not happen in this way in multicellular organisms, and not even in their egg cells. The unfertilized egg can in most cases not grow even under the most favorable conditions and is doomed to die in spite of its potential immortality, unless it is fertilized or treated with the methods of artificial parthenogenesis. The condition of rest or growth depends in this case apparently upon the condition of the cortical layer of the egg and the alteration in the rate of oxidations connected with this condition.

In the body, cells may be at rest or growing, and we do not know whether the conditions which determine rest are identical with

foreign cells in a body, to which reference was made in an earlier part of this paper.

those determining rest in the egg. We know, however, that specific substances circulating in the blood can induce certain resting cells in the body to grow and that these substances differ apparently for different types of cells. It may be that in the body substances antagonistic to these may enforce the inactivity of the cells.

And finally we come to the conclusion that the circulation in animals or the flow of substances in plants is an important factor in the phenomena of cell rest and cell growth, inasmuch as circulation or flow determine or influence the distribution of formed cells or non-formed elements which induce or influence growth. The phenomena of regeneration seem to find to a large extent their explanation in the fact that a wound or mutilation leads to a gathering of formed or non-formed elements in spots where without the mutilation they would or could not have collected.

JACQUES LOEB

THE ROCKEFELLER INSTITUTE FOR
MEDICAL RESEARCH,
NEW YORK

ALASKA SURVEYS AND INVESTIGATIONS

THE United States Geological Survey is dispatching 12 parties to Alaska to continue the systematic surveys and investigations that have been in progress for the last eighteen years. Of these parties three will be sent to southeastern Alaska, one into upper Chitina region, one to Port Valdez; two will work in the Turnagain Arm-Knik region; one will make investigations in the Yukon-Tanana region, and two in the Ruby-Kuskokwim region, and another will traverse the little-known area lying between the Ruby district and the Tanana River. One party will be engaged in general investigations in different parts of the Territory. These parties will sail from Seattle during May, so as to take full advantage of the field season. All the men needed for the work have been engaged, and the pur-

chase of horses, supplies and equipment is well under way.

One of the most important of the undertakings is the extension of the surveys in the Ruby district, on the Yukon, and in the adjacent regions. C. E. Griffin and G. L. Harrington will undertake the surveys in the Ruby district proper, which is now an important gold-placer camp. R. H. Sargent and J. B. Mertie will carry surveys southward to Takotna, on Kuskokwim River. H. M. Eakin will explore the region lying between the mouth of Cosna River, a tributary of the Tanana, and the Ruby district. The only other work in the Yukon basin is that of Eliot Blackwelder, who will make a geologic examination of the White Mountains, southwest of Circle.

The region lying between Knik and Turnagain Arm, tributary to the proposed government railroad, has been only partly mapped, and here both geologic and topographic surveys will be undertaken. The preparation of the topographic base map will be undertaken by one party under the leadership of J. W. Bagley, and the geology and mineral resources will be studied by another party under S. R. Cappe.

B. L. Johnson will complete his detailed study of the geology and mineral resources of the Port Valdez district and will also investigate the mineral resources of other parts of the Prince William Sound region.

Much of the Copper River region has been surveyed in previous years. There still remains, however, the upper Chitina basin, where no geologic work has been done. This work will be undertaken by F. H. Moffit, assisted by R. M. Overbeck.

The detailed topographic mapping adjacent to Juneau, in southeastern Alaska, begun last year, will be continued by D. C. Witherspoon. The base map of this important gold lode district is essential to an exhaustive study of the district which will be undertaken next year.

The mineral resources of the Ketchikan district have been under investigation at different times in the last fifteen years, and the results embodied in reports. Detailed surveys of the

two most important copper-bearing areas of the Ketchikan district have been made. Much of the district has been geologically mapped, but the work is still far from being complete, and the investigation of the geology and mineral resources in this field is to be extended by Theodore Chapin.

The marked industrial advancement in southeastern Alaska has created a great demand for information about the available water-powers, which George H. Canfield has been detailed to investigate. He will also carry on stream gaging in cooperation with the Forest Service.

The hot springs of Alaska are of importance, as many are used as local sanitariums. As no information about them is available, they are to be investigated this summer by G. A. Waring, who will visit the hot springs of Ketchikan and Sitka, in southeastern Alaska; one near Circle and the Baker and Chena hot springs, in the Tanana Valley; and one in Seward Peninsula, about 60 miles north of Nome.

Alfred H. Brooks, geologist in charge of the survey's Alaska investigations, will be engaged in office work until about the end of June. He will then leave for Alaska, and his work will probably include investigations in the Iditarod, Fairbanks and Valdez districts.

AT THE OHIO STATE UNIVERSITY

The following letters have been exchanged between the president of the Ohio State University and the dean of the College of Agriculture:

OHIO STATE UNIVERSITY,
COLUMBUS

My dear Professor Price: Since your remark this morning that you would not remain as professor of rural economics I feel impelled to write you and make an urgent appeal for you to reconsider that decision. My judgment is that you have a quarter of a century of service ahead of you here in a field not well occupied anywhere in the country. You have the esteem and good will as well as the confidence of your colleagues. I can not but feel that you would be sacrificing a highly useful career if you should leave the uni-

versity. It would give me personal satisfaction and pleasure to nominate you at the maximum salary. It would be a great disappointment to me and I think also to your friends if you should persist in your determination to leave the service in the university.

Think this matter over deliberately and let me have assurance of your willingness to remain.

Very cordially,

W. O. THOMPSON

April 21, 1915

April 27, 1915

PRESIDENT W. O. THOMPSON,
Campus.

My dear President Thompson: Your letter of April 21 came to hand and I have delayed answering it until I had time to consult with some men, both on the campus and off of it, who have the welfare of the university at heart, and men in whom I know you have confidence.

I have thought the matter over carefully and what I have to say is said deliberately and without feeling. In answering your urgent appeal to remain in the university I can not refrain from reviewing some of the things that have happened in the college of agriculture during the twelve years that I have been dean.

I came here twelve years ago to fill the position of dean. I had only been out of college six years, most of my associates and colleagues had been my teachers. The college was small, the enrollment was only 243, about one seventh of the total enrollment of the university. The esteem in which the college was held in university circles was not high. Townshend Hall and the old horticultural building represented the material equipment of the college. No winter courses were given, no extension work was done, no farmers' week was held, no three-year courses existed and combination courses with other colleges were unthought of. This year the enrollment in the college is 1,473, nearly one third of the total enrollment of the university. The college of agriculture of Ohio State University is surpassed in enrollment, as reported in a recent number of *SCIENCE*, only by Cornell and the University of Wisconsin. The standards of the college of agriculture have been raised, five buildings have been built, 250 acres of land have been added to the university farm. Most cordial relations exist with all the agricultural organizations of the state, and the work is held in high esteem by the farmers.

All of this progress and development has not

been due to the work of any one man, but rather to the faithful, conscientious work of every one connected with the college, but I insist that in this growth and development I have done my share.

To be summarily demoted without assigning any cause and without explanation, as was done by the recent action of the board of trustees, I resent. I believe that I, my associates and colleagues, and the people of the state are entitled to know why such action was taken.

It is not that I am enamored with administrative work, but one thing for which I have always prided myself has been frank, open dealing with every one and I do not feel that I have been accorded such treatment by you and the board of trustees. However, I could overlook all of that and take up the work of a department if I thought conditions justified it. But I believe that conditions in the university are fundamentally wrong in that the encroachment of the business administration upon the academic has brought about a condition that is rapidly growing intolerable to members of the faculty. Such action as the board has recently taken in reference to me will intimidate your faculty, but it will not give it a sense of permanency that is conducive to constructive, efficient work, neither does it develop the spirit of loyalty.

I appreciate the cordial request that you have made of me to remain in the faculty. But under conditions as they now exist I do not believe it would be wise and very respectfully decline.

It is not without regret and heartaches that I lay down the work of the college in which I have invested my very self for the past twelve years. In retiring I do so without apologies for what has been accomplished during my administration, and I sincerely hope that my successor may have more loyal support from the president and the board of trustees than I have had.

I am,

Very truly yours,

HOMER C. PRICE,

Dean

P. S.—As a matter of information I am referring copies of this correspondence to members of the board of trustees and to the president of the alumni association and am giving it to the press.

THE WASHINGTON UNIVERSITY MEDICAL SCHOOL

On the 29th and 30th of April the new buildings of the Washington University Med-

ical School in St. Louis were dedicated. On the morning of the 29th exercises were held in the Assembly Hall of the school at which the keys of the buildings were formally presented to the acting chancellor of the university by the architect. The visiting delegates were then presented to the chancellor and president of the corporation. The delegates were as follows:

Harvard University: President Abbott Lawrence Lowell.

Yale University: Dean George Blumer.

University of Pennsylvania: Dean William Pepper.

Brown University: Mr. Augustus Levi Abbott.

University of Pittsburgh: Dean Thomas Shaw Arbuthnot.

St. Louis University: Dean Hanau Wolf Loeb.

Medical Corps of the United States Army: Captain Thomas Dupuy Woodson.

Western Reserve University: Dean Carl August Hamann.

Lafayette College: President John Henry MacCracken.

Tulane University of Louisiana: Professor Rudolph Mates.

St. Louis Medical Society: Dr. Robert Emmet Kane.

Knox College: President MacClelland.

University of Michigan: Professor Frederick George Noy.

University of Missouri: Acting-Dean Guy Lincoln Noyes.

University of Bellevue Hospital Medical College: Vice-Dean Samuel Albertus Brown.

New York Academy of Medicine: Dr. Edward Dix Fisher.

Missouri State Medical Association: Dr. Frank Joseph Lutz.

The University of Edinburgh: Professor Lindsay Stephan Milne, University of Kansas.

Central Wesleyan College: President Otto Edward Kriege, Professor Albert William Ebeling.

Detroit College of Medicine and Surgery: Dean B. B. Shurley, Professor Charles Godwin Jennings.

Purdue University: Professor Oliver Perkins Terry.

University of Minnesota: Professor James Edward Moore.

Drury College: President James Gilmer McMurry.

University of Cincinnati: Professor John Ernest Greiwe, Dr. Christian Holmes.

Johns Hopkins University: Professor Theodore Janeway.

Missouri Valley College: Mr. Alphonzo Chase Stewart.

Missouri Botanical Garden: Professor George Thomas Moore.

Leland Stanford Junior University: Dr. Harold Phillip Kuhn.

Dennison University: Dr. E. B. Packer.

University of Kansas: Professor John Sundwall.

Rockefeller Institute for Medical Research: Dr. Simon Flexner.

Memorial Institute for Infectious Diseases and Rush Medical College: Dr. James Bryan Herick.

American College of Surgeons: Dr. Major Gabriel Seelig.

University of Illinois: Dr. Dean D. K. A. Steele, Professor A. C. Eycleshymer.

An address was then made by Dean Opie, of the Medical School, who outlined the early history and reorganization of the school and the ideals which it represents. He was followed by Dr. William H. Welch, of Johns Hopkins, who spoke of the development of clinical teaching in American medical education and of the success which had attended the introduction of full-time clinical teaching at Johns Hopkins, and which is under consideration at Washington University.

After-luncheon addresses were made on the lawn of the medical school by President Lowell, of Harvard, and President Vincent, of the University of Minnesota. Dr. Lowell spoke on the importance of preventive medicine as a public service, and of the necessity of a broad general education as a basis for the training of the physician. Dr. Vincent spoke of the position graduate studies should hold in medical education. Dr. Henry S. Pritchett, president of the Carnegie Foundation for the Advancement of Teaching, the third essayist of the afternoon, was unable to be present and his paper was read by Professor Lowes, of the college faculty. His paper was on "Medical Education in Missouri." After the addresses the guests of the university were entertained at a garden party.

In the evening a banquet was held at the St. Louis Club at which Mr. Robert S. Brookings, president of the corporation of Washington University presided. Responses to toasts were made by President Hill, of the University of Missouri, former Governor David R. Francis, Dr. Abraham Jacobi and Dr. W. H. Howell.

Friday the 30th was known as Alumni Day and in the morning talks were given by Dr. W. T. Porter in behalf of the alumni of the St. Louis Medical College, and Dr. Robert Terry in behalf of the alumni of the Missouri Medical College. These two institutions were united to form the Washington University School in 1899. Dr. Fred T. Murphy then spoke to the alumni in behalf of the medical school faculty.

In the afternoon Dr. Geo. Dock spoke on the relation of the academic hospital to the community. He was followed by Surgeon General W. C. Gorgas who spoke on the eradication of yellow fever and malaria in Havana and in the Canal Zone, and the possibilities that preventive medicine holds for the future.

In the evening academic exercises were held in the university chapel on the university campus followed by a reception in the building of the school of fine arts. The following honorary degrees were given at the exercises:

Doctor of Science: Dr. W. T. Porter; Dr. O. E. Folin, and Dr. Theodore Janeway.

Doctor of Laws: Professor B. H. Chittenden, Dr. W. C. Gorgas, President H. R. Hill, President A. L. Lowell, President George E. Vincent, Dr. F. P. Mall, Dr. Abraham Jacobi, Dr. Simon Flexner, Dr. W. H. Welch, Dr. S. J. Meltzer, Professor W. H. Howell, Dr. Rudolph Mates.

Doctor of Laws (in absentia): Professor Nathaniel Wille, University of Christiania.

Opportunity was provided in the program for the inspection of the laboratories of the medical school and the affiliated Barnes and St. Louis Children's Hospitals. The laboratories were opened in September and consist of two four-story and basement buildings 209 × 56 feet. In the north building are located the administrative offices, library, assembly hall, laboratories of preventive medicine and surgery and the department of anatomy. The

south building is occupied by biological chemistry, physiology and pharmacology. A third building five stories in height and 232 × 60 feet which completes the group is on the hospital lot directly across the street from the other laboratory buildings. The basement and first floors are occupied by the out-patient dispensaries of the hospitals. On the second floor is located the clinical laboratory of the department of medicine, while the department of pathology occupies the third and fourth floors. Animal quarters and runways are provided on the roofs of all the buildings. The three laboratory buildings were erected at a cost of \$1,200,000 which brings the outlay for new buildings for the medical school, including the hospitals, to over \$3,000,000.

One of the interesting features of dedication week was the presentation to the Washington University Medical School of a number of manuscripts and papers of William Beaumont by his granddaughter Miss Irwin. Included among these are the original manuscripts and notes of Beaumont's experiments upon Alexis St. Martin and the agreement entered into by St. Martin to accompany Beaumont, for a period of two years for the purpose of experimentation. Dr. F. J. Lutz spoke of Beaumont as a practitioner and Dr. Joseph Erlanger on Beaumont as an investigator. A room has been set aside in the library of the medical school to house the manuscripts, known as the Beaumont room.

On April 28 Dr. Simon Flexner delivered a popular lecture before the Washington University Association on "The Control of Infective Diseases."

In connection with dedication week of the medical school of Washington University a series of four lectures on "Protein Metabolism" was delivered by Dr. Otto K. Folin. The subjects were as follows:

"The Utilization of Food Protein."

"Tissue Metabolism with Special Reference to Creatinin."

"Protein Metabolism with Special Reference to Uric Acid."

"The Occurrence and Significance of Phenols and Phenol Derivatives in the Urine."

SCIENTIFIC NOTES AND NEWS

For the meeting of the British Association to be held at Manchester from September 7 to September 11 next, under the presidency of Professor Arthur Schuster, Sec. R. S., the following sectional presidents have been appointed: Section A (mathematics and physics), Sir F. D. Dyson; B (chemistry), Professor H. B. Baker; C (geology), Professor Grenville Cole; D (zoology), Professor E. A. Minchin; E (geography), Capt. H. G. Lyons; F (economics), Dr. W. R. Scott; G (engineering), Dr. H. S. Hele-Shaw; H (anthropology), Dr. C. G. Seligman; I (physiology), Professor W. M. Bayliss; K (botany), Professor W. H. Lang; L (education), Mrs. Henry Sidgwick; M (agriculture), Mr. R. H. Rew. Evening discourses will be delivered by Mr. H. W. T. Wager on the "Behavior of Plants in Response to Light," and by Dr. R. A. Sampson, astronomer royal for Scotland.

A BUST of Sir Archibald Geikie will be placed in the Museum of Practical Geology, London, where there are already busts of all previous occupants of the post of director-general of the British Geological Survey and of the museum, as well as of several other distinguished geologists. Sir Archibald Geikie was connected with the survey for nearly forty-six years, during nineteen of which he was director-general. A committee representative of the universities and the principal scientific institutions and societies of the United Kingdom has been formed to carry out the proposal. Contributions for the fund should be made to the honorary treasurer, Mr. J. A. Howe, curator of the Museum of Practical Geology, Jermyn Street, London, S.W.

DR. HENRY S. MUNROE, professor of mining in Columbia University and senior professor in the university, will retire from active service at the close of the present academic year. Professor Munroe began teaching at Columbia in 1877 and became professor in mining in 1891.

On April 30 Professor James Monroe Bartlett had completed thirty years of continuous service as chemist of the Maine Agricultural Experiment Station. This period includes the

entire history of the station itself. In recognition of this unusual length of service in the same institution a reception in Professor Bartlett's honor was held in the station building on the evening mentioned, and he was presented with a commemorative volume. This volume was composed of a series of congratulatory letters from nearly all of the 100 different persons, now living, who have, at one time or another, been associated with Mr. Bartlett in connection with the work of the station.

At the first annual meeting of the District of Columbia Chapter of the Society of the Sigma Xi the following officers were elected: Marcus Benjamin (Columbia), president; Isaac King Phelps (Yale), vice-president; Marcus Ward Lyon, Jr. (Brown), secretary; Daniel Roberts Harper, 3d (Pennsylvania), treasurer; Frederick Leslie Ransome (California) and Cornelius Lott Shear (Nebraska), councillors.

At the annual convocation of the University of Alberta, in Edmonton, on April 28, the honorary degree of D.Sc. was conferred on Mr. W. F. Ferrier, mining engineer and geologist of Toronto. Mr. Ferrier was for nine years an officer of the Geological Survey of Canada. He has made extensive donations to the museum collections at the University of Alberta and has assisted in building up the Geological Museum equipment.

THE Adams prize of the value of about \$1,200 for 1913-14, has been awarded by the University of Cambridge to Mr. G. I. Taylor, Smith's Prizeman in 1910. The subject selected was "The Phenomena of the Disturbed Motion of Fluids, including the Resistances encountered by bodies moving through them."

ACCORDING to a Paris cablegram the French Institute has announced that the Osiris prize, which this year amounts to \$86,600 because no award was made in 1912, has been awarded chiefly for discoveries in medicine. Drs. Chantemesse and Vidal, discoverers of anti-typhoid vaccines, will divide \$10,000, while an equal amount will go to Dr. Vincent, whose researches resulted in the find-

ing of either vaccine. Various ambulances receive \$12,000, and the remainder is placed in reserve.

THE Paris Geographical Society has awarded a gold medal to Dr. J. Scott Keltie for his services to geographical science.

MR. EDWARD W. PARKER, of the United States Geological Survey, for many years the government coal statistician of the division of mineral resources, leaves the government service to accept a responsible position with the anthracite mining companies. Mr. H. D. McCaskey has been appointed chief of the division of mineral resources of the survey to succeed Mr. Parker. Mr. McCaskey brings to this position experience, not only as a geologist of the survey since 1907 and section chief since 1912, but also as a mining engineer in the Philippine Mining Bureau from 1900 to 1903, and as chief of that bureau from 1903 to 1906.

DR. JOHN G. BOWMAN has been appointed director of the American College of Surgeons, founded in 1913, an organization of the surgeons of the United States and Canada. Its purpose is the advancement of the art and science of surgery. The executive offices are at 30 North Michigan Avenue, Chicago.

DR. H. T. SUMMERSGILL, superintendent of the University of California Hospital, has succeeded the late Dr. W. O. Mann, of Boston, as president of the American Hospital Association.

SECRETARY of Agriculture Houston has begun an extensive tour of the national forests to find out for himself to what extent their timber, forage, water power, recreational and agricultural resources are being developed for the public under present methods and to make a study of the administrative problems of the forest service. During May he is visiting the forests in several of the western states.

PROFESSOR KOEPLIN RAVN, an authority on the composition of soils, has arrived here from Copenhagen. He comes at the invitation of the department of agriculture and will lecture in a number of American universities on Danish farming methods.

DR. J. N. ROSE, research associate of the Carnegie Institution, accompanied by Mr. Paul G. Russell, of the United States National Museum, left on May 8 on the steamship *Tennysen*, of the Lamport and Holt Line, for South America. They expect to spend the season in Brazil and Argentina, going under the auspices of the Carnegie Institution of Washington and the New York Botanical Garden for the purpose of studying the cactus deserts of those countries. They plan to send large collections of living cacti to the New York Botanical Garden.

THREE Philadelphia surgeons are soon to leave that city for service in military hospitals of France and England. They are Dr. J. William White, surgeon and trustee of the University of Pennsylvania; Dr. R. Tait McKenzie, head of the university department of physical education, and Dr. James P. Hutchinson, surgeon at the Pennsylvania and Bryn Mawr hospitals. Under Dr. White's charge a corps of physicians and nurses will sail next month for France, where they are to form a unit in the American ambulance hospital at Paris. The operating head of the surgical department of the university corps is to be Dr. Hutchinson.

THE University of Pennsylvania Museum has received a report from Dr. Clarence Fisher, leader of the Eckley B. Coxe, Jr., expedition to Egypt under the auspices of the museum, giving an account of the work accomplished up to the early days of March. Pending the arrangements for a large site for operations, Dr. Fisher was permitted to do excavating at the base of the Second Pyramid of Giza (Gizeh), and has had some excellent results.

THE following men have accepted invitations to carry out investigations in Nela Research Laboratory, National Lamp Works of the General Electric Company, during the coming summer: Dr. W. E. Burge, acting head of the department of physiology, University of Illinois; Dr. A. H. Pfund, associate professor of physics, Johns Hopkins University and Dr. S. O. Mast, associate professor of

zoology, Johns Hopkins University. Mr. B. E. Shackelford, fellow in physics in the University of Chicago, has been appointed Charles F. Brush fellow for the summer of 1915.

THE annual joint meeting of the Phi Beta Kappa and Sigma Xi honorary societies of the University of Pennsylvania was held in Houston Hall on the evening of May 3. Dr. John A. Brashear made the address on the subject of "Great Telescopes of the World and Discoveries made by their Use." An informal reception followed the address. The societies alternate in choosing a speaker, and this year the choice fell to Sigma Xi.

DR. ULRIC DAHLOREN, professor of biology in Princeton University, lectured on May 12 on "The Production of Light by Animals" at the closing exercises of the lecture season of the Wagner Free Institute of Science, Philadelphia.

THE monument to be erected to Cesare Lombroso at Verona, the work of the sculptor Bistolfi, was to have been unveiled at the International Pellagra Congress scheduled for next October. As the congress has been postponed until 1916, the committee in charge of the monument has postponed the dedication.

DR. JAY W. SEAVER, for twenty-five years director of the Yale gymnasium and professor of hygiene in the university, died suddenly from heart disease at Berkeley, Cal., on May 5, at the age of sixty years.

WILLIAM HARLOW REED, curator of the museum and instructor of geology in the University of Wyoming, noted for his collections of vertebrate fossils, died at the age of sixty-seven years on April 24.

MR. DANIEL W. EDGEBOOM, inventor, astronomer and manufacturer of telescopes, has died at his home at Fairfield, Conn., at the age of seventy-five years.

MR. RICHARD LYDEKKER, F.R.S., known for his work and writings on natural science, died on April 16 at the age of sixty-five years.

SIR WILLIAM RICHARD GOWERS, F.R.S., eminent as a specialist on diseases of the nervous system, died on May 4, aged seventy years.

SIR THOMAS SMITH CLOUSTON, a well-known psychiatrist, died at Edinburgh, on April 19, at seventy-five years of age.

DR. M. BERNHARDT, professor of neurology at Berlin, has died at the age of seventy years.

THE death is announced in *Nature* of Mr. J. B. A. L  g  , who made the first tide-predicting machine for Lord Kelvin. He was the constructor of signaling lamps and other apparatus invented by Admiral Sir Percy Scott and used in the navy. Among Mr. L  g  's inventions are horological mechanisms, torpedoes and direct-acting petrol engines.

THE next examination for the medical corps of the navy will be held in Washington, Boston, New York, Philadelphia, Norfolk, Va., Charleston, S. C., Great Lakes (Chicago), Ill., Mare Island, Cal., and Puget Sound, Wash., on or about July 6. Candidates for appointment must be citizens of the United States, between 21 and 30 years of age, and graduates of reputable schools of medicine.

THE U. S. Civil Service Commission announces an examination for metallographist, for men only, to fill a vacancy in this position for service in the Engineer Experiment Station, Naval Academy, Annapolis, Md., at a salary of \$2,500 a year.

THE department of geology of New York University has planned a travel tour for the coming summer which will extend through the western part of the United States and a portion of Alaska. The trip is the outcome of a plan which was formulated by the department of geology two years ago. In the summer session of last year, a course of lectures preparatory to the work that will be taken up this year was given, in order that students might obtain the greatest benefit from the trip. The educational conduct of the tour will be under the direction of Dr. Raymond B. Earle, assistant professor of geology in Hunter College. The director of the department of geology in New York University, Dr. J. Edmund Woodman, will exercise general supervision. The tour will extend from July 2 to August 28 and includes a ten-day visit in Yellowstone Park, a trip to Glacier National Park, an excursion to

Alaska, with an opportunity on the return trip to visit San Francisco, Los Angeles, San Diego, Grand Canyon and the Petrified Forests. Two or three other shorter trips have been provided, one taking in Yellowstone Park and the Glacier National Park, and the other ending with the Yellowstone Park. In the case of students specializing in geology, credit will be given for the trip, under certain conditions, in the various schools of the university.

In connection with the geographical work of the Columbia University summer session, Professor D. W. Johnson will conduct a physiographic excursion in the western United States, next summer. The party will visit the Devil's Tower, Yellowstone National Park, Glacier National Park, Crater Lake, the Yosemite Valley, Royal Gorge of the Arkansas, and the Colorado Springs and Pike's Peak region. It is probable that the new Lassen Peak volcano and the neighboring recent cinder cone will be visited, as well as the Lake Bonneville shorelines and recent fault scarps near Bingham and Provo. While in San Francisco, the party will participate in the excursions of the Geological Society of America to the San Andreas earthquake rift near Point Reyes Station, and the uplift marine terraces at Santa Cruz. Two field courses will be given: a general course on the elements of physical geography and an advanced course on the physiography of the western United States. The courses are open to students and teachers of geology and geography. It is expected that the party will leave New York about the first of July, and be gone two months.

ACCORDING to the American Museum *Journal* Mr. James P. Chapin, of the museum's Congo Expedition, after six years' absence in Africa, has arrived in New York. He brings details of the success of the expedition, not only in the work of a scientific survey but also in having lived without mishap for the extended period of six years amidst the dangers of the equatorial forest and among the negro races of Central Africa—a success due in part to the cordial cooperation of the Belgian gov-

ernment. Mr. Chapin brings with him about one fourth of the expedition's collections. The balance remains in the hands of Mr. Lang, leader of the expedition, who also will come out of the Congo immediately after the final work of packing and shipment is completed. The entire collection numbers some 18,000 specimens of vertebrates alone, 6,000 of which are birds and 5,000 mammals. The specimens are accompanied by some 4,000 pages of descriptive matter and 6,000 photographs. It includes full material and careful studies for museum groups of the okapi, the giant eland and white rhinoceros, besides many specimens of lions, elephants, giraffes, buffaloes, bongos, situtungas, yellow-backed duikers, black forest pigs, giant manis and chimpanzees. The ethnological section of the collection is rich in specimens of native art of the Congo, including several hundred objects of carved ivory, a revelation as to the capacities of the Congo uneducated negro. There are also seventy plaster casts of native faces from the Logo, Azande, Avungura, Mangbetu, Bangba, Anadi, Abarambo, Mayoho, Mabudu, Medje, Mobeli and Pygmy tribes. Each cast is supplemented by a series of photographic studies of the individual.

THE 134th meeting of the Science Club, held March 1, 1915, was addressed by Dr. John F. Hayford, director of the college of engineering, Northwestern University, on "The Surveys and the Decision in the Costa Rica-Panama Boundary Arbitration." An innocuous uncertainty regarding the boundary between Spanish colonies became a serious dispute when these colonies became independent of the mother country and of each other, in 1825. The controversy increased in acuteness as the region in doubt became economically more important. The question, after 75 years of contention, was submitted in 1900 to President Loubet, of France, who settled the boundary on the Pacific slope to the satisfaction of both parties, but from lack of geographical information the award gave more territory on the Atlantic side to Colombia than that country had originally claimed, and de-

fining the boundary in terms incapable of interpretation on the ground. After the separation of Panama from Colombia, the question became more acute and threatened to lead to war, when the matter was again submitted to arbitration, before Chief Justice White, of the United States, with the proviso that an accurate survey should be made. The commission of engineers, two representing the parties to the arbitration, two others appointed by the arbitrator, of whom Dr. Hayford was one, accompanied by twenty-one trained assistants and a large number of laborers and porters made the survey in 1911. The survey was made under the greatest difficulty on account of the dense tropical jungle; absence of roads and trails making it necessary to rely on negro and Indian porters for transportation of supplies; and thickness of forest interfering with seeing. Nevertheless an extensive area was accurately covered, and geographical knowledge secured that is of permanent interest and value. A peak more than 12,000 feet high, hitherto unknown, was discovered, and numerous cartographical errors, including the direction of the drainage of a great area, were rectified. The decision, rendered in 1914, chooses the Sixaola River, its tributary the Yorkina, and the southern watershed of the Sixaola as the boundary, instead of the northern watershed of the Sixaola as awarded by President Loubet, and conforms to the *status quo*, since the customs have been collected at that river, and the subjects of the two countries have advanced to it from each side.

UNIVERSITY AND EDUCATIONAL NEWS

DR. FRANK J. GOODNOW will be installed as president of the Johns Hopkins University on May 20. On the following day the new university buildings at Homewood will be dedicated. President Wilson will make an address; the engineering buildings will be dedicated with an address by General G. W. Goethals, and the academic buildings with an address by Professor H. C. Adams. It is expected that there will be a full attendance of alumni and former students. The committee having charge of arrangements for the inau-

guration and dedication is composed of President Goodnow (chairman), Dr. Ralph V. D. Magoffin (secretary), Dr. Joseph S. Ames, Dr. Murray Peabody Brush, Dr. William B. Clark, Dr. William H. Howell, Dr. Basil L. Gildersleeve, Dr. John H. Latane, Mr. George L. Radcliffe and Dr. C. J. Tilden.

THE Rensselaer Polytechnic Institute announces that Mrs. Russell Sage has given \$100,000 to the school, and Mr. Alfred T. White, of Brooklyn, a graduate, \$50,000. The money is to be used in the erection of dormitories and a dining hall.

A TRUST fund of \$5,000 to be known as the "Edward Tuckerman Fund," designed to increase the interest in the study of botany among the students of Amherst College, has been bequeathed to the college by the late Mrs. S. E. S. Tuckerman, wife of the late Professor Edward Tuckerman. Professor Tuckerman, who was a well known lichenologist, was a member of the Amherst faculty from 1858 until his death in 1886, holding a chair in botany and a lectureship in history.

BROWN UNIVERSITY has received \$7,000 from Mrs. Jesse L. Rosenberger, of Chicago, to endow a lectureship for visiting scholars.

PROFESSOR H. H. NEWMAN, of the department of zoology, University of Chicago, has been appointed dean in the colleges of science of that institution. The duties involve a supervision of students in the biological sciences, especially of those preparing for the study of medicine.

DR. STUART WELLER, of the University of Chicago, has been promoted from an associate professorship to a full professorship in the department of geology.

MARCUS W. LYON, JR., formerly assistant curator, division of mammals, U. S. National Museum, and for the past six years professor of bacteriology at Howard University, has been appointed professor of bacteriology and pathology in the George Washington University.

AT HARVARD UNIVERSITY Dr. Gregory P. Baxter has been promoted to be professor of chemistry, and Dr. John L. Morse to be professor of pediatrics.

DISCUSSION AND CORRESPONDENCE

ISOLATION OF *B. RADICICOLA* FROM SOIL

TO THE EDITOR OF SCIENCE: I am indebted to Dr. F. Löhnis, of the United States Department of Agriculture, for two corrections which I deem it important to make with reference to the paper by Mr. Fowler and myself in SCIENCE of February 12, 1915, on "The Isolation of *Bacillus radiculicola* from the Soil."

The first error is one merely of oversight, and concerns the date in which Beijerinck gave the name *Bacillus radiculicola* to the legume-root nodule organism. That date should of course be 1888 and was put down as 1901 merely through carelessness on my part, and I gladly plead guilty to that.

The second error is that which is partially due to our tentative claim to priority in the direct isolation of *Bacillus radiculicola* from the soil. Dr. Löhnis informs me that claims were made to the isolation directly from the soil of the organism in question by both Beijerinck and by Nobbe, et al. I do not regard the evidence put forward by Beijerinck as conclusive on that point, but there is no question at all that the second investigator named, with his coworkers, has conclusively demonstrated the presence of *Bacillus radiculicola* in the soil and has also, by its isolation in pure culture, been able further to reinoculate plants grown under otherwise sterile conditions. Our neglect to take note of this last-named investigation was due to the manner of indexing pursued in the important abstract journals as well as other scientific journals which gave no useful reference to the work just referred to.

CHAR. B. LIPMAN

A RESEARCH LABORATORY FOR THE PHYSICAL SCIENCES

CONVERSATION with a number of men interested in the biological sciences and who have availed themselves of the opportunity for research work at Woods Hole, Mass., brings out the idea that one great benefit to be derived from the work there is the association with men from all parts of the country. I think all men of science will agree that the great stimulus which comes from the various

meetings of scientific bodies is in the private discussion, which the men have, one with the other, on subjects in which they are particularly interested. Think what it would mean to men in the physical sciences if they could have a laboratory where for two or three months each year, at least, they could meet and carry on some research work and at the same time enjoy the fellowship of men who come from widely separated points but who are interested in their particular field.

I realize that the equipment of a laboratory for physics involves a large outlay of money and transportation of apparatus is not easy, but would the first be impossible? In other words, the object of this note is to raise the question as to whether a laboratory for the physical sciences, similar to that for the biological sciences at Woods Hole, would be a feasible and a desirable project. I believe that many chemists and physicists would be very glad to spend their summer vacation at such a laboratory if it were located, as the one at Woods Hole, where there would be a chance for an outing as well. As at Woods Hole, there would be a resident director and the laboratory would be kept open throughout the year for those who might have a year's leave of absence from their work in teaching.

That men of wealth, who would be interested in building and equipping such a laboratory, might be found does not seem such a vagary in view of what has been accomplished for special laboratories.

S. R. WILLIAMS

PHYSICAL LABORATORY,
OBERLIN COLLEGE

SCIENTIFIC BOOKS

The Salton Sea. A study of the geography, the geology, the floristics and the ecology of a desert basin. By D. T. MACDOUGAL and Collaborators. Carnegie Institution of Washington, Publication 193, 1914. 4to. Pp. 182, with plates, maps and figures in the text.

The making of a lake in a desert basin, whose floor lies below the level of the sea-sur-

face is a circumstance which when within the frontiers of civilization is too rare not to attract wide attention, much intensified by a consequent deflection of a trunk line of railway, the loss of an industry of corporation magnitude and the threatening of areas of cultivation. But in spite of vast antagonism, as measured by money and effort, this is what happened when the waters of the Colorado, first as a tiny stream, but at last as a torrent, entered the Salton Sink through the New River during the few years following 1904. If the lack of foresight which led to this is to be deprecated, it is of no meager congratulation that, precisely as the opportunity was afforded, the Desert Laboratory of the Carnegie Institution of Washington was organized and disposed toward the study of the progress of events by scientific methods. This progress is not completed, nor will be for many years, but the careful planning and continuity of study till the present moment, as witnessed by the volume before us, furnish a sure foundation, under the permanency of a stable organization such as the Carnegie Institution, for a future following of events, so that we may confidently hope at the end to have a more complete and accurate account of the complex interplay of events projected over larger places and times than has yet been produced by science. The case illustrates the necessity of the times. Mutual cooperation of students in diverse fields is becoming more and more imperative, if a satisfying solution of any problem is to be had. For a skilful observation of the Salton Sink a geographer, two geologists, several chemists and various kinds of botanists, probably a working minimum, have been needed.

The work under review may be said to have been begun by the late Professor William Phipps Blake, who, as geologist to the official U. S. Railway Survey which in 1853 had the task of exploring the southern portion of the Sierra Nevada, first comprehended the nature of the Salton basin. An account of the region written by Professor Blake only two years before his death, fittingly introduces the reader to the volume. A strong note of human interest is found in a photograph of Professor

Blake standing on the travertine formation 53 years after the date of his original discovery of it. There is a historic justice in the fact that Professor Blake was permitted to see serious work begun in this desert, for his vast and intimate experience in the southwestern deserts had been but for his death of great value to it.

The dynamic geography of the region is presented by Mr. Godfrey Sykes, who bases his conclusions on the records of the early explorers, tradition and evidence observed *ad hoc*. The Salton Sink represents the northern extremity of the Gulf of California which has been cut off by the formation of a huge natural dam, the ridge of which extends from the Algodones Sandhills to Cerro Prieto. If this is true the major beach line identical with that of the present gulf should be, in view of tidal action, 20 to 30 feet higher than sea-level, and in view of prevailing winds, higher on the northeastern shore than on the opposite, and this Mr. Sykes finds to obtain. Roques's map (1762) indicates that previous to 1762 or thereabout, the Colorado and Gila jointly flowed into an extensive lake, and Indian tradition comports with this. Since 1890 water from the Colorado has at various times found its way into the sink, so that the flooding of recent years was an event following the re-opening of a nearly healed wound. When the flood was dammed, the waters found their way chiefly into Hardy's Colorado, and incidentally the Pattie Basin is receiving a part of the surcharge.

A different view is taken by Mr. E. E. Free, who, in a sketch of the geology and soils, regards the evidence that the basin was never occupied by the sea, any further north at any rate than Carrizo Creek. The absence of marine shells, and presence of millions of fresh-water shells, the occurrence of travertine, the amount of salt deposited and the condition at the present time of the major beach all speak for a genetic precursor of the present waters in a fresh water lake, happily called Blake Sea, which has disappeared in comparatively modern times by evaporation. The formation of the dam which excludes the

waters of the gulf has been built up *pari passu* with a subsidence of the region, bringing the lake floor below sea-level. This view, though championed with moderation, is pretty strongly buttressed by evidence. It is, however, evident that more work may profitably be directed to the problem.

It may be noted in passing that the recent flooding of a portion of the alkaline plays soil has not materially altered its salt content. If leaching out has occurred, the evaporation from the newly exposed lake floor has restored the salts to the soil.

The general position based upon geologic evidence taken by Mr. Free receives additional support from the study of the nature and amount of salinity by Dr. W. H. Ross, who finds that the concentrations and solid components of the Salton Sea to be such as to indicate an originally fresh-water body.

The increasing concentration of these various solutes is found by Dr. A. E. Vinson not to have proceeded at equal rates for all. The potassium-sodium ratio has changed, the former element having remained relatively constant while the concentrations of calcium and magnesium have increased at slower rates. The latter fact is explained by the formation of travertine, the composition of which is largely of the salts (carbonate and sulfate) of those elements.

The following paper on the behavior of organisms in brine, by Professor G. J. Peirce is introduced, aside from its intrinsic merit, evidently by reason of its future relevancy to expected conditions in the Salton Sea, as evaporation proceeds to the production of a maximum concentration of solutes.

For a single instance, it will be important to follow the racial history of the bacteria which are the agents of cellulose hydrolyses in submerged plant tissues, as shown in another paper by Dr. M. A. Brannon to occur as agents of disintegration in the Salton waters. The increasing salinity of these waters offers a succession of barriers beyond which only those forms which possess suitable capabilities of physiological adjustment may pass. It is obviously important to determine these capabilities.

The subjects for Dr. Peirce's study were

found in the salt ponds on San Francisco Bay. A lively impression of the wide adaptability of the living organism is had from the persistence of numerous minute green algae and bacteria which inhabit their waters at whatever concentrations. Of these a chromogenic bacterium responsible for the red coloration of salted codfish, has been isolated and shown to be the cause of the color of the brine and salt. It will come as a shock to those who have supposed a complete preservation to be effected by salting to know that decay may still proceed in fish saturated with salt if exposed to humid air and a moderate temperature. The fluctuations in concentration and composition of the waters of "pickle ponds" and salterns strongly umbrate the theory of balance in solutions, since it is difficult to believe that such relations can here obtain. It was also found that cell division in the protophytes varies inversely to the concentration, being halted by the higher, and stimulated by a lowering.

The deposits of tufa which characterize most markedly a vertical zone 200 feet deep, limited above by the major beach line of Blake Sea, were studied by Dr. J. Claude T. Jones, who shows conclusively its origin to be in the activity of minute algae vegetation (*Calothrix* sp.). By a method not yet understood, certain organisms, *e. g.*, *Chara*, caused the calcium salts to be thrown out of solution in their immediate neighborhood. When the organisms are minute and very numerous a quasi continuous material (sinter) is formed, found however to possess a structure which may be regarded, in a rough sense, as coralline. Imbedded in the tufa of the Salton are found snail shells. Here therefore is further evidence of the fresh-water character of the Blake Sea. The study of tufas on the slopes of ancient lakes must reveal much sure information of their previous history.

Mr. S. B. Parish contributes a paper on the "Plant Ecology and Floristics of the Salton Sink." His long previous acquaintance with the flora of the southwestern deserts places him in a position to offer a particularly complete statistical study of that portion of it included in the region in question. Of 202 species listed, 48 are introduced, and of these it is

important to note that not one has been able to establish itself under constant natural conditions. Of the remaining 131, all but six or seven are more or less widely distributed, chiefly in the surrounding country. But these few appear to be endemic, as they have not been found elsewhere. The suggestion is obvious that these have originated in the sink during comparatively recent times, while it is further pointed out by Dr. MacDougal that other species may have similarly arisen, but have succeeded in passing outwardly beyond the limits of their original home. There is an approach here to something like quantitative relations between geological age and the possible number of new specific origins.

It seems equally probable that other plants, such as the desert palm *Washingtonia filifera* and *Populus Macdougalii*, are to be referred, as to their origin, to comparatively recent dates, and this locality.

The absence of succulent xerophytes, including under this term those with water-storage roots, from this very pronounced desert region is worthy of remark, since, in the minds of many, succulence is regarded as the final expression of desert adaptation. Here the xerophytic shrub with spinose parts and other appropriate characters are the chief perennial inhabitants of the slopes and older strands, while the salt-laden alluvium of the sink-floor bears a zone of the salt-bushes, *Atriplex* spp.

The final paper of the series concerns the movements of the vegetation due to submerision and desiccation and is by Dr. D. T. MacDougal, under whose leadership the whole work has been carried forward. Recognizing the importance of the opportunity to observe the advance of plants upon an immense sterilized area especially in view of the inadequate study or total neglect of analogous earlier opportunities (one thinks of the lost one of Mont Pelée), the lavas of Hawaii, studied by C. N. Forbes excepted, the task was laid out on a comprehensive but workable scale. Sample areas or "belt transects," a mile in width, normal to the beach lines, were chosen, and these, together with sterilized islands, afforded the basis for exhaustive study. This, as the reader will have understood from

what has already been said, embraced not only the vegetation, but the salt content of soil and water and other relations. Usually semi-annual visits were made for the collection of data.

The first half of the paper presents the facts concerning the reoccupation of the strands of six successive years, and a partial study of another, namely, 1913. The earlier strands of Blake Sea, untouched by the recent invasion of waters, afforded a standard for comparison, so that it was possible to measure the rate at which the facies of the new strands took on the same composition as obtains now in the old, relatively static strands. It was observed that the recession of the water was so soon followed by desiccation of the soil that wholly desert conditions were established in the course of a couple of years, and that, in consequence, the introduction of xerophytes identical with those characteristic of the ancient Blake Sea strands had been accomplished in the course of three or four years. The change from close to open formation was similarly rapid.

The transition from one environment to another as the established desert gives way to strand, and the gradual alteration of successive zones correlated with the recession of the water, together with the separation of shore and sterilized islands by extensive water ways, sets up conditions for the study of methods of dissemination and of natural selection as well as reoccupation. It is of more than incidental importance that the reoccupation of islands, and of one shore from another, was among other methods possible chiefly by the flotation of seeds and fruits as proved by many experimental tests. It is clear that in this can be seen no causal relation between the conditions and the "adaptations to flotation." Nature had otherwise been peculiarly far-sighted in furnishing to desert plants not only adaptations in harmony with their immediate surroundings, but with a possibility so remote as the occurrence of a lake! Causal relations are, however, to be seen probably in such characters as reduced superficies, thickened outer tissues, and the like, as a direct result of evaporation, and a number of such correlations have been

or can be made the subject of experimental investigation. To what extent the colloidal substances of cells, such as the mucilage dissolved in the sap, can be made use of, and how this use may be modified by the acid or alkaline content of the disperse medium is at present almost or quite unknown. The great size of tannin idioplasts and the imbibitional avidity of their colloidal content may, it is quite possible, be related, and it is similarly possible that the growth and therefore the size of other cells may depend not only on the "turgor" relations, but even more upon the imbibition pressure exerted upon their walls. The mucilage and other colloidal content of desert succulents *par excellence* may in this light take on greater significance in view of Borowikow's work, cited by MacDougal.

Much more of detail from this collection of papers could be given with more ease than to indicate, without giving an impression of meagerness in the source, the most salient points. Many people untaught in the thought of the scientist have expected vast changes in the surrounding country to follow the flooding of a large desert-inclosed area. The emerged bed of Blake Sea is, however, still a desert, and as measurement and even more superficial observation shows, the evaporation from the many square miles of water surface has had no smallest effect upon any vegetation but that immediately following recession of the water itself. A very short span of time and the desert is restored to its own. But the opportunity of seeing what does happen has fortunately been seized, and we have in this review seen, it is hoped, that a result of signal value has rewarded.

FRANCIS E. LLOYD

MCGILL UNIVERSITY

SCIENTIFIC RESEARCH AND SIGMA XI¹

BEFORE the chapter reports are presented, it is my business for twenty minutes to address you, yours to listen; for Sigma Xi too expects every man to do his duty. We have eaten;

¹ Remarks by the president of the Society of the Sigma Xi at the annual dinner given at the University of Pennsylvania on January 4, 1915.

water has been served; it is a pity that we can not now be merry. For whatever may happen to us, Sigma Xi will not die to-morrow. We have long since passed through the dangerous period of infancy; at the age of twenty-seven the death-rate is but five per thousand. And we surely are a chosen people; like the patriarchs of old, the years of our life are measured not by decenniums but by centuries.

Our first quarter century has indeed been a period of marvelous growth and fruition. As exhibited in the record and history admirably compiled by our secretary, it is one of the fairy tales of science, incredible if it were not true. The beginnings at Cornell University were small, but, like the zygote, they contained the elements which in interaction with a fit environment grew into the great organism, of which each of us is one seven-thousandth. Unlike the individuals of the species to which we belong, our corporate growth does not stop at the age of twenty-five, nor will senility follow fifty years of activity.

In a recent article an eminent American statistician states that 30.7 per cent. of Rhode Island native-born married Protestant mothers are childless. The distinguished dean of a great woman's college within a thousand miles of Philadelphia in a chapel address to the students said that it is not just to charge the decreasing birth rate to the higher education of women; although the college had been established only a few years, forty per cent. of its alumnae were married and sixty per cent. of them had children. When birth-rate statistics are so complicated, it may not be safe to state that we are all the children of Henry Shaler Williams. But this is true, though polyandry appears on the records and we have certainly had polygamous nursing. We may indeed regard our leaders and each of us as somas of the immortal germ plasm, which seeks the light of truth:

That light whose smile kindles the universe,
That beauty in which all things work and move.

As a hand apart from the body is not a hand, as a man apart from other men is not a man, so a scientific man is not conceivable

apart from the long line of scientific worthies, great and small, who have bequeathed to us our present heritage, or from his fellow workers, old and young, without whose sympathy and cooperation no research would be possible. Our society has been founded to personify and promote the spirit of comradeship and zeal which is essential to scientific research. A century earlier, Phi Beta Kappa was established to encourage and reward scholarship in our colleges. It may be desirable to maintain the tradition of classical learning, but as service is better than culture, as the future is of greater concern than the past, so creative science is more than passive scholarship.

The activities of Sigma Xi with which I have indeed least sympathy are those which we have inherited from Phi Beta Kappa. It is a pity that we did not find an honest English name. How many of us know whether *Σίγμα* means companions, or zealous or research? I happen to be one of the small minority of our members who read Greek for professional purposes after leaving college, but I do not know the orthodox way to pronounce our initials. In the presence of these modern Greek mysteries, one feels like the little girl who, being sent to school for the first time, rushed home on hearing the older boys recite: At 'er, beat 'er, jam 'er, eat 'er.

A pendant gold key suitably engraved is too reminiscent of the dueling scars on a face made and marred in Germany, a personally conducted advertisement of a past university student and presumably member of a corps. It has been suggested that the proposed class of associates might be entitled to wear only a smaller key. Why not let the professor carry one three inches long, and if he should become a president, make it a foot long, even though four to one would inadequately represent the difference in eminence and ability to pay for the gold? The badge may be a convenient way to pick up a congenial acquaintance in a smoking car; but would it not be better to wear a more extended label to the effect that I am not only Sigma Xi and Phi Beta Kappa too, but also a teacher of psychology, interested especially in science, education

and democracy, but ready to talk about almost anything except golf and psychical research?

It is better to select and distinguish students for promise or performance in research than for high grades in classes. If interest in research or scholarship can be stimulated by such rewards they are legitimate. But when we embroider with gold braid, we are likely to bind with red tape. I wonder whether a single piece of research work has been conducted or improved because it might lead to election to the National Academy of Sciences or to an honorary university degree. The University of Königsberg has conferred the degree of its four faculties on General von Hindenburg for driving the enemy from the gates of the city, but it may be doubted whether even the doctorate of divinity will be of great assistance to him in checking the invasion. Like old china or other bric-a-brac in a laboratory, all such inherited and artificial distinctions are out of place in a democracy. If members of the National Academy received a salary for useful services, or if membership in Sigma Xi enabled students to go on with their researches then the election would be useful and desirable. It would from my point of view be better if membership in Sigma Xi depended on the option and efforts of the student and the scientific man, such as attendance at meetings and the presentation of a paper.

Even the separation of the academic sheep from the philistine goats does not seem to be a desirable segregation. A college and university education is certainly at present the gateway through which they must pass who wish to follow the paths of scientific research. But from some points of view, this is an evil necessity rather than an ideal condition. It is costly in money and precious years, in initiative and originality. The two greatest scientific men whom we have known, Simon Newcomb and William James, did not enjoy or suffer the orthodox college or university education; the same is true of the two living Americans responsible for the most important applications of science—Mr. Edison and Mr. Bell. If two academic degrees were required—four years of college culture and four years

of professional training—before the poet, the novelist, the musician, or the artist could become productive, what would be left of the literature and the art of the world? It is a system of privilege when only those can enter the professions whose parents are able to support them to the age of twenty-seven years; it postpones too long family duties and civic responsibility, and those who travel long over well-worn ways may accumulate baggage and habits which burden rather than help the exploration of new territory.

Your to-night's figurehead has been accused of being habitually "agin the administrashun," but in intention at least he is radical only as to ends, while reasonably conservative as to means. Our Society of Sigma Xi, like the university of which it is a part and much else that is best in our civilization, is a heritage handed down to us from other days and other ways, only partly adjusted to a democracy in the twentieth century. Institutions and customs should not be bent until they break; they should be permitted to reach toward the light by their own gradual growth. We can not live in a true democracy until it exists, and in the meanwhile we must do the best we can with our inherited institutions and human nature. Our society has in several directions led the way—in placing research before high grades in class work, in uniting those showing the beginnings of aptitude for research work with productive scientific men, in emphasizing and promoting the comradeship and common interests of scientific workers, in arranging scientific meetings and lectures to which all are welcome, in putting applied science on terms of equality with other research, lastly and chiefly in being one of the active agencies contributing to scientific advance.

It is anti-democratic to hold that culture is precious because it can be attained only by those having wealth and leisure, that science is noble only when it is useless. The mathematician who thanked God that his geometry was a virgin that had never been prostituted by being put to any use did not stay in America longer than he could help. Pure science may proceed on a long orbit, but it can not

go off on a tangent to the real things of life. Our society has served both science and democracy by placing engineering on terms of equality with other sciences. The distinction is not between scientific discovery and practical applications, but between the discovery of new truths or new ways of doing things and the repetition of those already learned; not between the pathologist who studies diseases and the one who finds cures, but between the experimental pathologist and the routine practising physician; not between the engineer who builds bridges and the one who writes about bridges, but between the scientific man who devises new methods and the builder who copies old models. Adopting what Francis Bacon wrote in another connection:

These two subjects, which on account of the narrowness of men's views and the traditions of professors have been so long discovered, are, in fact, one and the same thing, and compose one body of science.

And most of all, this Society of the Sigma Xi has served democracy and science by emphasizing research work at the outset of the student's career and as the essential life work of each of our members. It is our business to promote scientific research by every method and by every motive. A correct statement of the economic value of science to society would at first sight seem incredible. It is safe to say that the applications of science have quadrupled the productivity of labor and doubled the length of human life, though it is not possible to give the exact period from which this result is reckoned. The writer would guess that so much progress has been made within from one hundred to one hundred and fifty years. In some kinds of work, as in the transportation of freight over land and some kinds of manufacturing, the efficiency of labor has been increased a hundredfold; in others, as in agriculture, it may have been only doubled. In the period during which the efficiency of labor has been quadrupled by modern science, the annual production of wealth in the civilized world has perhaps been increased a hundred billion dollars, representing

a capital sum of two thousand billion dollars.³ A great part of this advance is due to a few men, probably one half of it to, at most, 10,000 men. The value of each of these men to the world has been a hundred million dollars; they have been men not abler nor more productive on the average than the upper five hundred of our leading American men of science.

So far from being exaggerated this valuation of science and of scientific men neglects the decrease of disease and suffering, the increased length of life and the vast number of human beings for whom life has been made possible. It can not take account of the moral, intellectual, political and social changes wrought by science and its applications. Science has made democracy possible and has given us as much of it as we have. The applications of science have abolished the necessity of continuous manual labor from childhood to old age, they have made feasible universal education, equality of opportunity and equality of privilege, they have banished legal slavery, they have partly done away with the labor of children and the subjection of women. Science has given us freedom in the moral as well as in the material world, freedom from ignorance, superstition and unreason, the means of learning the truth and the right to tell it.

The service of science for the world is by no means complete. The productivity of labor can be again doubled by further scientific discovery; it can be more than doubled by the selection of the right men for the work they do and by correct methods of work. The value of wealth can be doubled by its proper distribution and use. Warfare, preventable disease and vice, waste and display, the futile complications of civilization, consume one half of all the wealth that is produced. We do not know the conditions of happiness and real wel-

fare or how they are to be attained. Science should continue to press to the limit economy of production and the conservation of health and life; at the same time it should increasingly direct its methods to the control of human conduct.

Suddenly, out of its stale and drowsy lair, the lair of slaves,

Like lightning it leapt forth half startled at itself, Its feet upon the ashes and the rage, its hands tight to the throats of kings.

On us here in America there has been thrust the duty and the privilege to carry forward the flickering torch of science and of civilization. Our society of the Sigma Xi and each of us have indeed great opportunity and great responsibility.

J. McKEEN CATTELL

RADIUM FERTILIZER IN FIELD TESTS

WITH the discovery of radio-activity by Becquerel, in 1896, and of radium itself by M. and Mme. Curie, in 1898, science revealed a property of matter and a source of energy hitherto unknown; and the facts already established, the predictions or claims made, and the general interest in the subject seemed to justify an investigation under field conditions of the possible value of radium as a fertilizer, or of radio-activity as a crop stimulant.

While possessing most of the properties of an element, reacting chemically very similarly to the element barium, radium also has the remarkable property of continuous disintegration, by continuous emanation of particles, which is accompanied by radiation of energy, called radio-activity.

Investigations show that one gram of radium emits enough heat to raise 118 grams of water one degree centigrade in one hour, or 118 calories, and indicate about enough total energy to decompose one gram of water into hydrogen and oxygen every twenty-four hours, equivalent to more than 8,800 calories, or nearly 160 calories per hour. This radiation continues hour after hour with gradual reduction to $\frac{1}{2}$ the quantity in about 1,760 years, to $\frac{1}{4}$ in

³ This enormous figure is based on the assumption that there are 25,000,000 people in the United States, whose productive work is worth on the average \$1,000 a year and six times as many in the civilized world who earn on the average half so much, with enough left over to balance the earnings of 100 years ago.

3,520 years, to $\frac{1}{2}$ in 5,280 years, and so on. Thus the total energy ultimately evolved from 1 pound of radium is equivalent to more than 70,000 twenty-four-hour days of horse-power.

Many experiments have been made to ascertain the effect of radio-activity on plant growth; and in general a distinct influence is noted, although some experimenters report negative results.

Gager¹ in summarizing his investigations states that radium acts under certain conditions as a stimulus to physiological processes, but, if used in too great strength or for too long a period, it may retard development or even kill the plant.

Fabre² noted some beneficial effects from emanations, using a concentration of $1\frac{1}{2}$ micro-curies³ for each 2 liters of air, but injury from greater strength.

Stoklasa⁴ found that radium emanations promoted germination of seeds and accelerated the growth of plants to a considerable extent. From earlier experiments he has reported increased fixation of nitrogen by bacteria.

In the spring of 1913, through the kindness of the Standard Chemical Company of Pittsburgh the University of Illinois Agricultural Experiment Station was enabled to begin a series of field experiments with radium as a fertilizer or crop stimulant. The company was deeply interested in having the experiments conducted, and the radium salts furnished to us were prepared under the direction of Doctor Otto Brill and Doctor Charles H. Viol, of the radium research laboratory of the Standard Chemical Company, the quality and strength of the preparations being thus assured.

The value of radium is about \$100 per milligram and in order that the field investigation might have a direct relation to practical agri-

culture, the radium was used at three rates of application, costing, respectively, \$1, \$10 and \$100 per acre; or in amounts of .01 milligram, .1 milligram and 1 milligram of radium per acre. If the effect of the application should be marked and permanent, even the initial expense of \$100 per acre might be desirable.

The fields selected for these experiments were the north division of Series 200 and the south division of Series 600 of the agronomy plots on the South Farm of the University of Illinois. Each of these fields includes 144 fortieth-acre plots, two rods square, besides some divisions and border strips, making the field sixteen rods wide east and west, and thirty-eight rods long north and south.

On Series 200 and on the west part of Series 600, the radium was applied in a solution of radium barium chloride diluted with distilled water, the check plots receiving the same quantity of distilled water without radium. On the east part of Series 600 solid radium barium sulfates were applied, after diluting by thoroughly mixing and pulverizing with dry soil from the field, the check plot receiving the same weight of soil without radium. The pulverized soil was applied with a force-feed grain drill, and the solutions with an Aspinwall barrel sprayer.

The amount of radio-active substances applied in these tests was purposely made small, in order to avoid any appreciable effect of the substance other than that due to radio-activity. It is conceivable that some effect might be obtained from the application of 100 or 200 pounds per acre of mineral salts. The amount in the case of the heaviest applications was less than five pound of total salts per acre.

On both fields corn was grown in 1913 and soy beans in 1914. Owing to other experimental work involving some variations in planting, only part of Series 600 furnished comparable data in 1913, only twenty-four separate trials being provided. The work of the two years,⁵ however, comprised 144 tests with corn and 240 tests with soy beans. Aside

Series 600 possesses an unusually satisfactory degree of uniformity; but on Series 200 there are some topographic variations which influence the rapidity of "run-off" or absorption of rain, and in very dry seasons, with occasional dashing showers, when moisture is a factor of great importance, these variations appear in the crop yields. From April 11 to September 11, a period of five months, the total rainfall in 1913 was only 5.87 inches. Under these adverse conditions, even the average results from Series 200 are not considered trustworthy, notwithstanding the large number of separate trials making the averages. Even from the general averages .01 milligram of radium appears to have decreased the yield by 1 bushel on the west part and to have made 2.3 bushels increase on the east part of the field. Again, increasing the cost of radium from \$1 to \$10 per acre appears to have increased the yield of corn by 3.6 bushels on the west part and by only .7 bushel on the east part; and the further increase of \$90 shows apparent gains of 1.3 bushels on the west and .5 bushel on the east part of this field. Of course no conclusions should be drawn from such discordant plus and minus results.

The results with soy beans on Series 200 in 1914 agree within narrow limits in showing no benefit from the radium applied the year before, the west half of the field giving slightly

smaller and the east half slightly larger average yield where radium was added than on the check plots.

On Series 600 the average yields of corn in 1913 were slightly larger with two kernels per hill and slightly smaller with three kernels per hill where radium was applied, but the apparent gains and losses are all well within the experimental error of plot variation, and the general average indicates no effect from the radium. The yields of soy-bean seed on the north half of this field in 1914 likewise reveal no influence of radium, all rates of application indicating as an average slight decreases for radium on the west side and slight increases on the east side of the field. With the soy-bean hay the six general averages show no effect from radium, four results being slightly below the checks and the other two slightly above.

Thus from the two years' work we have six trustworthy average results with corn, three "for" and three "against" radium, and we have eighteen averages with soy beans, nine "for" and nine "against" radium. In all of these trials the average variation from the checks is so slight and so evenly distributed, "for" and "against," as to lead only to the conclusion that radium applied at a cost of \$1, \$10 or \$100 per acre has produced no effect upon the crop yields either the first or second season.

Radium, with all its wonderful energy, is found upon careful analysis of the known facts, to afford no foundation for reasonable expectation of increased crop yields, when financial possibilities are considered. The rate of application mentioned by Fabre, on the basis of $1\frac{1}{2}$ microcuries for each space four inches square and eight inches high, would cost about \$58,800 per acre at present prices for radium.

It is true that the total ultimate energy developed in 1,760 years from 1 pound of radium will be equivalent to 35,000 horse-power days of 24 hours each; but when the time is reduced to 100 days of good crop-growing weather, and the amount of radium reduced to 10 milligrams, or to a cost of \$1,000 per acre, then the energy emitted from the radium

for the possible benefit of an acre of corn during the crop season would be equivalent to 1 horse-power for 22 seconds; and the heat evolved by \$1,000 worth of radium on an acre of land in 100 days would be less than the heat received from the sun on one square foot in 30 seconds.

SPECIAL ARTICLES

NEW REPTILES FROM THE TRIAS OF ARIZONA AND NEW MEXICO

BEGINNING the later part of March, 1914, the University of Wisconsin paleontological expedition spent two months in Arizona and New Mexico collecting Triassic vertebrates. The time was divided chiefly between two localities, Wingate, New Mexico, nine miles east of Gallup, and along the Little Colorado River some fifty miles northeast of Flagstaff, Arizona. In both localities material was collected which should add substantially to our knowledge of the Triassic vertebrate faunas of the west.

Conspicuous among the collections are Phytosaur remains of various types. One nearly complete skull, apparently the largest yet discovered, will probably prove to be a new form.

One of the most interesting finds from the Wingate region is that of a nearly complete pelvic girdle of distinctive form. The sacrum consists of two closely united vertebrae with moderately biconcave centra. The neural arches are massive and are surmounted by stout, comparatively short spines with considerably expanded tops. The sacral ribs unite broadly with the arch and centrum, each rib being supported by a single vertebra. Distally the ribs are greatly expanded in an antero-posterior direction and are considerably thickened below and apparently down curved along the inner side of the ilium.

The upper portion of the ilium is expanded both laterally and in an antero-posterior direction into a broad, horizontal shelf. The ischia meet along the median line in a trough-like union that extends back in a hori-

zontal tongue-shaped process. The pubes take a comparatively small part in the floor of the pelvic opening as the lower anterior portion of these elements extends directly down in a broad plate-like expansion at right angles to the vertebral column. The lower outer corner of the pubic expansion is swollen into a foot-like process, possibly to bear a portion of the weight of the creature when at rest.

All three elements enter the imperforate acetabulum in a firm union. The acetabulum is large and deeply concave and set off by a prominent raised boundary. It is directed out and down and considerably back. The girdle measures about 450 mm. from the top of the sacral spines to the lower border of the plate-like expansion of the pubis. The greatest width, at the lateral expansion of the upper portion of the ilia, is approximately 370 mm.

The massive construction of the girdle has suggested the name *Acompsosaurus wingatensis* for this new form. It is to be hoped that other material in the collections will add a knowledge of other parts of the skeleton. Figures and a more complete description of *Acompsosaurus wingatensis* will follow in another place.

SOCIETIES AND ACADEMIES

THE BIOLOGICAL SOCIETY OF WASHINGTON

THE 539th meeting of the society was held in the Assembly Hall of the Cosmos Club, Saturday, April 3, 1915, called to order by President Bartsch at 8 P.M., with 65 persons present.

On recommendation of the council, Mr. Ben Miller was elected to active membership.

Under heading Brief Notes, Dr. L. O. Howard called attention to a wasps' nest he had lately seen which was marked by a conspicuous blue streak. In making this nest the wasps had evidently made the blue streaked part out of a blue building paper, instead of making their pulp from the natural wood. Messrs. Bartsch and Lyon referred to the red-headed woodpeckers in the grounds of Freedmen's Hospital, stating that a few birds had remained during the winter of 1914-15, though none had wintered during 1913-1914. The species is abundant in the hospital grounds this spring. Messrs. Bartsch and Bailey

commented upon the scratching of the gray squirrels in the city parks, which Mr. Bailey said was due to infestation with fleas from their winter boxes. Suitable insect powder placed in the boxes would drive out the fleas, but was not relied by the squirrels.

The first paper on the regular program was by Dr. A. H. Wright, of Cornell University, "The Snakes and Lizards of Okefenokee Swamp." Dr. Wright said:

Seven snakes of the dry open sandy fields or pine forests of southeastern U. S. were absent on the Okefenokee Swamp islands. None of the truly Floridan ophiidians and saurians were represented. Some forms occurred on the outskirts of the swamp but were wholly wanting within the swamp. The 21 species of snakes and 6 lizards were very variable in scutellation and coloration. Whether the restricted quarters and the incessant warfare and struggle for place caused the wide range of variation is not yet answerable. We had expected to find fixed peculiar stable races or subspecies because of the isolated nature of some of the islands, but segregation has not yet placed a local stamp on any of the reptilian forms. The swamp is the common source of the Atlantic coastal stream, the St. Mary's, and the Gulf affluent, the Suwannee. This factor may have had its influence on the turtles and possibly on the snakes and lizards. The swamp does not appear to be a barrier or boundary line between two decided faunal areas. It is rather a melting pot for many of the supposed cardinal characters of distinction in snakes and lizards.

Some of the interesting systematic observations are: the nontrustworthiness of the temporal scutellation and coloration in the *Elaphe* group; the need of further study in the *Tropidonotus fasciatus* assemblage; the presence of the *Ocoella clapsoides* and the *Lampropeltis doliaetus coccineus* characters in one and the same specimen; the reduction of *Diadophis amabilis stictogenys* to *D. punctatus*; the non-recognition of *Ophisaurus ventralis compressus*; the presence of white-bellied adults and young of *Farancia*; the possibility of *Heterodon niger* as an end phase of coloration and a query as to the loss of the axzygous in *Heterodon browni*; the overlapping in scale rows and ocular formulae in *Storeria occipitomaculata* and *S. dekayi*; the fact that no two heads of the *Sceloporus undulatus* specimens had the same plate arrangement; and the unreliability of the mental characters in *Plestiodon*, our specimens of *P. quinquevittatus* falling into two of Cope's major groups, if determined on mental scutellation.

Dr. Wright's paper was illustrated by lantern slides showing views of the swamp, of its reptile inhabitants, and of the variations found in certain of the species. His communication was discussed by the chair and Messrs. Wm. Palmer and Hugh Smith.

The second and last paper of the program was

by Dr. Arthur A. Allen, of Cornell University, "The Birds of a Cat-tail Marsh."

Observations on the food, nesting habits and structure of marsh birds showing the limitations of specialized species as to food, distribution and power of adaptability and the dominance of generalized forms were made.

Specialization in birds goes hand in hand with a high development of the instincts, but with a low degree of intelligence and little adaptability. Generalization of structure, on the other hand, occurs with a weaker development of the instincts, greater intelligence and greater adaptability. The generalized, adaptable species persist through the ages, while the specialized, non-adaptable are first to go. This is seen in the birds of a cat-tail marsh.

Seven stages are recognized in the formation of a marsh, represented in the mature marsh by zones of typical vegetation or plant associations, these associations following one another in regular succession. Similar associations and successions can be recognized among the birds if we group them according to their nesting range in the marsh. Most species are not confined to one association, although reaching their maximum of abundance in it. The generalized, adaptable species have the widest range.

The various associations with their typical birds follow:

- I. The Open-water Association; important in supplying forage, but with no nesting birds.
- II. The Shoreline Association, with the pied-billed grebe, a specialized non-adaptable species.
- III. The Cat-tail Association, with the least bittern, coot, Florida gallinule, Virginia rail, Sora rail and red-winged blackbird, finding optimum conditions.
- IV. The Sedge Association, with the long-billed marsh wren, bittern, swamp sparrow, short-billed marsh wren, and marsh hawk.
- V. The Grass Association, with the song sparrow and Maryland yellowthroat.
- VI. The Alder-Willow Association, with the green heron and alder flycatcher.
- VII. The Maple-Elm Association, with the black-crowned night heron, and great blue heron of the marsh birds and a great variety woodland species.

Of all these species the one most generalized in habit and structure is the red-winged blackbird. It, too, is the most adaptable and is the dominant species in the marsh.

Dr. Allen's paper was illustrated by numerous lantern slides from photographs of the marsh, its bird inhabitants, and their homes, and by motion pictures of the least bittern and of the canvas-back and other ducks.

Dr. Allen's paper was discussed by Dr. L. O. Howard.

The society adjourned at 10.15 P.M.

REMINISCENCES OF THE WOODS HOLE LABORATORY OF THE BUREAU OF FISHERIES, 1882-89¹

On February 9, 1871, a law was passed by Congress which directed the President to appoint a man of approved scientific and practical knowledge of fish and fisheries, to be chosen from among the civil officers of the government, who was to serve as U. S. Commissioner of Fish and Fisheries without additional salary.

This act virtually defined Spencer F. Baird, secretary of the Smithsonian Institution, who thereupon was appointed commissioner by the President. The commissioner was clothed with unusual powers; for the act instructed the heads of the various executive departments to render the commissioner such assistance as might lie in their power. Frequent acknowledgments of the cooperation of the departments of the treasury, war, interior and navy are found in the earlier reports of the Fish Commission.

The immediate problem before the commissioner was: An inquiry into the decrease of food fishes. It is interesting to note that Professor Baird chose Woods Hole as the place for beginning research on this problem. That was in the summer of 1871. Those associated with him were Professors A. E. Verrill, Theodore N. Gill and Sydney I. Smith.

The headquarters in 1872 were at Eastport, Maine; in 1873 at Portland, Maine; in 1874 at Noank, Connecticut; in 1875 again at Woods Hole. During the year

¹ A lecture delivered before the Marine Biological Laboratory, Woods Hole, Mass., August 7, 1914.

MS. intended for publication and books, etc., intended for review should be sent to Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

1876 no active field operations were carried on by Professor Baird on account of duties connected with the superintendency of the government exhibit at Philadelphia. In the report for 1876, however, the following statement is made:

The laboratory at Woods Hole was opened . . . for investigators, to whom every facility and assistance was furnished by Vinal N. Edwards in charge of the station.

The first part of the summer of 1877 was spent at Salem, Mass. In August the party proceeded to Halifax, N. S., where a second station for the summer was formed. Among the assistants of Professor Verrill that year was E. B. Wilson. (It is needless to inform this audience that E. B. Wilson has since been promoted.) In 1878 the laboratory was on Fort Hill at the mouth of Gloucester Harbor; in 1879 at Provincetown, Mass., and in 1880 at Newport, R. I. In 1881 Woods Hole was again chosen as the center of scientific operations. In the report for that year Professor Baird speaks of the advantages of the place as a permanent sea-coast station of the U. S. Fish Commission. In the report for 1882 the reasons for choosing Woods Hole as a permanent station are given. After speaking of the experience at Gloucester the report continues:

A totally different condition of things was found at Woods Hole where the water is exceptionally pure and free from sediment, and where a strong tide rushing through the Woods Hole passage keeps the water in a state of healthy oxygenation specially favorable for biological research of every kind and description. The entire absence of sewage owing to the remoteness of large towns, as well as the absence of large rivers tending to reduce the salinity of the water, constituted a strong argument in its favor, and this station was finally fixed upon for the purpose in question.

In the report for 1875, published in 1878, one finds the spelling of the name of the station changed from Woods Hole to Woods Holl. This change was made in

conformity with a similar change made by the Post Office Department. An ingenious argument for this unusual way of spelling hole will be found in a small pamphlet written by the late Joseph Fay. It should be stated, in justice to the author of the pamphlet, that his contention was that the word in question was really the Norwegian word *holl*, meaning a hill, but pronounced hole.

In this connection it is proper to mention the fact that this same Joseph Fay gave to the U. S. government the waterfront extending from what is now the property of the Marine Biological Laboratory to what is now called Penzance, but then was without a name, if one will except the obvious epithets which were liberally applied to the locality by the residents of Great Harbor whenever the wind was from the northwest, for there was situated a large fertilizer establishment, known locally as the "Guano Works." Among material collected at Woods Hole in 1882, I still have a considerable number of goose-barnacles which I scraped from an Italian bark, 90 days out from the Mediterranean, then tied up at the wharf of the "Guano Works" and unloading her cargo of sulphur.

Prior to 1877 the tug *Blue Light* was detailed by the Navy for the use of the Fish Commission. A larger tug, the *Speedwell*, was detailed in 1877. In the year 1880 the *Fish Hawk*, which had just been built, was used in exploring the Gulf Stream and its fauna, especially in connection with the distribution of the tile-fish. In 1883 the *Albatross*, a ship especially designed for deep-sea work, was completed and placed in commission.

Professor Baird early inaugurated the policy of naming a vessel that was propelled by its own power for some bird. A sailing-vessel was given the name of a water mammal, while rowboats were given the names

of fish. With the installation of auxiliary motors in such craft as the *Grampus* and *Dolphin* the taxonomy of the Fish Commission's flotilla is not without its difficulties.

When Professor Baird was laying his plans for a permanent laboratory he was in much doubt as to his ability to induce Congress to make an appropriation for such purpose. Assured of a location for the laboratory, through the public spirit of Joseph Fay, he conceived the idea of having universities and colleges cooperate in the building of a laboratory. To this end he prepared articles of agreement whereby an institution by contributing the sum of one thousand dollars would have the right in perpetuity to the use of a table in the laboratory. This offer was open for but a short time, as Congress, having had experimental proof of the administrative ability and probity of Professor Baird, made the necessary appropriation for the construction of the laboratory. Before the offer was withdrawn, Professor Alexander Agassiz had subscribed for a number of tables, four, I think, for the use of Harvard University. My recollection is that one table was subscribed for by Princeton, one by Williams, and one by some other institution. It is largely owing to this plan that a succession of graduate students has occupied tables in the laboratory of the Fish Commission since 1885. These students brought with them new ideas and methods and inspiration that have been important factors in the usefulness of the laboratory.

Upon the death of Professor Baird, in 1887, G. Brown Goode was made commissioner pro tempore. He, indeed, was the logical successor of Professor Baird, but preferred to remain at the head of the National Museum. In the meantime the law had been changed, so far as to make the office of commissioner a salaried office. Colonel Marshall McDonald was appointed

commissioner in 1888. He served until his death in 1895. Captain J. J. Brice of the Navy was made commissioner in 1896, Mr. Herbert A. Gill being acting commissioner in the interval. Captain Brice served until 1898, when he was succeeded by George M. Bowers, who served for nearly as long a term as that of Professor Baird's. During Mr. Bowers's term of office the commission ceased to be independent. It became a bureau, first in the Department of Commerce and Labor, then in the Department of Commerce. In 1913 Dr. Hugh M. Smith, long associated with the commission, and for some years deputy commissioner, succeeded Commissioner Bowers, and is the present commissioner.

In all the time from 1871 to the present, with the exception of the brief administration of Captain Brice, every encouragement has been given to scientific investigation at the Woods Hole Laboratory of the Fish Commission. Of the laboratory during the administration of Captain Brice I have no personal knowledge. I have been informed, however, that then, for a time, at least, scientific work was virtually suspended, and would have ceased entirely but for the vigorous insistence of Professor Alexander Agassiz on the right of Harvard University to occupy tables in the laboratory. Thanks, therefore, to these compacts, which, I think, Professor Baird somewhat regretted had been entered into, the work of scientific investigation at the Woods Hole Laboratory of the Fish Commission has not been seriously interrupted from its inception under Professor Baird to the present time.

Prior to 1885 the laboratory was on the lighthouse wharf on Little Harbor in the two-story building which had been refitted, the second story added, with outside stairs on the north side. Professor Baird lived in the house which stands just east of the one occupied by Miss Sarah Fay. As I re-

member the house then it had a good-sized porch in front. The offices of the clerical force of the commission were in a house known as the Gardiner house, which stood about where the entrance to the rose garden now is. This house has since been removed. The house occupied by Professor Baird also accommodated the mess, which was made up of the scientific workers and the clerical force. The various members of the party roomed at private houses in the village. For example, in the summers of 1882, 1883 and a part of 1884, four of us younger men had rooms on the third floor of what was then, and still is, the rectory. From the windows of these rooms are to be had some of the most charming views of these beautiful shores.

The residence building was first occupied early in August, 1884. It then accommodated Professor Baird's family, the scientific staff and the office force. The dining-room easily accommodated the entire company, about 30, which constituted a real family, of which Professor Baird was the head. He and his wife and daughter, and some of the older members of the scientific corps, with their wives, occupied one table, the other scientific workers filled another table, and the clerical force a third. The parlor of the residence made a general meeting-place where all the members of the family were accustomed to assemble in the evenings. Although the habit of working in the laboratory at night still continued, members of the laboratory force were in frequent attendance at these family gatherings. In the summer of 1886 we rented a piano and installed it in the parlor, where some pleasant hours were spent in singing, and, on a few occasions, others were invited in and there was a little dancing.

Work on the new laboratory building was in progress during the summer of 1884. A picture which hangs on the south

wall of the porch room of the residence gives a view of the locality where the Fish Commission buildings now stand, as it appeared in 1882. During the dredging operations that preceded the construction of the sea wall that encloses the basins we were frequently detailed to make collections of the mud-inhabiting forms that were brought up by the dredge.

The laboratory in 1882 was, as has been stated, on the lighthouse wharf on Little Harbor. Ordinarily the day's work began before 9 o'clock and continued until 10 or 11 o'clock at night. As Professor Verrill's assistant my work in 1882 and 1883 was especially directed to the group of Annelids. Later I was promoted to investigate the ancient and, to some minds, dishonorable, order of Cestodes and their kindred.

In those years there was not much systematic collecting done along shore and in shallow water, except for certain groups and localities. A good deal of time was taken up in the collection and study of surface material, but the chief interest centered about the trips of the *Fish Hawk* to the Gulf Stream. There were other shorter trips for the purpose of exploring some shallow-water localities that were very full of interest to a beginner. The first trip which I made was one to the northward where the dredging operations began off Chatham and continued to Provincetown. It was on this trip that I saw for the first time, in a living state, some particularly large sea-anemones, and the many-armed serpent-star *Astrophyton*. At Provincetown there was at that time an establishment on the point where whale oil was tried out, the whales being taken offshore and brought in to the try-works. There was a vast accumulation of vertebræ, ribs and baleen there, and the younger members of the party took advantage of the opportunity to make private collections, which Captain

Tanner very kindly allowed us to bring back on the ship. The odor thus transferred to the hold of the *Fish Hawk*, while in itself not small, we could assure the captain would not be missed on the point, where it was massive, corporeal and all-pervading.

Almost daily collections were made of surface material. Trips for this purpose were made in the Fish Commission launch, *Cygnat*, D. H. Cleveland, captain, and W. H. Lynch, engineer. Now and then when trips were in the daytime we contrived to have a race with the Forbes launch, *Coryell*, at which times, if the energy with which Lynch shoveled coal could have been transferred directly to the machinery that actuated our propeller, we should have easily won. As it was, unless my memory is at fault, the *Coryell* usually got the better of us.

Two or three times a week collections were made in the evening, beginning just after dark. A favorite place for making these evening collections was in the "hole," where the launch would be made fast to the nun buoy, and for an hour or more towing-nets were used. The material thus collected was then taken back to the laboratory, where it was immediately examined. In this way much information was obtained of the nature, times, seasons, stages of development and habits of the life at and near the surface. I do not remember hearing in those years the word plankton used. Possibly a more tolerant interest might be awakened in a modern audience in these old-time investigations if this paragraph had been headed with the cabalistic legend: Plankton studies.

In 1882 dredging on the outer continental slope was still being vigorously carried on, most of it in depths ranging from 100 to 400 fathoms. Trips to this locality were usually called Gulf Stream trips. The

great abundance of living things brought up by the trawl from this under-sea edge of the continent was still yielding many new and interesting forms, and, since it was important that the material be cared for promptly, three or four of the younger men were always detailed for this work. Professor Verrill himself did not go on these trips, the motion of the ship quickly incapacitating him for work. Indeed, any one who can endure the motion of the *Fish Hawk* for 24 hours without experiencing unpleasant sensations can qualify as an able seaman, at least as far as immunity from sea-sickness goes. Our trips to the Gulf Stream were carried out in this wise: The precise time of departure was not set until a short time before starting. This was because the *Fish Hawk*, having been designed as a kind of wandering fish hatchery whose field of operation was to be limited largely to such bodies of water as Chesapeake Bay, was not then and is not now regarded as a vessel that could safely weather a severe storm. It was Professor Baird's custom, therefore, before sending the *Fish Hawk* on an outside trip, to get a special bulletin from the weather bureau saying that no atmospheric disturbances were indicated for the North Atlantic coast for the next forty-eight hours. Favorable conditions prevailing, we were then notified, sometimes but an hour or two, or even less, before starting, that we were expected to make a trip to the Gulf Stream. The usual time for starting was 5 p.m. We steamed out all night, and upon the following morning, having now arrived at the outer slope, began dredging. As a rule the trawl was overboard by 5 o'clock; the first haul was consequently made before breakfast. My recollection of these days are of hours of not altogether unalloyed pleasure. To this day the smell of material brought fresh from the bottom of the sea awakes memories that

I would fain let slumber. The material which but a short time before had been on the bottom at a temperature but little above the freezing point was unpleasantly cold to handle. Then there was the ever-present discomfort caused by the rolling of the vessel, accentuated to a stomach-racking degree by the motion communicated to the vessel when the dredging was in operation. Under such conditions it should not be a matter of wonder if from time to time the most zealous of naturalists turned away from the large seive, into which the material from the trawl was emptied, with feelings akin to those experienced by the fishes just before they lost consciousness as they were being hurried from the bottom. These fishes came to the surface with either swim-bladder or stomach protruding from their mouths, and their eyes starting from their sockets. Such phenomena are due to the enormous release of pressure experienced in being in a few minutes transferred from the bottom to the surface, a difference approximating 50 pounds for each one hundred feet, or 300 pounds per square inch for a depth of one hundred fathoms.

The forms brought from the bottom on the borders of the Gulf Stream, were so varied and so different from those found along shore or at moderate depths that, until they had been seen repeatedly, they caused the disturbing motions of the *Fish Hawk* for the time to be forgotten. For example, an annelid which lives in a tube constructed from its own bodily secretions early attracted my attention. The tube had the appearance of quill; when burned it gave the same odor as burning quill, and, when cut into the shape of a pen, could be used for writing the worm's name. Another was an interesting case of symbiosis, or life-partnership, that had been made familiar to those of us who had listened to Professor Verrill's lectures. Here it was

seen in the living condition, a hermit crab having its home in a living house, that grew as the crab grew, and consisting of a colony of sea-anemones. Close examination would usually show that the sea-anemones had originally established themselves on the shell of a mollusk in which the hermit crab was living. The *cœnosarc* common to the anemone colony not only grew entirely over the shell, but continued the lip of the shell with enlarged gap so that the crab did not need to seek a new and larger shell in subsequent molts. Furthermore, the advantage of this partnership is mutual. On the one hand the crab is provided with a house which adjusts itself to its needs and, with its frieze of tentacles, armed with nettle-like defensive organs, gives him a measure of protection from his enemies. On the other hand, the anemone is carried about by its active partner and is thus afforded a much more varied experience than it would have if growing on a non-motile object. Moreover, the crab, being a greedy feeder, very unlike Chaucer's nun, who, we are told, "let no morsels from her lippen fall," allows many fragments of his meals to float off in the surrounding water, is thus, while eating, doubtless often encompassed by a cloud of crumbs which are as manna to the colony of polyps which thus become literally commensals or true table companions. Such matters are, of course, familiar to students and teachers of zoology, but may not be so familiar to those whose biological training has proceeded along different lines. An interesting feature about this case of commensalism is that, while several hundred specimens were collected in the expeditions of the *Fish Hawk* to the Gulf Stream, these two species were always found associated as commensals. In other words, this particular species of hermit crab was not found except as a commensal of this particular species of sea-

anemone, and this particular sea-anemone was not seen except as a commensal of this particular species of hermit crab. Other cases of commensalism between sea-anemones and crabs were encountered, but none in which the commensals were so faithful to each other as in this.

The material of a haul having been cared for, some of it assorted, labeled and placed in proper preserving fluid, some of it kept in sea-water to be brought alive to the laboratory, we quickly relapsed into that condition of indifference to all things, past, present and to come, which characterizes alike the sea-sick and the aspirants to Nirvana. From this apathetic state we aroused less and less completely as the day wore on. On one or two trying occasions when a heavy swell rocked the *Fish Hawk* in its glassy cradle, much of the material in the last haul, in spite of its great value from the point of view of those who desired an accurate knowledge of the life on the ocean floor, was huddled together and brought back to the laboratory in much the same condition in which it was scraped from the bottom by the trawl.

Before the trawl was put overboard a sounding was made. This was done by means of an ingenious machine invented by Captain Sigsbee of the navy. Instead of the hempen cord of the older machines fine piano wire was employed. A thermometer was also sent down with the sounding lead, the case in which it was enclosed being fastened securely at the lower end, while the upper end was held to the wire by a detachable clamp which was loosed by a lead traveler sent down the wire. This tripped the thermometer, which, in turning over, broke the column of mercury in a bend of the tube, so that the mercury in the filiform portion of the tube remained and could be read in the reversed instrument when it reached the surface. Specimens of the bot-

tom were also obtained. Thus each sounding yielded data of depth, temperature and character of the bottom. Now and then temperatures at different depths in the same locality were taken. The bottom was largely a soft foraminiferal ooze into which the trawl sank, the net sometimes bringing up a large mass of mud, in spite of its having traversed a hundred fathoms or more of clean sea-water on its way to the surface. Occasionally a boulder of fair size was captured, and on more than one occasion the load was too heavy for the net. What came to the surface then was a broken net with, at most, a few small starfishes and serpent-stars clinging to its sides. At such times the comments of Captain Tanner resembled some of the more lurid passages in the novels of Captain Maryatt.

Most of the dredging work of the *Fish Hawk* on the Gulf Stream was done with a beam trawl. The lower end of the net was kept on the bottom by means of leaden weights, while the net itself was buoyed up with hollow balls of thick glass. Sometimes these balls, which were empty when they were started down, came to the surface with water inside. This appears to be due to the extreme pressure which forced water through minute openings in the glass.

In addition to the bottom work some attention was given to the collecting of surface material by means of towing nets and dip nets. Specimens of the Portuguese man-of-war and other Siphonophora were frequently taken as well as *Hippocampus* and various other forms found in the floating gulf-weed. Sharks also were sometimes taken, and, on one trip I remember, three or four porpoises were harpooned. This latter, however, was rather by way of diversion and did not enter into the more serious work of the trips.

About sundown the dredging was discontinued; the ship's course was laid for

Gay Head light, and the thump, thump of the engines began, to keep up all night. On the following morning, soon after sunrise, we would sight Nomansland or Gay Head, and about 9 o'clock were tied up at the wharf in Great Harbor, which, as I remember, was just west of the Luscomb wharf.

Sometimes the fair-weather forecast did not hold good for the whole trip. That meant an uneasy time for Captain Tanner, who, it was said by other officers and by the crew, never slept from the time the *Fish Hawk* put out to sea until she was safe in harbor. Of one of these return trips I have a vivid recollection. With little provocation the *Fish Hawk*, not then provided with a bilge keel, could get up a 45° roll. On this occasion soon after we turned in we had an exhibition of rolling and pitching and various combinations of these severally trying motions that far outdid any former exhibitions of similar nature. Now and then the twin screws, prophetic of the air craft of the present day, were whirling in air, while on board there was a constant rattling and banging, creaking and slamming, with an occasional crash of breaking glass that kept us awake but, so far as I remember, did not cause us any alarm. We did not know much about the sea-going qualifications of the *Fish Hawk*, while we had an extravagant confidence in the ability and caution of the captain.

When we reached port on this trip Captain Tanner put in circulation a new story. In order to understand the point of the story it is necessary first to explain that, just as now the title of a scientific worker in Woods Hole is doctor—so much so indeed that one readily understands why a little girl a few years ago brought word upstairs to her mother that Dr. Boles, the carpenter, was below—so, in the 80's, the title of professor was similarly employed.

"The Professor" always, and to all persons, meant Professor Baird. Otherwise the title of professor was bestowed with great liberality and impartiality. Indeed we young assistants were called professors by the crew of the *Fish Hawk* as cheerfully and naturally as the same persons would have given the title to an instructor in the art of self-defense. It so happened on this trip that there were some worthies on board who occupied the spare staterooms, and mattresses were spread in the ward room for the assistants. Captain Tanner said that when it came on to blow he sent his servant, George, below to see if everything had been made secure. When he returned the captain asked: "Well, George, is everything clewed up tight?" "Yas, sah." "You're sure that all's been made snug?" "Yas, sah." "Nothing loose?" "No, sah, 'scusin of a few professors adrift on de ward-room flo'."

On a number of the trips made to the Gulf Stream in 1882 trawl lines and bait were taken along for the purpose of fishing for the tile-fish, whose destruction in enormous numbers had been reported by incoming vessels in the spring of that year. These vessels reported that they had seen countless millions of fish in a dead or dying condition covering thousands of square miles of the sea. The tile-fish (*Lopholatilus chamaeleonticeps*) was first taken in 1879. It is a bottom fish with habits much like the cod, and it occurred in vast numbers in the waters bordering the Gulf Stream between Hatteras and Nantucket previous to the season of 1882.²

Professor Baird had hoped that profitable fisheries for this species might be opened up, and was very anxious to have specimens secured to prove that the species was still extant. I remember a remark that Captain Chester made as he came alongside

² U. S. Fish Com. Report for 1882, pp. 237-64.

the ship on our first trip to the tile-fish grounds, after underrunning the line that had been set for several hours. There were a considerable number of fish of various kinds in the bottom of his boat which he had taken from the line. Some one sung out from the ship asking him if he had taken any tile-fish. His reply was: "Not a lophilatilus, not a chameleonticeps!" In fact no tile-fish were taken until July, 1899. They were taken again in July, 1900. The hoped-for fisheries for the tile-fish have not yet been realized.

The *Albatross* started on her first trip from Woods Hole July 16, 1883. The trip lasted, as I remembered it, five days. It was my good fortune to be one of the number assigned to this trip. In attempting to review the events of this trip I find that my ability to recall details is limited to a not large number of incidents which rise in my memory like pictures. Life on ship board is somewhat monotonous at best, and when one experienced an undertone of discomfort, there follows the natural tendency to dismiss all recollection of it from the mind.

One experience, however, was so unique, and, fortunately, not associated with feelings of discomfort, that I have often lived it over in my memory. That was when the first haul was made from the deep sea. A depth, as I remember it, of 1,400 fathoms, or nearly 1.6 miles, was shown by the sounding that was made just before the trawl was put overboard. As the dredging operations of the *Fish Hawk* had been limited to localities where the maximum depth was less than half this depth, this was the first experience of any one on board with really deep-sea dredging. Of this event the picture which I carry in my memory is a moving one of perhaps a little more than a quarter of an hour's duration, beginning a few minutes before the trawl appeared

and ending after we had spent a few minutes in overhauling the material. The trawl had been over several hours. I have not verified my impressions, but I think it was possibly as much as six hours. When the indicator showed that the trawl was within a few fathoms of the surface every one began to peer down into the transparent water to catch sight of the messenger that had been on such a strange voyage of discovery. It was long past sunset and quite dark, but the scene was brilliantly lighted by electricity. A strong arc-light suspended over the water made sufficient illumination to reveal a school of flying squid pumping themselves about in the water. The light penetrated to sufficient depth to enable one to trace the wire cable far down until it was lost in the darkness below. For some reason, I do not know why, I glanced around. What I saw and remember would, I think, make a worthy theme for a great painting. In the foreground were the naval officers in their trim uniforms; near them the little band of investigators in their nondescript but not unpicturesque attire. Grouped on the fore-castle was almost the entire ship's crew, the white trappings of the sailors standing out bravely under the rays of the powerful electric light. Above, below and around about, darkness. The picture was given the needed motif by the approaching trawl upon which all eyes, but my own for a brief interval, were centered. I find myself still as a somewhat detached spectator recalling this scene, and think of this little hemisphere of light in the general gloom that shrouded the great expanse as symbolic of the light of science in the world, which is shining not only to reveal the things that may be seen, but striving to illumine the depths and thus bring to the surface a knowledge of things that lie deeply hidden. This scene lasted but a short time. Pres-

ently we could discern, far down in the transparent waters, a formless thing that quickly took shape, and then the trawl was hauled above the surface, the boom swung in, the net emptied into the great sieve, and we had our first view of living examples of the abyssal fauna. Those forms that lay in the sieve had, only an hour or two before, been resting on the ocean floor where their ancestors had lain undisturbed through the ages of the past with no traditions to affright them by visions of some mysterious being reaching down to snatch the dwellers of the abyss to the unknown regions above.

We had become familiar with the rich and varied fauna of the continental slope, and some of the party had had much experience in dredging in depths of as much as 500 fathoms, but among this material, not large in the mass, were forms that at first no one could assign even to a probable phylum. For example there were a half dozen or more curious-looking objects, not unlike in shape and size to an ordinary five-cent loaf of bread, perhaps a little flatter, and in color and consistency resembling the compound ascidian known as sea-pork. When these objects were brought to the attention of the mollusk specialist he would have nothing to do with them, saying that they were ascidians, or, possibly, worms. The annelid specialist passed them by. It was really not until some of these puzzling creatures had been lying for some time in a tub of sea-water that they were seen to be holothurians, sea-cucumbers of unusual appearance plucked from the abyss. Details of this deep-sea fauna may be obtained from the published reports of the Fish Commission. A strange world was opened up to the imagination by these creatures from the depths: Fish with eyes living in those regions whither the light of day can not penetrate! Whence comes the light which

the presence of organs of sight implies! Gorgonia corals, slender and fragile and as delicate as the finest grasses of autumn, shining in shadow with a brilliant phosphorescent light, suggest that if we could see this ocean floor, we would see it dimly illuminated by the phosphorescence of its living denizens, among them groves of gorgonians, motionless in the currentless water and shining with a light literally not seen on sea or land.

I propose now to record brief memory sketches of some of those who were associated with the Fish Commission at the Woods Hole laboratory in 1882 and the years immediately succeeding.

SPENCER FULLERTON BAIRD

Information regarding the life and works of this great American can be had from the published accounts. My purpose here is simply to record a few personal recollections.

I first met Professor Baird in the summer of 1882 when I came to Woods Hole as an assistant of Professor Verrill. About the first thing he said to me was to ask what particular field of zoology I was interested in. By this question I can see now two striking characteristics of Professor Baird's mind: First, his interest in young men who were inclined to the study of nature, and, second, his conviction that such study was best begun by becoming familiar with some particular group of animals. He was then about 60 years of age but looked older than his years. He was a large man, probably fully six feet in height, and possessed of a powerful frame. He stooped slightly, his movements were rather slow and his manner deliberate. His hair and beard were becoming gray. He had a kindly smile, a genial but quiet manner, and a bearing which might not improperly be called patriarchal. He had a wholesome sense of humor,

and was not unacquainted with some of the lighter literature of the day. He read with zest, as many of us did, Rider Haggard's "King Solomon's Mines," and was so much interested in Mrs. Burnett's "Little Lord Fauntleroy," which came out in serial form in *St. Nicholas*, to which he was a subscriber, that he asked the author's husband whether the story had been completed, or whether Mrs. Burnett was supplying copy to the magazine month by month. He was much relieved when told that the manuscript for the entire story had been given to the publishers, since he could now go on with the reading without fearing that some calamity might happen to the author that would prevent her finishing the story. He gave the impression of being one who had succeeded in establishing entire control over himself. I never saw him roused out of his habitual serenity but once. That was when a collecting expedition for a special purpose was being delayed in its starting because the commander of the *Lookout* wanted to finish a game of tennis he was playing on the grounds near the Dexter House. (The *Lookout* was a steam-yacht used by Major Ferguson, the assistant commissioner.) When it was reported to Professor Baird that the expedition was being delayed he left his office and walked at a very rapid pace down toward the laboratory on Little Harbor. The commander of the *Lookout*, sighting Professor Baird bearing down upon him under full steam, abruptly suspended his game and a few minutes later the *Lookout* was under way.

Professor Baird's knowledge of living things, especially of fishes and birds, was extensive, exact and detailed. He belonged to the older school of naturalists whose view of nature was bounded by no narrow horizon. Unfortunately for him and for science his later years were encumbered by administrative details which, although he attended to them apparently without

worry, were often perplexing, always time-consuming, and grew in volume with the years. As secretary of the Smithsonian Institution and as commissioner of fish and fisheries his administrative burdens were very great. His nature was such that he could not easily shift burdens to other shoulders. As a consequence of all this he suffered the penalties that follow long hours at his desk substituted for a life that had been formerly in good part spent in the open.

In the interval between the summers of 1886 and 1887 his health failed, and in August, 1887, he died in the residence building into which he and his immediate family and the greater family making up the commission force had moved but three years before.

The funeral services were read by the rector of the Episcopal Church of Woods Hole. To the prescribed church service were added two of the beatitudes which appeared to those who had been associated with him most intimately to reflect the high points of his character. They were the ones which pronounce blessings on the peace-makers, and on those who are pure in heart.

Professors A. E. Verrill and Sydney I. Smith are best known to Woods Hole workers for their voluminous and invaluable report on the "Invertebrate Animals of Vineyard Sound and Adjacent Waters." They were alike in that they were zoologists of unflagging zeal. In all other particulars they were unlike and good-naturedly antipathetic. The one was unemotional, dogged, and, to those who did not know him well, seemingly, at times, crusty. The other was quick, vivacious, open and frank in his manner at all times and to all persons. They invariably took opposite sides of any question that came up for discussion, whether it was scientific, political,

theological or philosophical. The only adverse criticism that I ever heard passed upon their use of time was that they often wasted it in argument over questions which, however they might be settled, if they ever were settled, would not advance human knowledge appreciably, or improve human practise materially. It must be remembered, however, that they were both prodigious workers and that their argumentation was about their only recreation. They did not smoke, and, indeed, were abstemious in all their habits, except in the matter of debate.

Professor Verrill's memory for details was almost uncanny. It was generally believed among us younger men that he could tell correctly at any time the exact number of spines on any parapodium on any species of annelid that he had studied, and he had studied those of the New England coast so effectually that no one has attempted to do much in a systematic way since his time. It was a matter of surprise to those who came to know him well to discover in him a kindly heart and a genial nature. It is a pleasure to record that he is still vigorous and complaining, as usual, because there are not more than twenty-four hours in the day. Professor Sydney Smith, too, is still much alive, and in spite of the great affliction in the loss of his sight, is still unquenchably bright and cheerful.

A peculiarity which Professor Verrill possessed as an arguer may be commended to any who may have to play the part of disputant. No matter what the nature of the interruption might be, or how often the interruptions were made, he never allowed them to divert him from the main course of his argument. I have often heard Mr. Sanderson Smith engaged in a furious debate with Professor Verrill, generally during the progress of dinner, where the fury, however, was all on the one side, and mani-

festing itself in frequent and energetic interruptions and expostulations, during which Professor Verrill would patiently pause, and, after the breath of his opponent was exhausted, take up his argument where it had been interrupted, and, with even voice, continue as if nothing had been said on the other side. By and by, at the proper place he might reply to the interjected arguments.

Richard Rathbun was working in the laboratory in those days. His special interest then was in parasitic copepods. He was a most industrious worker and smoked an amazing number of cigarettes while at work. His tireless industry in those days was prophetic of his subsequent, indefatigable, vacationless, administrative labors to which the splendid achievements of the National Museum are in no inconsiderable degree due.

George Brown Goode was one of the most well-balanced minds it has been my privilege to know. I remember very well his wonderfully clear and honest eye, his great expanse of forehead, his ready and intelligent interest in what we younger men were working at, his wise and stimulating suggestions. It is much to be regretted that he had not been chosen by one of the great universities, where, in surroundings less permeated with administrative detail, he might have developed the talents which I am sure would have made of him a great teacher, with a longer span of life than was his portion.

John A. Ryder, the most gifted, the most original, the most profound, the most unconventionally human of them all, withal a most likable man, stands out prominently among the workers at the Fish Commission laboratory in the 80's. Often have I sat in wonderment as I listened to his conversa-

tions, which were, indeed, largely monologues, and recall also a remark of Rathbun's, made a few years later. He said that Ryder would awaken lively interest at the meetings of the Biological Society in Washington, and hold their undivided attention throughout the entire meeting, although, often, he confessed, no one was exactly certain what he was actually talking about. He was wonderfully suggestive and always interesting. After having been a member of the faculty of the University of Pennsylvania for but a few years, he died at a comparatively early age. His death, as was that of the talented and beloved Montgomery, who some years later succeeded him to the same chair, was a calamity to the science of biology in this country.

Theodore N. Gill appeared to me to be a rather elderly man in 1882, but he could not have been much above fifty years of age. He was then and, unless his memory has yielded to the weight of years within the past few months, still is an animate ichthyology in himself. How a memory such as his could develop in these days of printed books, with their tabulated lists and bibliographies alphabetically arranged for ready reference, is a marvel. Names of varieties, species, genera, families, orders, synonyms, authorities, morphological details, literature in many tongues, seemed to be always at hand and ready for immediate use. In the variety, extent and accuracy of his knowledge he stands in a class by himself among the men I have known.³

Dr. Jerome Kidder, naval surgeon, was another of the interesting and capable men that Professor Baird attracted to himself and the commission. He had charge of such investigations as required a knowledge of chemistry. His personality is still a very real presence in my memory where he

stands as a model of good-breeding, good-humor and good-fellowship. He was possessed of intellectual endowments of signal brilliancy. His early death was mourned by a much wider circle than that bound to him by the ties of kindred.

Tarleton H. Bean was not engaged in field work much of the time in the years of which I am speaking, although he had been much in the field in the earlier days of the commission. As I remember him he was always animated and cheery, abounding in interesting and amusing anecdote, with an extensive and accurate knowledge of fishes and their ways.

Captain Z. L. Tanner, in 1882, was in command of the *Fish Hawk* whose construction he had superintended. Before that time he had been in command of the *Speedwell*. When in 1883 the *Albatross* was placed in commission he became her commander. While a naval officer with the rank of captain, he was not a graduate of the Naval Academy, but had been promoted for distinguished services in the Civil War. He had a florid complexion, a somewhat harsh voice, and a bluff and hearty manner, such as one naturally associates with the typical ship's captain. He was a strict disciplinarian, but just and impartial, and highly respected by all who served under him, or were in any way associated with him.

Captain J. W. Collins was the designer of the U. S. Fish Commission schooner *Grampus* and her first skipper. The *Grampus* was intended to be a model fishing schooner, and is distinguished as the prototype of the *We're Here* of Kipling's "Captains Courageous." He is remembered by me for his cordial and approachable manner, his profound knowledge of the fishing industry, especially on the Banks,

³ Professor Gill died September 25, 1914, aged seventy-seven.

and for his narratives of his own personal experiences and of those of others. One incident, the truth of which I have no reason to doubt, was that of two of his acquaintances, who loaded two dories from the flesh of a giant squid, which they found floating at the surface, leaving an amount which they estimated would have made another dory load. Other incidents of his narrating were not meant to be taken literally, as, when speaking of his experiences in Copenhagen, when attending an international fisheries meeting, where he said that it rained so much that horses frightened at a person who was not carrying an umbrella. Then there was his story of the commander of a vessel, who, sailing into his home port on the Norway coast when there happened to be no fog, did not recognize the place, and accordingly put out to sea, when, the usual fog setting in, he succeeded in a few hours in making his own familiar harbor.

Captain H. C. Chester had charge of the collecting apparatus and superintended the dredging operations. The trawls and nets were stored in what is now called the Stone Building, then known as the Old Candle Factory. Captain Chester was an ingenious and true son of the Nutmeg state. His inventive genius was highly valued by Professor Baird, as an examination of the Reports will show. He abounded in quaint and original humor. He had had much experience as a sea-faring man. It was well known among us that Captain Chester had taken a prominent part in the *Polaris* expedition, and that it had been due to his unflagging good-spirits in the presence of intense cold and extreme privation that the party that returned by land was brought through safely. We often tried to get him to tell us about that expedition but never succeeded. He preferred to talk about Noank, Connecticut, which he invariably spoke of as "the garden spot of the earth,"

and a famous variety of apple, which his father developed to grow in an orchard on a steep hill side. These apples, he averred, were flat on one side, which kept them from rolling down hill into his neighbor's field below.

Sanderson Smith I remember as an elderly man, probably Professor Baird's senior. I think that he had been an engineer by profession, but with a strong bent towards natural history. His work for the commission, besides looking after the mollusca, consisted in tabulating results of soundings, dredgings, temperature data, and the like. He was a model of good nature, more ready to do favors for others than to minister to his own comfort. In those days there were many visitors to the laboratory and Sanderson was always ready to drop his work, which the rest of us sometimes did reluctantly, to show visitors over the laboratory. James H. Emerton, Professor Verrill's artist, was very patient under these visitations to his table, but one day, I remember, he complained vigorously because some of the visitors had breathed down the back of his neck as they were watching him make a sketch.

Soon after we moved into the new residence building some of us one morning found Sanderson looking with a much puzzled expression at the new clock, across the face of which was printed a direction for winding, but which he was interpreting as a weather forecast. Pointing to it with an air of indignant agitation he said: "Why, why, why, what, what, what does that mean? 'Wind every Monday morning'!"

Leslie A. Lee was a most cheery and well-beloved member of Professor Baird's larger family in the 80's. He was an enthusiastic collector, capable of the best work, but whose love of collecting and of first-hand

observation overrode his inclination to put his knowledge into printed form. His publications bear no proper relation to his work and knowledge.

H. L. Bruner, one of the assistants in my time, grave and serious as a young man, was assiduous and painstaking in his work, and immune to sea-sickness. J. Henry Blake, who succeeded Emerton as artist, and was in the laboratory for three or four years, is another who has built himself a pleasant habitation in my memory.

Among the young men who worked in the laboratory on Little Harbor in 1882 and 1883 were also B. F. Koons, W. E. Saford, Peter Parker and Ralph S. Tarr. Tarr was so much impressed with the accuracy of Vinal N. Edwards as a weather forecaster that he declared that if Vinal Edwards said it was not going to rain in the afternoon he would still believe him even if his own senses told him that there was a genuine downpour.

A year or two later, Professor W. Libbey for at least a summer, and Professor W. B. Scott, as an occasional visitor, brought new ideas and methods, and Dr. McCloskie, too, brought a breeze of enthusiasm with him that was most refreshing.

Among the numerous visitors to the laboratory who tarried long enough to impress their strong personality on us younger men I recall most vividly and pleasantly Professor Cope and Doctors Osler and S. Weir Mitchell.

It is not my purpose to extend these reminiscences much beyond the days when Professor Baird's presence was the most potent influence in this community. I shall, however, insert a few observations on the season of 1889.

Returning after a year's interval, I found a complete change in the personnel, and but little change in the spirit which pervaded the laboratory. The laboratory was under

the efficient directorship of Dr. H. V. Wilson. The laboratory workers still had their mess in the residence building, where I greatly missed the benign presence of Professor Baird.

There was here, however, that summer, a man of quiet and unobtrusive manner, who, as it seems to me, had elements of real greatness in his nature in higher degree than any one whom it has been my fortune to know. That was Professor W. K. Brooks.

It was an interesting lot of young men that I found in the laboratory of the U. S. Fish Commission in 1889. There was E. A. Andrews, then and still of Johns Hopkins University; H. V. Wilson; F. H. Herrick; E. R. Boyer, C. B. Davenport, and W. M. Woodworth, post-graduate students of Harvard; M. C. Greenman, a post-graduate student of the University of Pennsylvania; R. P. Bigelow, C. F. Hodge, T. H. Morgan, and Sho Watase, post-graduates of Johns Hopkins. Of this group, Hodge, who has recently molted the effete east, has written of dynamic biology. I think it can be said with truth that he and the others of this little group, after the quarter of a century that intervenes, are to be reckoned as among the potent dynamic agencies in the biological science of this generation.

The Marine Biological Laboratory had been opened the previous summer. Dr. Whitman had already inaugurated the custom of having evening lectures. They were held in the one laboratory building in the room, I think, in which the invertebrate course is now conducted.

In 1889 cross-breezes were ruffling the calm of the biological atmosphere. There were some in the laboratory who stoutly denied that the surroundings did or could have any manner of influence on the germ cells. There was no god in animated nature but heredity and Weismann was his prophet. In those days also the neo-La-

marckians were in the land; sturdy Americans they were, who hardened their hearts at ideas made in Germany. One evening, I remember, we went over to the Marine Biological Laboratory to hear a lecture by Professor E. D. Cope. The lecture was on some mechanical factors in evolution. Professor Cope, the most scintillatingly brilliant American man of science that has yet appeared, told us about the shapes of the carpal bones in a number of extinct artiodactyles which he had been studying. He illustrated his lecture with numerous crayon sketches which he made while he was talking. His conclusion was that these bones owed their shape to the mechanical effects of pressure and stress, and were thus evidence of the inheritance of characters that had become impressed on lines of descent by the surroundings, and hence might be said to prove the inheritance of acquired characters. I recall that one of the young men, upon our return to the Fish Commission laboratory, characterized Professor Cope's lecture as puerile, which I did not think then, nor do I think now, is exactly a word that is needed to describe anything which Professor Cope said or did in 1889.

It has been my fortune once and again to hear more or less patronizing criticism of the way time was spent in the work of collecting and classifying the animal and vegetable forms which inhabit the waters of the Woods Hole region. Doubtless the time could have been better spent, but this remark may be made with equal justice concerning any sort of human endeavor. It may not be amiss to say that whatever the character of the publications of these earlier workers, the conversations to which, as a young man, I listened between such men as Professors Baird, Gill, Verrill, Smith, Goode, Ryder and Cope, contained nothing about priority of names, and little upon taxonomy in general, while they did abound

in discussions of such matters as the habits and distribution of animals, adaptation, development, function, behavior and heredity.

Looking back on the laboratory activities of those days and comparing them with the present with its varied application of the sciences of chemistry and physics to the study of the phenomena of life, the work done here in the 80's may seem narrow. It should be remembered, however, that no science has sprung at once into maturity. The immediate problem before the Commission of Fish and Fisheries was that of acquiring all the knowledge obtainable of the fishes of our coast and of their food and environment. It is not conceivable that this knowledge could have been gained in any other way than by a study of the conditions at first hand. Doubtless our knowledge is to be vastly extended by those experimental methods whereby animals are subjected to conditions which do not exist in nature, but such investigations, however valuable they may be in refining and extending our knowledge of life, would have been as much out of place in the days of Baird and Agassiz as the automobile and the locomotive would have been in the forests of this country 200 years ago.

Those of us who breathed the serene atmosphere of the days of Professor Baird, and have continued work somewhat similar to that which we began some three decades ago, have inherited, I trust, some of his kindly spirit that should enable one to listen to criticism with equanimity and to endure patronage without agitation of mind. Thus one may dwell beside the road and be a friend to the passing biological pageant. So he could be a respectful onlooker when, in 1898, he beheld the passing show, brave with many colors; when newborn ideas in biology must first be baptized in corrosive sublimate and then decked in

the royal purple of hematoxylin before they could be exposed to the awed gaze of the beholder. Likewise, in 1899, when the name of vom Rath was a word to conjure by; continuing in 1900, when nerve endings were the end and aim of all that was worth while, he could only wonder and be silent. I remember in 1899 asking an acquaintance that I had made the previous year what he was working at. His reply was: "I have been working for the past two years on the nerve endings of *Arenicola*, but have not got any results yet." But with the introduction of experimental methods the epoch of zoological fads came to an end. Now our dweller beside the road listens with appreciation to illuminating lectures on a variety of subjects, where problems new and old are attacked from various and unusual points of approach and by a multiplicity of methods. He listens with delight to the lecturers who announce the results of their researches, but with a conviction that is sometimes in inverse proportion to his knowledge of the subject under discussion. Often he is inclined to accept these conclusions with enthusiasm, only to have his enthusiasm chilled when he hears what the lecturer's friends have to say about the lecture on the following morning.

When, in more recent years of the Fish Commission, or Bureau of Fisheries, as it is now called, Parker, with no other equipment than a pair of hat-pins, demonstrated the functions of the otoliths of fishes, and, with an apparatus which he constructed with the aid of a saw and hammer, supplemented by a simple surgical operation, discovered the function of the lateral line in fishes, and in equally simple fashion cleared away the fog that enveloped our knowledge of how much or how little fishes hear sounds either above or beneath the water; when Sumner showed by ingenious but easily worked experiments the degree to which

flat-fishes adapt themselves to their surroundings; when Field gave proof as convincing as that of the proverbial pudding that *Mytilus edulis* is truly an edible, and that the smooth dog-fish by some other name would be eagerly sought in the markets; when these pieces of original work and others like them, of which many could be named, are considered, we feel that they represent in good degree the kind of investigation which would have won Professor Baird's hearty sympathy and approval. I am inclined to think, however, that he would have viewed with still greater favor the Bulletin of the Bureau of Fisheries for 1911 reporting a Biological Survey of the Waters of Woods Hole and Vicinity.

EDWIN LINTON

WASHINGTON AND JEFFERSON COLLEGE,
WASHINGTON, PA.

THE INTERNATIONAL ENGINEERING CONGRESS

THERE will be held at San Francisco, from September 20 to 25, 1915, an International Engineering Congress, organized and conducted under the auspices of the American Society of Civil Engineers, the American Institute of Mining Engineers, the American Society of Mechanical Engineers, the American Institute of Electrical Engineers and the Society of Naval Architects and Marine Engineers. General G. W. Goethals has consented to act as honorary president and is expected to preside over its general sessions. The following eminent engineers have consented to serve the congress as honorary vice-presidents: Professor Richard Beck, Sir J. H. Biles, Otto T. Blathy, Commander Christian Blom, Professor André Blondel, Dr. C. E. L. Brown, Dr. Emil A. Budde, Henry Le Chatelier, Professor Hermann Hüllmann, Wm. Henry Hunter, Professor Luigi Luiggi, Rear Admiral Yoshihiko Mizutani, W. M. Morday, Sir Charles Parsons, Jean L. de Pulligny, V. E. Timonoff, R. P. J. Tutein-Melthenius, H. H. Vaughn, Sir Wm. Willcocks.

The papers to be presented before the congress will cover the general field of engineering and will be published in ten volumes.

The papers in general are intended to treat the various topics in a broad and comprehensive manner and with special reference to the important lines of progress during the past decade, the present most approved practices and the lines of present and future development.

The general fee for membership in the congress is \$5, which will entitle the member to receive the index volume and any single volume of the transactions he may select, together with the right of participation in all the general activities and privileges of the congress. The committee of management must know at the earliest practicable date the number of members in the congress. Effective plans in regard to the publication of the transactions, as well as all arrangements looking toward the proper ordering of local affairs during the week of the congress, require this information.

It is expected that there will be arranged a number of excursions to points of engineering and general interest within practicable reach of San Francisco, and every effort will be made to enable visiting engineers to inspect personally such engineering works as are especially typical of engineering on the Pacific Coast. Further information of general interest and importance regarding the congress will be given publicly through the technical press, and to all subscribers notice will be sent containing more complete information as to papers, sessions of the congress, excursions, travel routes and itineraries, hotel rates and accommodations, and other matters of importance.

Mr. W. F. Durand is chairman and Mr. W. A. Cattell is secretary of the committee of management, the address of which is Foxcroft Building, San Francisco.

EDITH JANE CLAYPOLE

THE following minute in memory of Dr. Edith J. Claypole, who died in March, as a result of infection incurred in the preparation of typhoid vaccine for the armies of Europe, has been adopted by the Science Club of

Wellesley College. It has also been embodied in the minutes of the Academic Council:

The Science Club of Wellesley College records its sense of loss in the death of Edith Jane Claypole, a charter member of the club, its first secretary, and active both in its foundation and in its early conduct. Descended from a father who was himself a distinguished man of science, and receiving her early education at home, she was by inheritance and training exceptionally fitted for the line of work to which she chose to devote her life. She early exhibited unusual capacity for research; in the field of cell-studies and pathology her many papers are evidence of her power of achievement. As a teacher she opened the eyes of her students to the beauty and significance of living things, revealed to them the method of science, and inspired them with the high nobility of its aims. Members of other departments recognized the open-mindedness and appreciation that marked her attitude toward all branches of scientific activity. As a physician she early became interested in preventive medicine, and to its advance she devoted herself without reserve. Through her researches in pathology, particularly in certain obscure cases of infection and in typhoid immunization, she won distinction, and in the application of these researches to the needs of humanity, she has now crowned her service with the gift of her life. Her charm of manner and winsomeness of spirit, with a strong and wholesome nature, quick and tender in its response to the needs of others, and her unflinching steadfastness in friendship, endeared her to large circles. We, the members of the Science Club, express our sadness in the loss of a comrade, and our appreciation of her service to science and to humanity.

SCIENTIFIC NOTES AND NEWS

THE Civic Forum Medal of Honor awarded annually for "distinguished public service" has been presented to Mr. Thomas A. Edison.

DR. ABRAHAM JACOBI was the guest of honor at a dinner in the Hotel Astor given by the physicians and officers of the Bronx Hospital on the occasion of his eighty-fifth birthday.

At the annual meeting of the American Academy of Arts and Sciences, held on May 12, at its house, 28 Newbury Street, the following officers were elected:

President, Henry P. Walcott; Vice-presidents, Elihu Thomson, William M. Davis, A. Lawrence

Lowell; *Corresponding Secretary*, Harry W. Tyler; *Recording Secretary*, William Watson; *Treasurer*, Harry H. Edes; *Librarian*, Arthur G. Webster; *Chairman of Rumford Committee*, Charles B. Cross; *Chairman of C. M. Warren Committee*, Henry P. Talbot; *Chairman of Publication Committee*, Edward V. Huntington; *Chairman of House Committee*, Hammond V. Hayes.

At the annual election of officers of the Boston Society of Natural History, the following were chosen: *President*, Edward S. Morse; *Vice-presidents*, Robert T. Jackson, Nathaniel T. Kidder, William A. Jeffries; *Secretary*, Glover M. Allen; *Treasurer*, Edward T. Bouvé; *Councillors for Three Years*, Charles F. Batchelder, Reginald A. Daly, Merritt L. Fernald, William L. W. Field, John C. Phillips, William M. Wheeler, Edward Wiggleworth, Mary A. Willcox.

THE Barnard gold medal awarded every fifth year by Columbia University, on the recommendation of the National Academy of Sciences, "to that person who, within the five years next preceding, has made such discovery in physical or astronomical science, or such novel application of science to purposes beneficial to the human race, as may be deemed by the National Academy of Sciences most worthy of the honor," will be given this year to William H. Bragg, D.Sc., F.R.S., Cavendish professor of physics in the University of Leeds, and to his son, W. L. Bragg, of the University of Cambridge, for their researches in molecular physics and in the particular field of radioactivity. The previous awards of the Barnard medal have been made as follows:

- 1895—Lord Rayleigh and Professor William Ramsay.
- 1900—Professor Wilhelm Conrad von Röntgen.
- 1905—Professor Henri Becquerel.
- 1910—Professor Ernest Rutherford.

THE Butler gold medal to be awarded every fifth year by Columbia University for the most distinguished contribution made during the preceding five-year period to philosophy or to educational theory, practice or administration will be given to the Hon. Bertrand Russell, F.R.S., lecturer and fellow of Trinity College, Cambridge, for his contributions to logical theory. The Butler silver

medal is to be awarded to Professor Ellwood Patterson Cubberley, of Leland Stanford Jr. University (A.M., Columbia, 1902; Ph.D., 1906), for his contributions to educational administration.

THE city of Philadelphia, acting on the recommendation of The Franklin Institute, has awarded the John Scott Legacy Medal and Premium to Herbert Alfred Humphrey, of London, England, and to Cav. Ing. Alberto Cerasoli, of Rome, Italy, for the Humphrey Pump, a device for raising water by the direct application of the explosive energy of a mixture of combustible gas and air. In the pump, the momentum of a moving column of water is utilized to draw in and compress in a suitable chamber a charge of the gas mixture whose explosion raises the water.

THE Edward Longstreth Medal of Merit of the Franklin Institute has been awarded to the late Mr. George A. Wheeler for his escalator. The basic invention was first disclosed in a patent granted to Mr. Wheeler in 1892, and a number of patents were subsequently issued to him for improvements and developments.

At the annual meeting of the Boston Society of Natural History, held on May 5, the two annual Walker Prizes in Natural History were awarded. The first, of sixty dollars, was given to Miss Emmeline Moore, of the department of biology, Vassar College, and the second, of forty dollars, to Miss Edith B. Shreve, of Tucson, Arizona. The two successful essays were entitled, respectively: "The Potamogetons in Relation to Pond Culture" and "An Investigation of the Causes of Autonomic Movements in a Succulent Plant." These annual prizes are awarded for the two best essays submitted on subjects selected by a committee of the society. For the years 1916 and 1917 the committee announces that competitive essays will be received on "any subject in the field of natural history" thus allowing wide scope.

THE Howard Taylor Ricketts Prize for research in the department of pathology and hygiene and bacteriology at the University of

Chicago has this year been awarded to Miss Maud Slye for her work on "The Influence of Inheritance on Spontaneous Cancer Formation in Mice." This prize is awarded annually on May 3, the anniversary of Dr. Rickett's death from typhus fever acquired while investigating that disease in Mexico City.

MR. C. E. LESHNER, associate geologist of the land-classification board of the United States Geological Survey, has been assigned by the director of the survey to take charge of the work of compiling the statistics of coal production published in the annual volume "Mineral Resources." This work has heretofore been directly under Edward W. Parker, whose resignation from the Geological Survey is effective July 1.

DR. EDWARD C. ROSENOW, of the Memorial Institute of Infectious Diseases, Chicago, has been appointed chief of bacteriologic research, Mayo Foundation, Rochester, Minn. Dr. Rosenow will begin his new work on July 1.

THE following have been appointed by the trustees of Columbia University as the board of managers of the George Crocker Special Fund for Cancer Research for three years from July 1 next: Dr. T. Matlack Cheesman, Dr. Walter Mendelson, President N. M. Butler, Dean Samuel W. Lambert, Professor Warfield T. Longcope, Professor William G. MacCallum and Professor Francis Carter Wood.

DR. J. ALEXANDER MURRAY has been appointed general superintendent of the Imperial Cancer Research Fund and director of the laboratories, in succession to Dr. E. F. Bashford.

DR. LENTZ, director of the Prussian imperial health office, has been appointed the reporting councilor in the medical department of the ministry of the interior, as successor of Dr. Abel, who has been transferred to the Institute of Hygiene at Jena.

MR. LEO E. MILLER writes to the American Museum of Natural History from South America that he has completed his work in Antioquia and on March 30 sailed from Baranquilla to Colon *en route* to Bolivia, where it is proposed to inaugurate a zoological sur-

vey similar to that which the museum has conducted in Colombia for the past five years. Mr. Miller's collections, amounting to two thousand birds and mammals, has been received by the museum.

DR. ROBERT F. GRIGGS, of the department of botany at the Ohio State University, has been selected by the National Geographic Society to lead an expedition to study the vegetation of the Katmai district in Alaska. The purpose of the expedition is to study the means by which vegetation gains a foothold on the volcanic ash with which the country was covered by the eruption of Katmai in 1912. This ash-covered region is many hundreds of miles in extent, covering a portion of the Alaska Peninsula and the greater part of Kadiak Island.

AN excursion to the Hawaiian Islands, under the charge of Professor George H. Barton, director of the Teachers' School of Science, will leave Boston on July 4.

MR. LLOYD B. SMITH, of the Associated Geological Engineers, has returned to Pittsburgh, after spending three months in the oil fields of Mexico and Central America.

ALVIN J. COX, Ph.D. (Breslau), instructor in chemistry at Stanford University from 1904 to 1906, has returned to San Francisco on a leave of absence to take charge of certain features of the Philippine exhibits at the exposition. He has held the position of director of the United States bureau of science in the Philippine Islands.

PROFESSOR W. H. KAVANAUGH, head of the experimental engineering department, University of Minnesota, has been appointed a member of the international jury of award, department of machinery, at the Panama Exposition, San Francisco. Professor Kavanaugh is spending the month of May at the exposition, judging exhibits.

PROFESSOR H. H. STOEK, head of the department of mining engineering of the University of Illinois, has been granted a leave of absence to act as a member of the Committee on Awards for Mining Exhibits at the San Francisco Exhibition. Professor Stoek is now in California.

PROFESSOR ROBERT A. MILLIKAN, of the University of Chicago, delivered the "Thomas Lectures" at Richmond College in April. The general topic was "The New Physics." In his first lecture Dr. Millikan recounted some of the important recent discoveries in the field of radioactivity and X-rays and discussed the significance of these facts to modern science and life. The second lecture was given to a description of some of the properties of the electron, and the methods by which these properties had been discovered.

DIRECTOR JOHN F. HAYFORD, of the College of Engineering of Northwestern University, addressed the engineering sub-division of the Chicago Association of Commerce on Friday evening, May 14, on the subject "Chicago as an Engineering Center."

PROFESSOR LOUIS KAHLENBERG, of the University of Wisconsin, delivered the annual address before Phi Lambda Upsilon, the honorary chemical society of the University of Michigan, at Ann Arbor, on May 13. The subject was "A Neglected Principle of Chemistry and some of its Applications."

UNIVERSITY AND EDUCATIONAL NEWS

THE trust estate of \$3,250,000 left by Miss Elizabeth Thompson, will on the death of her brother and sister be equally divided among the following institutions: The Children's Aid Society, the New York Association for the Improvement of the Condition of the Poor, the New York Historical Society, the Society of the New York Hospital, the Presbyterian Hospital and Columbia University.

THE Michigan legislature has appropriated \$350,000 for the erection of a new university library building for the University of Michigan.

THE James Buchanan Brady Urological Institute of the Johns Hopkins Hospital, made possible through Mr. Brady's gift of \$600,000, was formally opened on May 4. Among those who made speeches were Dr. Hugh H. Young, head of the institute, and Dr. William H. Welch.

DR. THOMAS ORDWAY, of the Harvard Medical School, has accepted the deanship of the

Albany Medical College. Dr. Ordway was formerly professor of pathology in the medical school of which he now becomes dean.

G. V. COPSON, now specializing in dairy bacteriology in the University of Berne, Switzerland, has been appointed instructor in pathological and dairy bacteriology at the Oregon Agricultural College.

DR. E. F. MALONE, of the department of anatomy, University of Cincinnati, has been promoted to be associate professor of anatomy.

DR. ERNEST LINWOOD WALKER, formerly chief of the biological laboratory of the Federal Bureau of Science, and chief of the department of medical zoology at the University of the Philippines, Manila, has been appointed associate professor of tropical medicine at the George Williams Hooper Foundation for Medical Research, University of California.

PROFESSOR R. C. LODGE, who has been this year at the University of Minnesota, has been appointed professor of philosophy and psychology at the University of Alberta.

DISCUSSION AND CORRESPONDENCE

BALANCED SOLUTIONS AND NUTRITIVE SOLUTIONS

MR. TRUE's article on "Antagonism and Balanced Solutions"¹ closes with the following remarks.

In both sea water and the more or less dilute nutrient solutions present in the soil, normal life is sustained, as a rule, only in mixtures of proper proportions and necessary concentration. Since salts are required in both cases to overcome the harmful action of pure water, as well as that of the salts themselves, there seems to be no reason to seek to limit the use of the term "balanced solutions" in the manner suggested by Loeb and Osterhout. Unless we admit that malnutrition due to a deficiency in nutrient salts is a form of toxicity excited by the substances present, we can hardly escape the alternative proposition that the missing salts are injurious in *absentia*.

Since the writer is responsible for the introduction of the term physiologically balanced salt solutions,² he may be pardoned for pointing out that in his opinion neither of the

¹ SCIENCE, N. S., XLI, No. 1061, p. 653, 1915.

² Loeb, *Am. Jour. Physiol.*, III., p. 445, 1900.

two alternatives in the last sentence of Dr. True is correct. The writer defined physiologically balanced salt solutions as solutions in which the toxic effects are annihilated, which each or certain constituents would have if they were alone in solution. Thus the fertilized egg of *Fundulus* develops naturally in sea water, is killed in a pure NaCl solution of the concentration in which this salt occurs in sea water, and is kept alive if some CaCl₂ or KCl + CaCl₂ is added. Since the egg lives and develops perfectly normally in distilled water the CaCl₂ or KCl + CaCl₂ are only needed to counteract the directly injurious effects which the NaCl solution produces as soon as its concentration exceeds a certain limit (about $m/8$) (but not to counteract the injurious effects of distilled water which do not exist in this case). The nature of this injurious action of the NaCl solution of a sufficiently high concentration is perfectly well known, since it consists in the injury or destruction of the specific impermeability or semipermeability of the membrane.²

The term *physiologically balanced* or *protective* salt solution was intended to be used in contradistinction to the term *nutritive* solution. If from a nutritive solution one or the other constituent is omitted (e. g., K or NO₃ in the case of plants or K or the ion NH₄ in the case of bacteria) so that a malnutrition or a deficiency disease follows, it can not be stated that the organism suffers from the toxic effects of the salts left in the solution (as in the case of a pure NaCl solution of a sufficiently high concentration) but it suffers because the missing elements are indispensable building stones in the construction of the complicated compounds of the organism. The writer is not aware that anybody has proved that NO₃ or K or PO₄ in the nutritive solution of a plant are merely needed to overcome the toxic effects of the rest of the constituents of the nutritive solution; while in the case of *Fundulus* the experiments with distilled water show directly that the egg does

not depend for the building up of an embryo upon any of the salts contained in the sea water or any other physiologically balanced solution.

In the writer's opinion the last sentence in Dr. True's note should read as follows: A deficiency of nutritive salts deprives the organism of some of the necessary building stones for the construction of its specific complicated compounds, and this deprivation may result in the formation of inadequate or directly injurious compounds, causing the phenomena of malnutrition or of the "deficiency diseases."

THE ROCKEFELLER INSTITUTE
FOR MEDICAL RESEARCH,
NEW YORK

THE TYPICAL CASE EXEMPLIFIED¹

I RECEIVED three offers when I came up for my degree; two from institutions in the east and one from a typical state university in the northwest. The opportunities for scholarly work were pictured to be as great by the western university as by the two eastern, and the former offered me considerably more in salary than either of the latter. Everything else being equal, the difference in salary decided the case. I came west, was disillusioned, and now wish that I had chosen differently; but, by the light that I had to follow, I could not have made a different choice. Therefore, it is with the purpose of casting some new light upon the offers that come from the west that I now write.

In general, the positions out here seem more attractive than those in the east, because usually the beginning salaries are higher—the fact that the maximum salary is much lower is overlooked or disregarded; and because usually the opportunities for scholarly and research work are represented to be as large. Or, rather, I should say, misrepresented, for all the time that I have had for original work I have taken from my sleep and recreation.

In the correspondence that I had with the head of my department and with the president of the university in reference to the position,

¹ See the letter by Professor Edward C. Pickering, *SCIENCE*, February 19, 1915, p. 288.

² *Pflüger's Archiv*, CVII, p. 252, 1905; *Biochem. Zeitschr.*, XLVII, p. 127, 1912; *Jour. Biol. Chem.*, XIX, p. 431, 1914.

they spoke glowingly "of the opportunities in a comparatively new institution in a rapidly growing section of the country," and assured me that "every facility will be given you to continue your research work." My program as outlined by mail was reasonably light; but when I came to assume my duties I found that I was expected to grade all the quiz and examination papers. Consequently a great part of my time during the first year was spent with the blue pencil. In my correspondence pertaining to the position this sentence appears: "Graduate or advanced student assistance will doubtless be furnished," if I should become unduly burdened with academic work. I have made several requests for assistance, but so far have been denied it.

Nevertheless I was determined to keep the pot boiling, and I was, after a short delay, at work upon a minor problem. My first requisition for apparatus was granted immediately. I was forced to wait three months for my second; and when I made my third request I was asked the startling question, "Are you conducting personal research?" If so, I should have to meet personally the expenses of such work. I could not answer the question at first, for I did not know what personal research was, never having heard the phrase before; but when I learned that work which is self-initiated is personal, I realized that my work belonged to that category. The officer of administration with whom I had this conversation tried to show me that it was an imposition on my part to make this request. Why! had he not done research in San Francisco, in Omaha, in Chicago, in New York, yes, and in London and Paris too—the results of which, he informed me, were published in pamphlet form—and he did not request or expect the university to pay his expenses. So my third requisition was refused. This attitude toward original work is characteristic, and is not due entirely to ignorance of scholarly work, but in part to the importance and emphasis that the university gives to its correspondence and extension work.

These departments receive very liberal support. Courses are given in nearly every subject, and nearly every member of the faculty

gives some of his time to extension work; some men give their entire time to it. The extension department is probably the most important in the university. This is due to the fact that the popular lectures which are given by the faculty upon their extension tours offer the best means of gaining the people's good will. Here, where the university and the agricultural college exist as separate institutions, there is much need of this. Public favor means appropriations. Therefore it is not research but extension work that the administration desires.

One's endeavors upon the extension platform soon receive recognition and promotion, whereas research work is disregarded. It is not wanted; it is not encouraged, no matter what may be said to the contrary. I have talked the matter over with several members of our faculty, with men who have been here for eight and ten years, and they agree with me—in fact I have advised with them in writing this letter—that there is no future here for a man with scholarly ambitions. And the pity of it all is that there are many men who have no desire to continue research after their doctorate, and who would be supremely happy in these positions, where the work is new, where the people are eager for knowledge, and where no one is critical; but the administration, by feigning to hold certain ideals, attracts and elects men to the faculty who are entirely out of sympathy with the conditions of their work as soon as they discover them. The man who comes imbued with the spirit of research and who desires to continue his scientific investigation will struggle hopelessly for a year or two against the odds, and will then resign; either resign his position and return east, or resign his scholarly ambitions. If he return east he must start again at the bottom; if he remain at his post he will be discontented in the sacrifice of his ideals—a victim of dry rot.

I feel rather strongly in this matter because I am myself at the parting of the ways. I too must "resign." Which course I shall pursue is a question that is giving me no little concern. It is one, also, that I feel should never

have been forced upon me; but it is one that all who have come out here, with ideals such as mine, have been forced sooner or later to meet. The issue should have been placed squarely before me two years ago when I was considering the position. Had I then known that research was practically impossible I should never have come to the northwest. One can never learn the true conditions of an appointment from correspondence with the administrative officers. They are naturally biased. For that reason I have written this letter. I sincerely hope that it will enable others to choose less blindly than I.

X.

A TYPICAL CASE

PROFESSOR ——— graduated at ——— University and, taking a postgraduate course, received the degree of Ph.D. He then went abroad, studied at ——— University, and returned to America, full of enthusiasm for original research. He had published an important memoir for a thesis which was well received, his instructors encouraged him and his fellow students appreciated and were interested in his work.

He now received an offer of a professorship in a small country college, married and began his new life, expecting to continue his investigations. He soon found that almost all his strength was consumed in teaching, and was horrified at the end of his first year that his salary had not been increased, as had been promised upon satisfactory service. This induced him to review his forces and readjust to the situation. He assumed a more sympathetic attitude toward the tyro and looked deeper into the organization and purposes of the institution. He began to fall in with the teaching problem and reduced the expenses of his department by taking a larger number of classes himself and for a nominal sum employed a few bright upper classmen a few hours weekly to do the drudgery. He attacked the problem of efficiency in instruction and found himself well equipped for the undertaking, for the machinery of his superior training gave a diamond point to his drill in the form of system and habits of thought, and

this was backed up by the battering-ram of a growing enthusiasm.

He also became interested in the historical and vocational aspects of his subject and began to relate himself and his work to the world he lived in. In process of time his ideas began to show themselves in increased comfort and efficiency in the lives of human beings. His teaching task was now a magnet to all his powers, while his classes forgot their examinations in the joy of their daily lessons.

On the Olympic heights of the university he had learned to despise the rôle of the stumpy farmer and faithful wife who were responsible for his birth and education and much of the ethics of that parental pair had become a mere convention or a timely expedient. But there stole into the years of the busy Ph.D. a renewed conviction of the high worth of social purity, and his fictitious ideas of temperance, kindness, etc., gave way to principles more in keeping with his earlier teaching, while he ceased to despise the ultimate source of his bread and butter.

The finding of such men as this—men adaptable to the highest needs of the small country college—would be a worthy object for a Committee of One Hundred.

FORT COLLINS, COLO.

SCIENTIFIC BOOKS

Animal Experimentation and Medical Progress. By WILLIAM WILLIAMS KEEN, M.D., LL.D., professor emeritus of surgery, Jefferson Medical College, Philadelphia, with an Introduction by Charles W. Eliot, LL.D., president emeritus of Harvard University. Boston and New York, Houghton Mifflin Company, The Riverside Press, Cambridge, 1914. Pp. xxvi + 312.

In this book Dr. Keen has brought together the thirteen papers on experimentation which he has published in various periodicals during the past twenty-nine years. Nine of these deal chiefly with the contributions which this method of research has made to medical—and chiefly surgical—progress, while the remaining papers are devoted to the antivivisectionists and what they have been doing. Not him-

self an experimenter, but convinced beyond recall of the absolute necessity of animal experimentation, the author is a veteran in its propaganda, and no one writes with fuller knowledge of the facts on both sides, with keener conviction of the correctness of his position, and with a more trenchant pen. With him it is "a common-sense, a scientific, a moral and a Christian duty to promote experimental research," just as "to hinder it, and still more, to stop it would be a crime against the human race itself, and also against animals."

The eminence of Dr. Keen as a surgeon adds all the more value to his opinion of the benefits which human surgery has derived from experimentation. A striking chapter in the book is that on modern antiseptic surgery and the rôle of experimentation in its discovery and development. It gives a graphic picture, first of the pre-antiseptic surgery with its terrors of suppuration, secondary hemorrhage, erysipelas, lock-jaw, blood poisoning, gangrene and high death-rate—a picture all the more graphic because of the author's experience with its realities; then of Lister's work, with his experiments upon one horse and one calf; and finally of the results, with the virtual elimination of the disastrous sequelæ of operations, the extraordinary reduction in mortality, and the wide extension of surgical treatment to formerly forbidden fields. Shortly after the battle of Gettysburg the author was called in one night to five cases of secondary hemorrhage; since 1876, when he began the practise of the antiseptic method, he has not seen as many such cases in all the years that have elapsed, nor has he seen a single case of hospital gangrene. Formerly healing by "first intention" was so rare that its occurrence was regarded as a triumph; now its absence is a disaster. Formerly a famous surgeon lost two out of every three of his patients after the operation of ovariectomy; now the mortality is often less than one per cent. The skull cavity and the abdomen with its organs were once avoided by the surgeon; now they are fearlessly entered. "The only question," says the author, "is, should Lister have made this final test first on a horse and a calf, or on two

human beings? Can any one with a sane, well-balanced mind hesitate as to the answer?" "In the past thirty years," he continues, "experimental research has produced a more fruitful harvest of good to animals and to mankind than the clinical observations during thirty preceding centuries."

To the present reviewer that aspect of the antivivisection agitation that is by far the most interesting is the psychology of it. It is characterized preeminently by an exaggerated love for animals, woeful ignorance, a proneness to make strong pronouncements without adequate knowledge, a disregard of facts, a lack of logical reasoning, a tendency to pervert the truth and to ascribe unworthy motives to scientific men, and a general lack of moral balance in propaganda. These qualities have been demonstrated so frequently that they have come to be expected as a matter of course in those who oppose the practise of animal experimentation. As a fact it is rare that one fails to find some of these qualities in all such persons. Dr. Keen has been impressed by this and he states the attitude of many of us when he says: "I have been compelled to conclude that it is not safe to accept any statement which appears in antivivisection literature as true, or any quotation or translation as correct, until I have compared them with the originals and verified their accuracy for myself."

The four chapters here devoted to the antivivisectionists are entitled "Misstatements of Antivivisectionists," "Misstatements of Antivivisectionists Again," "The Influence of Antivivisection on Character" and "The Antivivisection Exhibition in Philadelphia in 1914." These papers teem with specific instances illustrative of the peculiarities of the antivivisectionists, many of them dealing with the classical, oft-quoted examples of supposed barbarities of the experimenters. To any one who has read of these and who supposes them to be as charged in the indictment, the reading of the present book is highly recommended, for it shows how often and how wickedly the truth has been perverted for partisan purposes. Dr. Keen handles without gloves the opponents of scientific progress.

No one, in America at least, has been more roundly denounced by them, yet this denunciation, it may be mentioned incidentally, results in making him all the more cheerful. No earnest and unprejudiced seeker after the truth can turn from the perusal of this book without a feeling of disgust at the iniquitous kind of warfare that has been waged by the enemies of progress and without a keen recognition of the utter feebleness of their attitude. In relentlessly exposing them Dr. Keen deserves the gratitude of all men and women who love truth and humanity.

FREDERIC S. LEE

COLUMBIA UNIVERSITY

An Introduction to the Study of Physical Metallurgy. By WALTER ROSENHAIN, B.A., D.Sc., F.R.S. New York: Van Nostrand Company. 390 pages, 6×9. Illustrated. Net \$3.50.

The book is divided into two parts, the first section dealing with the structure and constitution of metals and alloys, the second with the properties of metals as related to their structure and constitution.

Taking up first of all the microscopic examination of metals, the author discusses the preparation of specimens, and the microscope used, then the microstructure of pure metals and alloys. This is followed by the thermal study of metals and alloys, the thermal diagram and its relation to the physical properties. Typical alloy systems are exemplified by the lead-antimony, lead-tin, zinc-aluminium, zinc-copper, tin-copper and certain ternary alloys, followed by the iron-carbon system.

The second part first reviews the mechanical testing of metals, the effect of strain on the structure, heat treatment, mechanical treatment and casting, and ends with a discussion of defects and failures.

To review the contents of this book thoroughly would take many pages, because the author has covered the broad field of metallurgy so thoroughly and so well. This is particularly true of the presentation of the comparatively new ideas on the structure of metals, the effects of strain and of annealing, developed from Beilby's amorphous metal

theory. The elongation of the crystals when strained, the production of slip-bands and their nature, the formation of amorphous layers and the hardening of metals by cold work, twin structure, fracture under tensile, shock and alternating stress conditions, the amorphous cement theory, are all most clearly set forth. The criticisms therefore must be on minor points and not on the broad lines of the book.

For example, on page 13, after mentioning the names of the earlier workers, Sorby, Martens, Osmond, Werth, Grenet, Charpy, Le Chatelier, Heyn, Wüst, Tammann, Andrews, Arnold, Roberts-Austen, Stead, Howe and Sauveur, the author says: "The fact that the present author was privileged to count Roberts-Austen and Osmond amongst his personal friends, and that Arnold and Stead are still actively at work in this field, serves to show how very recent the whole development has been." Besides Arnold and Stead, many of those mentioned are "still actively at work" as current literature in the metallographic field amply proves.

On page 21, in describing the preparation of specimens for polishing, "the necessity of gripping the specimen in the vise" to file it is mentioned. Most people grip the file in the vise and rub the surface of the specimen on it.

On page 31, the reference to etching reagents is too short and might with advantage be expanded.

On page 162, as Ruff's work is mentioned, reference ought also be made to that of Witorf and of Hanemann.

The photomicrographs are all well chosen and excellently executed, but lose somewhat in not having a title beneath each, rather than in the list of plates.

In conclusion, the only change that could be suggested is in the section on the thermal diagram which should contain those diagrams showing partial solubility in the liquid state. A short classification according to solubility in both liquid solid states would help.

The author has succeeded in preparing an excellent book, interesting to the student, valuable to the metallurgist and engineer, and full of ideas for any one engaged in metallographic research. It is a book that can be

recommended to the general reader also, because the style is simple and the ideas are clearly and logically developed and followed. With the growing interest in metallography as a method of testing and of research it will undoubtedly prove very popular.

W. CAMPBELL

SPECIAL ARTICLES

THE TEMPORAL FOSSE OF VERTEBRATES IN RELATION TO THE JAW MUSCLES

ABOUT two years ago one of us (Gregory) discovered that the superior and lateral temporal fenestræ of all two-arched reptiles and the single fenestra of all one-arched reptiles appear to be related to the jaw muscles in such a way that they either give exit to them upon the top of the skull or afford room for them at the sides. It was afterward learned that Dollo¹ had reached the same conclusion in 1884, but his important results have been practically ignored in the subsequent literature of the temporal fenestræ, which have been considered too largely from a purely taxonomic viewpoint and too little with reference to their adaptational significance.²

More in detail, the steps leading to the present note were chiefly as follows:

It was observed that the temporal fossæ of *Cynognathus* and other Theriodonts present close resemblances to those of primitive mammals and it thus seemed highly probable that in these reptiles the sagittal and occipital crests, together with the zygomatic and post-orbital borders, bounded the homologue of the mammalian temporalis muscle. Comparison with the snapping turtle *Chelydra* suggested that in this case also the backwardly prolonged sagittal crest served for the attachment of the temporalis; and this gave added significance to the immense temporal fossæ and massive

mandible of *Chelons*. The partial excavation of the dorsal roof over the temporal muscles in *Chelydra* appeared to give this muscle more room for action, and the almost complete removal of the temporal roof in *Trionyx* seemed to give further evidence in the same direction.

In *Sphenodon* it was seen that the borders of the superior temporal fenestræ apparently served for muscle attachment, and dissection of a specimen of this animal showed that this inference was correct, and that the lateral temporal fenestræ gave room for the expansion and contraction of the voluminous muscle mass. It was further recalled that in the most primitive Tetrapoda (stegocephalians and cotylosaurs) as well as in primitive Osteichthyes (*Polypterus*, Devonian Rhipidistia, Dipnoi, etc.) the temporal region is completely roofed over, while modernized forms such as Urodeles, Anura, lizards and snakes have the outer temporal roof reduced to slender bars or even entirely absent. The presence of a sagittal crest in *Amphiuma* indicated that in the modernized Urodeles the temporal muscles had extended on to the top of the skull. From such observations the following inferences were drawn:

1. That in primitive vertebrates the chief temporal muscle-mass (adductor mandibulæ of sharks) was originally covered by the dermal temporal skull-roof.

2. That in modernized Amphibia and Reptilia, as well as in birds and mammals, one or more slips of the primitive adductor mass had secured additional room for expansion by perforating the temporal roof either at the top or at the sides or in both regions at once; much as in hystricomorph rodents a slip of the masseter has invaded the region of the infra-orbital foramen, so that it now extends through a widely open arcade and finds room for expansion on the side of the face.

3. A comparative study of the skull of *Tyrannosaurus*,³ in connection with the above-mentioned observations and conclusions, led to the suspicion that the antorbital fenestræ of

¹ "Les Muscles éleveurs de la Mandibule et leur Influence sur la Forme du Crâne: Cinquième Note sur les Dinosauriens de Bernissart," *Bull. Mus. Roy. Hist. Nat. Belg.*, Tome III., 1884, pp. 136-146.

² A partial exception to this statement is afforded by Professor Lull's well-studied reconstruction of the cranial musculature of *Triceratops* (*Amer. Jour. Sci.*, Vol. XXV., 1908, pp. 387-99).

³ Partly embodied in Professor Osborn's memoir on *Tyrannosaurus*, *Mem. Amer. Mus. Nat. Hist.*, N. S., 1912, Vol. I., Pt. I.

dinosaurs, phytosaurs, pterosaurs, etc., were also functionally connected with the muscles of mastication; but it was realized that proof of this view required a wider study of the jaw muscles of living reptiles. It was afterward found that Dollo (1884) had suggested that the antorbital fenestrae of extinct reptiles were filled by the pterygoid muscles.

4. With regard to the supposed relations of the mammals with the Theriodont reptiles, it was thought that some light on the origin of the mammalian alisphenoid and pterygoid and on the probable steps in the transformation of the reptilian into the mammalian condition could be obtained by a study of the muscles of the pterygoid region in existing reptiles and mammals.

5. The supposed transformation of the reptilian quadrate, articular and angular, into the mammalian incus, malleus and tympanic, respectively, as held especially by Gaupp,⁴ Gregory,⁵ Broom⁶ and Watson,⁷ might, it was thought, be further elucidated by a careful reconstruction of the jaw muscles of *Cynognathus* and by a study of the muscles of the middle ear in mammals (m. stapedius, m. tensor tympani).

6. In directing the studies of graduate students upon the structural and phylogenetic history of the skull in vertebrates it was found advantageous to emphasize the functional meaning and importance of the chief openings in the skull, and to consider the osseous elements in the temporal and pterygoid regions as if they were mere remnants, or tracts of bone, resulting from the reduction of an originally continuous dermal covering, through the moulding influences of the jaw muscles.

7. In comparing the skull patterns of the oldest Osteichthyan fishes (Dipnoi, Rhipidistia, etc.) sutures came to be regarded as loci of movement or progressive overgrowth, conditioned in part by muscular action, while

centers of ossification were considered as loci of relative stability.

At this point the junior author of the present note undertook to make a broad and at the same time sufficiently detailed study of the jaw muscles of vertebrates, partly with the view of testing and extending the foregoing observations and conclusions.

It was soon found that while many anatomists had made intensive studies of the innervation of the muscles of mastication in certain types very few had attempted to follow them throughout the vertebrates and no one had given an adequate series of figures. It is indeed a surprising fact that comparative myology is so briefly treated in the standard textbooks. The work has been carried on in the laboratory of vertebrate evolution in the American Museum of Natural History. A series of 26 existing types of vertebrates has been studied and figured as follows: Elasmobranchii 1, Chondrostei 2, Holostei 1, Teleostei 3, Crossopterygii 1, Dipnoi 1, Urodela 3, Anura 1, Chelonia 1, Rhynchocephalia 1, Lacertilia 2, Crocodilia 1, Aves 1, Mammalia 7. In each case special attention has been paid to the innervation of the muscles as a guide to homologies. By means of these data, and of the principles that became apparent as the work proceeded, reconstructions of the jaw musculature were attempted in the following series of extinct forms: *Dinichthys* (Arthrodira), *Eryops* (Temnospondyli), *Labidosaurus* (Cotylosauria), *Cynognathus* (Cynodontis), *Tyrannosaurus* (Theropoda). The full results of this study will be published elsewhere by Adams, but meanwhile it may be worth while to record the chief general conclusions which we have reached in collaboration.

1. It seems impossible to work out the jaw musculature of *Dinichthys* either on the dipnoan or on the ordinary teleostome bases and a study of the muscle areas by Adams indicates a unique type of jaw movements, a fact of no little phylogenetic significance, in view of the disputed relationships of this group.

2. The above mentioned conclusions of Dollo and of Gregory regarding the origin of

⁴ "Die Reichertsche Theorie," *Archiv. für Anat. und Entw.*, Supplement Band, 1913.

⁵ *Bull. Amer. Mus. Nat. Hist.*, Vol. XXVII, 1910, pp. 125-143; *Jour. Morph.*, Vol. XXIV, 1913, pp. 23-35.

⁶ *Proc. Zool. Soc.*, 1912, pp. 419-25.

⁷ *Proc. Zool. Soc.*, 1914, pp. 779-85.

the temporal and antorbital fenestrae of reptiles are reinforced by much additional evidence.

3. The inferred conditions of the jaw musculature of *Cynognathus* are entirely in harmony with the views (a) that in the mammal the back part of the reptilian jaw became transformed into the accessory auditory ossicles; (b) that the basal portion of the mammalian alisphenoid is homologous with the reptilian pterygoid as suggested by Watson,⁴ while the ascending portion seems to have been derived from the epipterygoid, as held by Broom and Watson.

4. In the transitional pro-mammals the reptilian pterygoid muscles pterygoideus anterior) became greatly reduced in correlation with the reduction of the elements behind the dentary; a possible vestige of these muscles may be the tensor tympani muscle, which runs from the basicranial region to the handle of the malleus. The mammalian internal and external pterygoid muscles are only partly homologous with those of existing reptiles and represent slips of the capiti-mandibularis mass, developed as the new joint between dentary and squamosal became established. The loss of the descending flange of the reptilian pterygoid, the secondary separation of the pterygoids along the mid-line and the transformation of the reptilian transpalatine into the true mammalian pterygoid (as held by Watson) all become more intelligible when considered in connection with the above-described changes in the musculature.

5. As a working hypothesis it is assumed that the transformation of certain elements in the temporal and occipital regions of early Tetrapoda was partly conditioned by the stresses induced upon the skull roof by the jaw and neck muscles. Comparison with lizards, *Sphenodon*, etc., clearly indicates that the prolongation of the parietal into a postero-external process joining the true squamosal was correlated with the squeezing effect of the capiti-mandibularis and depressor mandibulae muscles. This may also be responsible for the appression and coalescence of the supe-

rior and lateral temporal elements (supra-temporal and squamosal), in the early reptiles. The shifting of the post-parietals (dermo-supraoccipitals) and tabularia from the dorsal to the posterior aspect of the occiput was no doubt influenced also by the forward growth of the neck muscles upon the occiput.

W. K. GREGORY,

L. A. ADAMS

AMERICAN MUSEUM OF NATURAL HISTORY

THE AMERICAN ASSOCIATION FOR THE
ADVANCEMENT OF SCIENCE
SECTION D—MECHANICAL SCIENCE AND
ENGINEERING

THE first session was held in the morning of Wednesday, December 30, in the engineering building, Vice-president Frederick W. Taylor and Dr. Charles S. Howe in the chair, with an attendance of about 130. It was announced that the sectional committee had recommended for election to the general committee for the office of Vice-president, Dr. Bion J. Arnold, of Chicago. The following officers were elected by the section:

Member of Council—Dr. Rudolph Hering, of New York City.

Member of General Committee—Morris L. Cooke, of Philadelphia.

Member of Sectional Committee—Dr. Charles S. Howe, of the Case School of Applied Science.

The program of the session was as follows:
Principles of Scientific Management: DR. FREDERICK W. TAYLOR.

Which is to Control Public Works—a Board or a Single Head? MORRIS L. COOKE.

The Improvement and Enlargement of Transportation Facilities: GEORGE S. WEBSTER.

A Study in Cleaning Philadelphia's City Hall: WILLIAM H. BALL.

Every city, town and hamlet which owns a public building of any kind is confronted with the problem of efficient and economical cleaning. Public buildings are constantly growing in size and it is becoming more and more possible to handle the problems of their maintenance and operation on a technical basis. The fact that after what must be admitted to have been a crude study, extending over only a few months, we were able to effect economies amounting to over \$30,000 a year, or \$100 a day, in the cleaning of one public building, shows the possibilities. According to technical and other literature the cleaning of public buildings has been given very little

⁴ *Ann. Mag. Nat. Hist.* (8), Vol. VIII, Sept., 1911, pp. 822-23.

consideration, particularly from an engineering standpoint.

We must look to the development in this field of definite standards as to both appliances and methods. This standardization must be of such a character as to be applicable wherever work of this kind is done. Most of our present appliances and materials are crude and the outgrowth of almost no study that could be called scientific. While there are undoubtedly inherent difficulties in handling the personnel on the same basis that they are handled in industrial establishments, improvement in this direction has been so rapid in the last few years that we have every reason to look forward to further radical improvements in this direction.

It should be pointed out that there are no inherent differences between the cleaning of private buildings. Therefore, in looking at the whole problem of cleaning buildings, and judged by what it means both in dollars and cents and in the comfort of the occupants, the problem is a proper one for engineering attack and solution.

Experience in Locating and Mapping Pipes and Valves in an Old Water Works System: CARLETON E. DAVIS.

The necessity for complete plans and records of pipes and valves in a water-works system is evident. In many cities, too much dependence has been placed upon the memory of employees and too little stress has been laid upon the importance of accurate and enlightening records so distributed as to be immediately available by as many employees as possible.

In the definite scheme of obtaining and recording such information, much spare time of employees can be used in obtaining data without adding to the general expense. The city of Philadelphia is operating such a system with reasonable success.

New Water Supply Conduit of the City of Hartford Water Works: CALVIN MILLS SAVILLE.

The development of a new water supply for the city of Hartford, Conn. (pop. 131,000 in 1914), comprises a collecting and storage reservoir, located 14 miles from the city, with a capacity of 9 billion gallons; a compensating reservoir of 3 billion gallons to compensate mill owners for the stream flow taken for the collecting reservoir; a pipe line, conduit and tunnel from the collecting reservoir to one of the existing distributing reservoirs; a filtration plant and a large size main supply line from the distributing reservoir to the city.

This paper tells in detail of the construction of the 3,667 feet of concrete conduit, 2,333 feet of

concrete lined tunnel, and 39,660 feet of 42-in. cast iron pipe line. The conduit is of horseshoe section, cut and cover type 5 ft. \times 4.75 ft. vertical and horizontal dimensions. Some excavation as deep as 30 feet in the overlying glacial drift was necessary. The construction of the tunnel was preceded by complete diamond drill borings. The geological structure encountered was a basalt lava flow overlying the Connecticut red sandstone.

The construction of the 42-inch cast iron pipe line 7½ miles long is fully described. The canvass of the bids is given, and an unusual way of discriminating between bids for furnishing steel and cast iron pipe, whereby 15 per cent. was added to all bids received for steel pipe.

Latest Advances in Inoffensive Sewage Disposal: RUDOLPH IERING.

The paper covered the latest advances made towards obtaining an inoffensive collection and disposal of sewage, which has now reached practically satisfactory solutions for nearly all possible cases.

The chief means to prevent all foul odors in the collection of sewage are to maintain (1) a continuous flow and no deposits and retentions of sewage, (2) a frequent flushing and (3) a free air circulation in all sewers.

A large number of sewer systems with these means now continuously deliver an inoffensive sewage.

The means for an inoffensive final disposal of sewage depend on the local possibilities. In nearly all cases the solids and liquids require separate treatment.

1. In sufficiently large masses of flowing water. The liquids can be dispersed in them in well known proportions so that no offense is possible and so that automatic oxidation of organic matter takes place. The solids can be retained and, according to their quantity and character, can be treated economically and inoffensively in efficient ways.

2. On land. The liquids must be oxidized by sufficiently extensive thin film surface contact with bacterial slime, as by percolation through sand, gravel or broken stone, the surfaces of the grains being well covered with slime, and well exposed to air circulation. The oxidation of all organic matter may thus be graded in degree and always be inoffensive.

The solids must be collected under water in tanks under conditions preventing putrefaction, but which cause a sufficient decomposition by bacteria producing chiefly methane gas and carbon dioxide, both inoffensive, and a final sludge re-

sampling humus soil in forests, also inoffensive. This has been made possible by the recent extensive introduction of Imhoff tanks. Quite recently it has been found that a daily mechanical agitation of the sludge and always maintaining its alkalinity, materially hastens the decomposition.

Operation and Efficiency Reports from Water and Sewage Purification Plants: RALPH E. IRWIN.

In Pennsylvania the state commissioner of health is required by law to give a permit for the construction of all water purification plants supplying water to the public for domestic purposes and for all municipal sewage treatment plants. To intelligently issue a permit for the construction of such plants it is necessary to have detailed information concerning the efficiency, manner of operation and construction of existing plants. The commissioner has, therefore, created a section in the engineering division which, under the direction of the chief engineer, inspects and tests plants already in operation.

Operation and efficiency reports should be submitted to the commissioner of health:

1. That the commissioner may know accurate records are being kept by each plant.
2. To give information for answering complaints from those served.
3. To assist in locating the cause of water-borne disease apparently due to public water supplies.
4. That information may be at hand from all parts of the state, thus forming a clearing house for information from plants treating similar waters or sewages and make it possible to indicate the most efficient and economical method of treatment when considering improvements, or the construction of new plants.
5. To allow checking results from one plant with another to show inaccuracies or carelessness.
6. To give information for interpreting results of analyses submitted by plants, those served, or results of samples analyzed at the commissioner's laboratory.
7. To give information upon which to base suggestions for the prevention of waste of chemicals, wash water, etc.
8. To assist in judging the efficiency of operators in charge of plants.
9. To have records at hand showing when inspections and tests are necessary and to assist in this work.

At the present time in Pennsylvania there are 115 water filtration plants and 91 sewage treatment plants in operation. Also, there are a large number of chemical dosing plants installed for the dis-

infection of dangerous water supplies and insufficiently treated sewage.

The New York Sewage Disposal Experiments and Plant at Brooklyn, N. Y.: GEORGE T. HAMMOND.

The experiment plant described in this paper was authorized by the Board of Estimate and Apportionment of the City of New York, \$50,000 being provided to cover the cost. One of the most difficult sewage disposal problems which the city must solve is afforded by the rapidly progressing pollution of Jamaica Bay—a tidal reservoir 19.28 square miles in area and very shallow, the situation of an important oyster industry. The population contributing sewage to this bay is 250,000 persons, of whom 210,000 are in Brooklyn. The sewers are on the combined plan and discharge 18,000,000 to 22,000,000 gallons of dry-weather flow into the bay daily. Storm-water flow from the sewers at times reaches over 1,000 cubic feet per second and is very foul. One of the principal purposes of the experimental plant is to find the best means of treating this sewage.

The plan of the experimental plant provides for pumping the sewage to an elevated supply tank, from which it is fed by gravity to the experimental units. The amount of sewage used by the plant is about 1,200,000 gallons per day. The experimental plant includes three Imhoff tanks of varying size and depth; six sprinkling filter beds; one tank-aerator for treatment of sewage with compressed air supplied by an air compressor; one siphon-aerator, which treats sewage by compressed air, which is supplied by the flowing stream of sewage through a hydraulic air compressor siphon; one gravel strainer, or roughing filter; four settling or sedimentation tanks; six secondary sedimentation tanks; ten sludge drying beds of the Imhoff type. Various types of screens, including a Riensch-Wurl screen. Various experiments are also provided for the disinfection of sewage effluents and for various methods of treating and disposing of sludge and screenings. All of the units of the plants are constructed on a working scale, each one large enough for testing the actual operation conditions of a full-size plant.

Some Considerations Affecting the Disposal of Sewage at Seaside Resorts: MARSHALL R. PUGH.

For a distance of approximately one hundred and twenty-five miles the coast of New Jersey has an almost continuous line of summer resorts, some large and some small. Some of the considerations theoretical and constructive, affecting the disposal of sewage at seaside resorts may be briefly stated as follows:

The Collecting System.—(1) Use self-cleansing velocities where possible, but do not be bound by them when they result in a cost incommensurate with their benefits. (2) When self-cleansing velocities can not be wisely adopted, make adequate provision for flushing. The sewers must be kept clean.

The Disposal Plant.—(1) The plant must be adapted to great seasonal variations in flow. (2) The capacity of the ocean to digest and purify the sewage, being the most economical and effective means of attaining this end, should be made use of. (3) Where bathing is an asset, the discharge of crude sewage to sea is not permissible. (4) Single-story tanks furnish in general the method best adapted to treating the sewage of resorts before its discharge to sea. (5) Nuisances from such effluent do not arise if tanks and appurtenances are correctly planned and the discharge effected through a properly designed outlet, at a sufficient distance from shore, and in ten feet or more of water. (6) It would appear from what evidence we now possess that no ill effects to health result from the proper discharge of such effluent. (7) Owing to the difficulties encountered in work along the coast and under the surface of the ocean, careful consideration must be given to durability and to the means of executing the work called for by the plans.

Preservation of Wood: P. A. MAIGNEN.

The railroads are said to spend \$121,500,000 a year in cross ties. If all these ties were treated properly by a good preservative process, it would be possible to save more than \$450,000,000 in 25 years. Wood is composed of two principal parts, cellulose and sap. Cellulose resists decay a long time. The decay begins in the sap and extends to the cellulose. It is therefore urged that some ways and means of removing the sap from the wood be found. Many attempts have been made to render the sap proof against decay without removing it, but the result has not been satisfactory.

The preservatives used in the United States in 1913 were: 108,373,359 gallons of creosote; 26,466,803 pounds of zinc chloride, and 3,885,758 gallons of other preservatives. In that same year there were 153,613,888 cubic feet of timber treated by all preservatives. Of the creosote used only 38 per cent. was produced in this country and 62 per cent. was imported.

At present 80 per cent. of the railroad ties are treated. If a satisfactory method of impregna-

tion could be devised so that the wood could get the full benefit of a thorough penetration it would not be long before all the ties would be treated. Unfortunately the impregnation, as carried out now, does not penetrate the wood sufficiently. In experiments it was found that one specimen from which the sap had been removed was impregnated throughout the whole length of the wood; whilst the other specimen of the same kind, but whose resins had not been extracted, was impregnated not more than a few inches from each end.

The second session was held on the afternoon of Wednesday, December 30, Vice-president Dr. Frederick W. Taylor and Mr. O. P. Hood in the chair, with an attendance of about 95. The program of the session was as follows:

Municipal Highways—a Problem in Maintenance:

WILLIAM H. CONNELL.

The three foremost problems involved in the operations of a highway department are: Organization, maintenance and construction.

A good organization is essential particularly in so far as maintenance is concerned, as it is practically impossible to continuously and systematically maintain pavements and roads in first-class condition, in an economical manner, without a good working organization built up along the lines best adapted to cope with the conditions involved in this important branch of work coming under the jurisdiction of a highway department. By this it is not intended to give the impression that the maintenance organization should be separated from the construction, as separate organizations are apt to result in an overlapping of jurisdiction and a tendency to shift responsibility, and open up a field for unlimited excuses as to whether the construction or maintenance division is responsible for any unsatisfactory conditions that may arise relative to the pavements. Furthermore, it is obvious that the logical organization to maintain the pavements is the one that saw them laid and is familiar with every detail of the construction, as very often a knowledge of apparently trivial conditions in connection with the construction bears an important part in the future maintenance.

Routine maintenance includes such work as the regular street cleaning in municipalities, and the cleaning of country roads and gutters, and any other work of this character that is more or less routine and should be performed under definite schedule. The streets in the thickly populated sections of the city should be cleaned every day; in less thickly populated sections, every other day; every third day, and so on until we come to the

country roads which should be cleaned once a week, once every two weeks and some only once a month, depending upon the amount and character of the traffic which largely governs the frequency with which the cleaning should be done. The amount and schedule of work and the force necessary to perform it can be determined upon in advance and carried on in a systematic manner under a regular organization, more or less military.

General maintenance includes repairs to streets and roads, and involves different characters of work, each requiring special knowledge on the part of those engaged in the actual performance of the physical work for which special gangs have to be organized. Stone block, wood block and brick repairs, for example, require skilled laborers who have made a specialty of this work and are employed under the title of pavers and rammers; while repairs to asphalt and bituminous pavements must be performed by men specially skilled in this line of work, in addition to the necessary force engaged at the mixing plants. Macadam road repairs, the care of earth roads, and bituminous surface treatments, also require men specially trained, and while it is desirable to train the gangs for each particular branch of this work, such, for example, as bituminous macadam built by the penetration method, water-bound macadam, bituminous surface treatments and the care of earth roads, the three classifications, namely, block repairs, bituminous pavement repairs (mixing method), and macadam, earth road and bituminous surface treatments, represent the three branches into which the organization is usually divided.

Methods for the Elimination of Politics from Administration of Highway Departments: LOGAN WALLER PAGE.

We have a system, if it may be called such, of public roads approximating 2,300,000 miles. The people as a public corporation are yearly consenting to the expenditure of about \$200,000,000 in a haphazard endeavor to make this vast road investment pay. That it is a losing investment, conducted on lines directly opposed to those of the best managed private corporations, is an established fact. It is estimated by road experts who have made a careful study of the various phases of the road question, that the American people yearly lose at least \$50,000,000, directly and indirectly, because of their careless supervision of these traffic facilities.

State supervision seems to be the first and most effective step toward obtaining satisfactory road

conditions. But there are certain evils for which the people of the state should provide safeguards in planning their system of state road management: First, the appointment in each unit or subdivision of only that number of road officials necessary to do the definite duties required of each in that unit, and the necessity for distinct placing of responsibility for work done. Second, some arrangement should be made whereby the road officials shall give the roads continuous and systematic attention, instead of the existing irregular care, which has proved so costly in the long run. Third, the requirement of necessary qualifications which the road official must possess to discharge his duties efficiently. Fourth, the demand that wherever practicable the incumbent of any road office shall be appointed because of his qualifications, in this way avoiding election of those who may prove more able politicians than engineers. Fifth, road officials would best serve the people if the term of office were limited by merit, and not terminated at regular periods. Sixth, provision should be made for a careful study of traffic needs in the individual localities so that political considerations may not be the deciding factor in the location of road improvement, distributing of appropriations, and appointing of needed officials.

Illinois has recently made a notable advance toward centralizing road control, and the placing of men on merit, as each county engineer takes a competitive examination, and is made an assistant to the state highway engineer, thus providing correlation and centralized oversight. In fact, the whole trend of state participation has been toward placing a broader scope of duties and authority in the central state department. This continued trend, it is hoped, will be one of the main factors in solving the problem of supervision, while the intelligent application of the merit system in securing this skilled supervision in road work is the only promising method of eliminating politics from road administration.

Plant Inspection for Pavements: JULIUS ADLER.

It has been a recognized fact that the complete inspection of any engineering structure begins with the materials to be used in that structure, and it is safe to say that this statement applies with full force to street and roadway pavements, in which such a wide variety of materials is now being used, and in which the life of the structure depends so very largely upon the strength, durability and suitability of the materials in resisting the effects of traffic and the atmosphere. The fact, however, that so many uncertainties and diffi-

culties exist even to-day in regard to fixing the desirable qualities of many paving materials is a certain indication that this subject has not received the close study and systematic observation that its importance merits; furthermore, while there has been too great a tendency in some lines to charge all failures to the materials used, or some one of them, rather than to the methods of construction, it is also certain that a considerable proportion of failures in paving work can still be traced to the use of materials, which, if not actually of poor quality, were unsuitable for the conditions at hand.

The desirable scope of plant inspection must first be established before the actual duties and details can be determined. The work may be confined to the general inspection and sampling of materials and mixtures, requiring nothing more than that the contractor shall keep within the more or less broad limits of the specifications, but allowing him discretion and variations within these limits. Going a step beyond this idea, the inspection may be carried on as actual plant control, in which the highway organization assumes the right to specify narrower limits for a given piece of work as to amount of bitumen, hardness of the asphaltic cement, temperature of mixtures, and even to some extent the exact details of the method by which these mixtures are to be obtained. The latter plan, that is, plant control, is the logical one to follow on standard, if not patented pavements as well, from the standpoint that the organization which formulates the specifications should also be most capable of regulating their application.

Specifications Covering the Rolling of Road Crusts of Various Types: MAJOR W. W. CHOSBY.

The assumption is made that the contract and specifications are to be in the more usual form under which the contractor is "to furnish all the labor and materials and do all the work."

Before proceeding to details, it seems necessary, for the sake of clearness, to state certain general principles in regard to specifications.

In the first place, while it may be necessary sometimes to restrict in details the methods to be followed, generally it will be found more satisfactory to specify the results to be obtained rather than one exact method for reaching the result. Elasticity for meeting variations in conditions encountered will then not be wanting. This is especially true as regards rolling.

Secondly: Where necessary the methods of producing the result may be limited by specific de-

scription but this should be done only when unavoidable for the insurance of proper results and for preventing the production of a result which will be offered for acceptance as "just as good."

Thirdly: For economic reasons as much elasticity in the provisions for limits, in the descriptions of the machinery or tools allowed for use, should be given as is practicable.

Fourthly: The specification of the result to be secured should be absolutely definite, clear, and as brief as may be consistent. The specification should so describe the product that no more room for argument as to the fulfillment of the specification will exist than will be occupied by a few questions whose answers can and must be determined by scientific methods, such as physical or chemical analyses and arithmetical calculations or measurements.

The author cites the following specification covering the rolling of the second course of a macadam road as embodying the fundamental principles cited.

Second Course

"After the metal for the second course shall have been spread to the proper thickness and cross-sections, it shall be rolled as hereinbefore provided under the head of 'First Course,' except that water, in connection with the rolling, shall be used as follows: When the rolling shall have been carried on to the point where the metal of the second course will not push or 'weave' ahead of the roller and any depressions or unevennesses have been properly remedied, as provided, the rolling shall be interrupted and a thin layer of sand, screenings or other approved binding material, shall be evenly spread over the surface of the second course metal with as little disturbance of the latter as possible. The quantity of fine material so applied shall be just sufficient to cover the metal and care shall be exercised to avoid its use in excess. Water shall then be sprinkled on the roadway surface and the rolling at the same time resumed, the quantity of water used being such as will prevent the fine material from sticking to the wheels of the roller. The combined watering and rolling shall be continued until the voids of the metal shall become so filled with the finer particles as to result in a wave of water being pushed along the roadway surface ahead of the roller wheel. The watering and rolling shall then be discontinued until the macadam shall have dried out. If then the metal shall begin to loosen and to appear on the roadway surface, or if the voids in the metal shall appear to

be not properly filled, the watering and rolling shall be resumed with the application of only as much additional fine material as may be necessary. Any depressions or unevennesses appearing during the above operations shall be remedied by the contractor as hereinbefore provided, and when completed the macadam shall be uniform, firm, compact and of at least the thickness required and shall have an even surface nowhere departing by more than one inch from the grade and cross sections shown on the plans."

Life of Bond Issues for the Construction of State Highways: E. P. GOODRICH.

Financial Problems Involved in the Selection of a Suitable Type of Road or Pavement: JOSEPH H. CONZELMAN.

The most common methods of obtaining funds for highway improvements are: by general taxation, by special taxation, by assessments on those particularly benefited, by bond issues and by combinations of these methods. A large part of the work done by state highway departments is financed by appropriations from the general tax.

The paving work of many cities in the United States is paid for with money secured by assessing the abutting property. Some revenue is collected in this way in a few rural districts. Special assessments are not, however, very popular or just in these sparsely settled sections because of the large extent of abutting property owned by individuals, and the low property value. Where assessments are practicable and are paid immediately, this method is an economical means of financing highway improvements.

Bond issues have come into general use as a means of obtaining money for state and county highway work, where a large amount of construction is planned. They render large sums of money available for immediate use, making possible a large amount of improvement which probably could not otherwise be financed. Bonds have been issued, however, in many localities with little consideration of the principles of economics. Money obtained in this way has been used to build roads, parts of which, at least, have worn out long before the bonds issued were redeemable. In other instances no provision has been made for retiring the bonds.

Bonds issued for a period of years not greater than the life of the roads which are to be built, when proper provision is made to retire them, is certainly an economical method of obtaining money. The conditions in some parts of the country, for example, in the grain districts, would

seem to justify the issuance of bonds whose term extended beyond the life of parts of the highways built, if money for the work could be raised in no other way. Where fifty-year bonds are used to finance the building of roads or pavements, the fairest method, to the present and future generations, of redeeming the bonds and providing for the necessary reconstruction during the life of the bond, is that method which distributes the cost of the improvement most evenly among those deriving the benefits. The method which will most closely accomplish this endeavor must provide for the determination of the life of the several parts of the improvement, and, on the basis of this determination, distribute the cost of the improvement.

Preliminary Surveys and Mapping of National Highways: CHARLES HENRY DAVIS.

A national highway must be interstate. They must be located along the line of densest population so they may carry the heaviest traffic. This is between the large cities and those lying between them on the center line of water sheds. Fifty thousand miles of such national highways will serve, in the counties through which they pass, 88 per cent. of the urban and 53 per cent. of the rural, or a total of 69 per cent. of the people of the United States. It is here that the greatest rural population and tonnage will be served the best, not by so-called radial roads from railroad stations or towns. If a system of 100,000 miles was built, such roads would carry so nearly the entire rural tonnage as to make the balance negligible. The data for locating such a system has been secured for the forty-eight states. Seventeen have been completed, engraved and printed. Five more are ready for engraving. Every named place on these highways will be shown, whether city, town, village, hamlet, post office or otherwise. Also adjacent communities are shown. These maps will be standard and will require but little revision to keep them accurately up-to-date. The scale is such that straightening or relocating a road between two places will not require alteration of the maps. If a traffic census were taken on the alignment of such a mileage we would gain conclusive evidence as to the correctness of the above statements and thus avoid costly and fatal errors. When completed these maps will occupy a volume 5 in. \times 10 in. of only 100 pages (50 sheets 10 in. \times 10 in.) which with 44 pages of index of every named place will only be $\frac{1}{2}$ in. thick, including maps and index. When compared with maps available at present their usefulness and convenience are at once apparent.

Construction of Highways with Convict Labor in West Virginia: A. D. WILLIAMS.

The labor of the prisoner should not be exploited for the profit of a few and to the detriment of the honest laborer, but in justice to the man in prison and to society the prisoner should be given some useful and beneficial employment. This employment should be of such a nature as to give back to society in a measure stonement for the debt of transgressing society's laws, so that the prisoner will feel that he has rendered a just compensation for his own acts. The labor should be of such a class as would render the broadest service to all of the people, and not infringe upon the rights of any free laborer any more than possible. But the free laborer should not ask that society support an idle prison population so that he might monopolize all the work. The free laborer has as much right to ask a pension, and would do society much less harm in procuring a pension than in compelling the support of an idle criminal population which will turn on to society a weakened bunch of men. The prisoner for his own good must be employed. This labor should be given upon some class of property or the improvement of some class of property held in common by all the people. Therefore, improvement upon the public roads is a class of development that benefits everybody. This is public property, improved for public advancement, and the prisoner being a public charge can here be justly used for the public's good.

The great good that can come to the public from the use of any prisoner or prisoners is not his labor, but is the improvement of the individual by making of him a useful and beneficial citizen. An investigation on the part of the writer reveals that men or prisoners worked in the open air under a system wherein appeals can be made to the better manhood in their natures make better citizens than those employed in confinement.

West Virginia has a law which provides that the prisoner may elect to labor prior to his trial in case he is denied bail and is unable to give bond. This is a humane step and offers an opportunity for the man who has been wrongly accused to keep up his muscles and to provide in a measure for his family while being detained. The law at the present only permits payment of 50 cents per day if released or gives a credit of \$1.00 per day on fine if convicted. The writer believes that this should be made a credit of \$1.00 in case of release. The writer further believes that prisoners who work upon their honor and give good service should re-

ceive a wage which should be retained until the expiration of the sentence or in case of needy families be given to them. Because a man has transgressed a law and is deprived of his liberty is no reason why he should not retain his responsibility to his family and society should give him this privilege because oftentimes the innocent wife and children are punished more than the man in prison.

Utilization of Short-term Convicts for Highway Work in Georgia: JAMES L. STANFORD.

To secure accurate data to form a basis for the investigation of road work for misdemeanor convicts, a questionnaire was prepared and sent to every county in Georgia and the results obtained are presented in a condensed form in this preliminary report.

The State Prison Commission reports that practically all of the misdemeanor and felony convicts, with the exception of the women and those in poor health, are employed in some phase of highway work; 2,441 misdemeanor and 2,740 felony convicts were worked by 124 counties during 1914.

Regardless of the kind of work undertaken by a convict gang, the following factors will be involved, the usual interest on the first cost and depreciation of the equipment of the annual expense of maintaining the convicts. The economical solution is to so adjust the size of road gang as to render the sum of these factors a minimum.

According to reports received and actual experience, which may be said to have passed the experimental stage, a guard can most economically and advantageously handle fifteen men. The number of units composing a gang should be proportionately determined by such factors as the expense per man, mileage of roads to be constructed and repaired, the character of the work to be done, the class of men in the gang, and the equipment provided. The expense per man both as to food and guarding at night increases rapidly as the number of men in a gang falls below thirty and decreases just as rapidly as the gang increases by units up to a certain limit. One night guard can handle a camp of ninety convicts quite easily since the day guards sleep near by and are ready to give him assistance at any time. The guards act as road foremen, hence the expense of employing foremen is obviated and balanced by guard hire. The guards should be hired at a stipulated amount and their wages gradually raised as they become more efficient foremen.

DISEASE RESISTANCE IN PLANTS¹

THE control of fungous diseases in plants may be effected in three different ways: (1) By killing the parasite before it enters the host, (2) by curing the diseased plants, and (3) by growing disease-resistant varieties of cultivated plants or making the susceptible varieties resistant. So far the first method is the one most generally followed, the means employed depending on the nature of the fungus.

It is easier to protect the host from a fungus which combines a highly developed parasitic character with alternation of hosts than from one which spends its entire life cycle on the same host. For example, when rust (*Ræstelia cancellata*) appears in a pear orchard the danger from it may be done away with by removing all juniper trees from the neighborhood, the juniper being the host for the alternate stage of the fungus (*Gymnosporangium sabinae*). The same measure may be adopted in the case of red rust of wheat (*Puccinia graminis*) in countries in which the fungus does not reinfest directly the wheat but grows in the spring on the barberry (*Berberis*). This disease has practically disappeared from Germany since the removal of all barberry and mahonia bushes from the vicinity.

The destruction of a fungus living on one host only is more difficult because of the fact that this may necessitate the destruction of all diseased plants or parts of them, an undertaking which could hardly be carried out completely. However, if carried

¹ A lecture delivered by invitation at the universities of California, Wisconsin, Minnesota and Cornell, and the Iowa Agricultural College, in October, 1914.

RECEIVED. Intended for publication and books, etc., intended for review should be sent to Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

out thoroughly and before the parasite has reached too advanced a stage of development this method may be crowned with success. A striking example of this is the control of pear blight in the Rogue River Valley, Oregon. In this region the disease has been kept within bounds, while in the Eastern States it was permitted to gain a foothold and is now a calamity.

The spraying of potatoes against *Phytophthora infestans*, by which the fungus is destroyed before it is able to penetrate the tissues of the host, may be included in this class of control measures. Another example is the destruction of the smut spores, which cling to the outer covering of the grain, in the case of stinking smut, for instance.

It is a more difficult task to cure a plant already diseased than to prevent the disease, and only in rare cases is the method of cure known, the reason for this being that plants are not organized like animals, and in most cases it is impossible to influence a central system. The cure of fungus diseases of different trees by giving the roots an abundant water supply is an example of treatment based on the principle that many fungi are unable to grow in tissues which show a high water pressure. In dry soils the water content is kept on a low basis and this favors the attacks of the fungus.

Another example of the curing of the plant is the hot-water method of seed treatment for loose smut of wheat and barley, this treatment being founded on the destruction of the fungus germs within the seed.

We now come to the third method of disease control, that is the use of disease-resistant plants. The importance of this method is well understood by both scientists and growers, but the application of the principle, it must be confessed, is in its infancy.

Utilization of the factor of immunity in disease control may be divided into two parts, that is the breeding of resistant plants and the artificial immunization of plants. From a scientific point of view, however, both of these rest on the same basis.

Before a disease-resistant race can be bred resistant individual plants must be found. It is a well-known fact that in the vegetable kingdom closely related species suffer in different degrees from attacks of the same parasite. The difference in resistance of the various species of one of our most important cultivated crops, wheat, is unusually prominent, as shown by the researches of Wawelaw. Of the eight botanical species which are generally thought to have produced the cultural varieties of our wheat, *Triticum vulgare*, *T. compactum* and *T. spelta* are attacked by red rust; *T. durum*, *T. polanicum*, *T. turgidum* and *T. monococcum* are resistant; the western European varieties of *T. dicoccum* are resistant, and the eastern varieties of Turkestan are liable to rust. *T. dicoccum dicoccoides*, which was found in Palestine some years ago and which has sometimes been regarded as the ancestor of our common cultivated wheat, *T. sativum*, is also a non-resistant species.

The varying susceptibility of species of the same genus makes it possible to substitute for highly susceptible species others of nearly equal cultural value which are less susceptible or resistant. In the case of the coffee plant very good results have been obtained by this means. It is well known that *Coffea arabica* was completely destroyed throughout the Asiatic tropics by the rust fungus *Hemileia vastatrix*. The related African species *C. liberica* appeared to be resistant to the disease and was brought under cultivation in the entire territory in which *C. arabica* had been grown and in

which coffee culture was possible. The immunity of this variety, however, proved to be of an unstable nature, and as a consequence the growers were obliged to import *C. robusta*, a species having lower commercial value, from the virgin forests of Africa. Because of the fact that *C. liberica* produces beans of much poorer quality than *C. arabica* and *C. robusta* beans of a poorer quality than *C. liberica* their substitution was of restricted value, but it saved the valuable coffee industry in some regions from ruin.

The maintenance of profits with the inferior coffee is made easier by the degeneration of taste among civilized people—the result of standardization in all branches of life. The average man to-day lacks the faculty of determining whether his beef was cut from a Holstein or a Hereford, whether the fowl on his table was fed with barley or oats, whether a wine is natural or sugared, or whether the coffee he drinks is *C. arabica*, *C. liberica* or *C. robusta*.

Even though the value of the resistant plant is lower, as in the case of the examples cited, the possibility of improving the variety still remains. Two methods may be used toward this end, that is grafting a non-resistant on a resistant variety or crossing the two. The first was followed in dealing with *Phylloxera* of the vine in Europe. The European vineyardists grafted their own highly cultivated varieties on the roots of the American vine, which latter resists the attacks of the parasite, and in this way produced a vine combining the requisite wine-producing qualities of the European vine with the disease resistance of the American vine. In view of these facts it would seem easier to replace the European vine with the American, but this is not practicable, because under European conditions of climate it is not possible to prepare wine from Amer-

ican species. The grafted vine is only an imperfect substitute, because its life is of short duration and the labor of grafting makes its culture expensive.

As the grafted vines are heavy bearers, the disadvantages from their use are not felt as keenly in France, where the aim of the viticulturist is to produce large quantities of wine, as in Germany, which aims to produce "quality wines." The really first-class wines are produced from vines which are permitted to grow only a few grapes, and this, coupled with the fact that the quality of wine improves with the age of the vine, shows that the cultivation of grafted vines is more impracticable in Germany than in France.

Another method of improving disease-resistant wild species and preparing them for cultivation is illustrated in the case of sugar cane. In the eastern part of Asia this plant, especially the high sugar-producing varieties, is subject to the so-called serah disease, the nature of which is still unknown. In British India, however, the wild resistant Chunee cane was found, but it had too much fibrous substance to be suitable for sugar-producing purposes. Several hundred crosses were made between it, on the one hand, and the Cheribon, on the other. As a result of this crossing, several hybrids were obtained which produce the maximum amount of sugar and are at the same time resistant to the disease. As sugar cane is propagated by using its vegetative parts, that is parts of the stem, these qualities can be readily preserved. Notwithstanding these favorable results, however, our experience with sugar cane has proved that its "immunity" is not permanent, but diminishes in the course of cultivation, and the same is true in the case of the two varieties of coffee mentioned, the disappearance of immunity in

these being relatively rapid. No guarantee of future disease resistance has been found in either the hybrids or in the wild species.

Not only do closely related species show a difference in susceptibility to disease, but varieties and races of the same species behave differently in this respect. An example of this is *Triticum dicoccum*, one variety of which, as already stated, is resistant to rust and the other non-resistant. Additional examples are *T. vulgare*, a few varieties of which are resistant; certain varieties of potatoes with reference to *Phytophthora infestans*; *Pinus sylvestris* with reference to *Lophodermium pinastri*; and other cultivated plants. This difference in disease-resistance between races of the same species is of far greater importance than the difference between two species, because generally there is greater similarity between the cultural value of the two races.

The occurrence of healthy plants among diseased ones is not absolute proof of the resistance of such plants, and therefore to make sure of the immunity of any special strain careful experiments are necessary. It is not enough to raise a number of plants of an apparently resistant strain in a certain place. The question of resistance should be investigated from the beginning on the broadest basis. One of the principal things necessary is to expose the resistant plants to the fungus causing the disease to which they appear to be resistant. In the case of fungi which live in the soil, such, for instance, as the fungus causing stinking smut, the first requisite is to determine whether they are present and, if not present, to introduce them, while in the case of fungi spread by the wind, such as those causing rust and mildew, the infection should be induced either naturally or artificially.

The presence of the fungus, however, is only one factor in the experiment. The second factor is the disposition of the host plant, that is, its internal qualities, which makes infection possible. The third factor is the coincidence of the infection period with the susceptible condition of the host. When all of these factors are present the possibility of infection is certain, and only under such circumstances will the results be reliable.

Fluctuation in the prevalence of fungous plant diseases is due to the presence or absence of proper conditions for the development of the fungi causing them. For instance, loose smut appears to a very serious extent in certain summers, and naturally it would be expected to be still more prevalent the succeeding summer. The fact is, however, that although spores in sufficient quantity to infect all the flowers in the field were scattered, the disease may be much less serious, the reason being that the plant was not in the proper stage a sufficient length of time to receive the infection, or in other words the weather conditions caused too rapid withering of the flowers to permit infection.

The effect of different conditions on the relation of host and parasite makes it necessary that investigations to determine the resistance of strains shall be carried on not only for a number of years, but also in different localities. Even under such circumstances the outcome may be uncertain. In many cases immune forms when cultivated prove to be only partly immune.

The best opportunity for finding immune strains is afforded by diseases which are of regular occurrence. In such cases it is possible to find with a degree of certainty forms which are immune in a certain locality, but while such experiments may give results of practical value, the

problem of immunity can not be solved in this way.

The third way to obtain immune forms is to select resistant individuals and from them breed pure strains. In the case of many diseases, although certainly not in all, healthy individual plants are found in the diseased plots, and the breeding of immune strains from these individuals would seem to be very simple, but experience has taught the contrary. All the factors pointed out in connection with the selection of immune forms must be reckoned with, but in a still greater degree. So long as the appearance of the disease is the only criterion by which to determine the susceptibility of the plants to disease the experimenter is exposed to all kinds of unknown influences.

Several attempts to breed kinds of wheat immune to stinking smut have been made without any real results. The question of producing such kinds is of great importance, especially for the United States. In the large wheat areas of Idaho and eastern Washington, for instance, stinking smut is very serious, not infrequently causing a loss of twenty-five per cent. of the crop. Inspection of seed in that state discloses the fact that a large part of it is covered with the smut spores, and treatment of the seed with copper sulphate is said to be useless because the soil is so badly infected. In many European countries, however, smut has been completely controlled.

In the case of smut the possibility of infection, as far as the fungus is concerned, is very great. As infected plants are in general not very productive on account of the seed being destroyed by the fungus, it might be supposed that smut-resistant plants would propagate well and that the strains would become immune. This, however, is not the case, and it shows that the

breeding of smutless wheat by selection of healthy individuals has little chance of success, a fact which has been proved by experiments already made. That this is an impossibility, however, can hardly be stated definitely, but success could be obtained, if at all, only after tremendous amount of labor in breeding and trying hundreds of forms or by fortunate accident.

It will be remembered that Orton by this method of breeding succeeded in obtaining varieties of cotton and watermelon resistant to *Fusarium* wilt. As the original resistant individuals found in the field gave too small yields, he crossed them with prolific varieties and in this way combined the disease resistance of the one parent with the productivity of the other. A similar thing was done by Bolley with flax and by L. R. Jones with cabbage, both of whom bred wilt-resistant varieties by selection. In the case of wheat, it is the opinion of the writer that there would be better chance of breeding smut-resistant varieties if strains rather than individual plants were selected and crossed with productive varieties. Orton very successfully selected a certain variety of cowpea resistant to wilt disease and root knot, that is, the iron cowpea grown in South Carolina, and crossed it with a more desirable variety. By this means also, that is by selecting certain varieties, some of the *Phytophthora*-resistant varieties of potatoes were obtained, and probably also the square head wheat which shows immunity to *Puccinia tritici*.

Next to field experiments, those in the laboratory might aid in the discovery of resistant varieties of cultivated plants. Such experiments have advantages over those in the field and are practical in case of diseases caused by parasites that may be grown artificially in pure cultures.

The greatest advantage of the laboratory experiments is that in them the experimental plants may be infected at any time and under any conditions. The plants may be kept dry or wet and under different temperatures, they may be fed in different ways, and the factors of growth may be influenced within wide limits. Under such conditions the optimum of infection may be determined for different varieties.

The results of laboratory experiments frequently differ greatly from those of field experiments. For instance, in Wawelow's field experiments *Triticum durum*, *T. polonicum* and *T. turgidum* were resistant to *Erysiphe graminis*, but in his greenhouse experiments they became infected with this disease. Reed's experience in this respect was similar to that of Wawelow. It is the opinion of the writer that the host plants were strongly influenced by circumstances, but Wawelow attributes the different results to favorable conditions in the greenhouse for the development of large quantities of conidia.

Such unbalancing of the host is not infrequent and in the natural environment is due to extreme weather conditions. Some species of *Ribes* are known to be immune to the æcidium of the pine blister rust (*Peridermium strobi*), but these species may be infected and form æcidia under a bell jar. In the field the leaves are infected, this being shown by the development of slight yellow patches, but the æcidia never appear. The same is true in the case of some varieties of wheat with regard to *Puccinia*, according to Fraser, on account of the thickness of the cuticle. This partial immunity is satisfactory for practical purposes, and while partially immune plants suffer in a small degree through reduction of the assimilating surface, they do not increase the danger

of spreading the rust, as they form no new sources of infection.

Although some very profitable results have been obtained, as already shown, from the immunity methods discussed, the problem of immunity should be solved in a different way. Immunity must not be regarded as the only definite point to be studied. In the case of every special disease efforts should be made to determine the causes of resistance. That immunity from different diseases is due to different causes is clear and the factors which determine this must now be sought. ✓

The cause of immunity of wheat and barley from loose smut is among the simplest. From the investigations of Hecke and Brefeld it is known that the smut spores are carried by the wind to the stigma and that there they germinate and find their way to the ovule through the pollen tubes. As is generally known, there are varieties of wheat which have closed flowers, which means that fertilization takes place within the glumes. In such cases the smut spores can not reach the stigmas at the proper time, and therefore infection can not take place. In this case, therefore, by investigating the question of flowering the problem of resistance can be solved without artificial infection. Many of the intermediate stages which exist between immune and susceptible races may be detected by close observation. In like manner several races of rye show different degrees of susceptibility to ergot (*Claviceps purpurea*), the resistance being least in those having a long flowering period.

The channel from the calyx to the carpels is open in many varieties of pears. Such varieties are susceptible to infection by *Fusarium putrefaciens*, as Osterwalder has shown. The varieties without the open

channel are protected against this means of infection.

The habitus of a plant may influence its disease resistance. An instance of this is the potato with reference to the late blight (*Phytophthora infestans*). Infection of the potato vine with this disease is caused by the conidia being carried to the leaves by the wind. The conidia remain on the leaves until a drop of water causes them to liberate their zoospores. These swim around in the water for some time, then drop their cilia, germinate, and send a hypha into a stoma. Passing through a potato field shortly after a heavy rain, it will be observed that the leaves of some sorts dry within half an hour, while others remain wet for several hours. Generally the quick-drying varieties are less susceptible to the disease than the slow-drying varieties. Slow drying is the result of the plant's habit of growth, which hinders the evaporation of the rain drops. Such plants have flat leaves. Small, hairy leaves, as well as an airy, open growth of the whole plant, facilitate drying. It is possible that the arrangement of the stomata also may exert an influence on the attack of the fungus.

In the case of the grape leaf the arrangement of the stomata is of great importance. For a long time it was not known why spraying with Bordeaux mixture did not, in all cases, prevent the attack of *Pero-nospora*. Finally, however, Ruhland and Müller-Thurgau explained this by showing that in the grape leaf the stomata are formed only on the under surface. Spraying of the grape, therefore, can be effective only when the spray mixture reaches the under surface of the leaves, and this fact must be borne in mind when dealing with fungi which enter the leaf through the stomata. A similar thing was observed by the writer's assistant, Dr.

Pietsch, whose investigations have not yet been published. He found that the resistance of some Remontant carnations is due to the form of the stomata, which makes it impossible for the hyphae to penetrate them. In some cases, however, the hyphae can not produce infection even though they penetrate the stomata. In the case of cereals immunity from rust is independent of the stomata. ✓

In cruciferous plants the water pores are the avenues of entrance for many bacterial diseases. The relation between their form and disease resistance, however, has not yet been established.

As may be seen in the case of the potato, the lenticels as well as the stomata may influence immunity. The scab fungus (*Oospora scabies*) after penetrating into the outer layers of the potato establishes itself in the lenticels and causes the surrounding tissues to produce an abnormal corky growth. Bacteria also may enter the lenticels, especially when on account of moist conditions the tissues are forming callus. This callus, however, does not form a sufficient protection, and softened tissue and even decaying spots result.

The lenticels are developed very differently in different varieties of potatoes, and it is therefore important that the relations between them and resistance to scab and bacterial rot be investigated.

The condition of the cuticle may influence infection, as shown by the behavior of cereal seedlings in resisting smut diseases. Such influence, however, is possible only in the very early stages of the seedlings' growth, that is before the tissues have attained full development. Since the germination tubes of smut are able to dissolve cellulose, there must be stored substances which cause resistance, and in this connection silicic acid is probably the first to suggest itself. Indeed the quantity of

this substance is different in seedlings of different kinds. Sorauer found resistance of different carnations to be due to thickness of the cuticle. It might be caused also by the wax layer, which is present in *Graminea*, carnations, and other plants.

✓ In his experience the writer found that the wax layer influences the attack of *Coniothyrium* on raspberries. In a large horticultural establishment varieties which were covered by a thick blue wax layer were free from this disease, while other varieties were completely killed. The wax layer may exert its influence in different ways, that is it may prevent direct penetration by the hyphae or it may act indirectly by causing the moisture to run off the plant. This was observed by the writer in making sprayings with Bordeaux mixture. In the case of plants covered with the wax layer the mixture ran off quickly and left no moisture. Conflicting results have been obtained from observations of *Glæosporium venetum* on raspberries on the fruit farm of the University of Minnesota. There is no difference between raspberries with wax and without wax. *Glæosporium venetum*, however, has very sticky conidia and is held by the wax layer, while *Coniothyrium* spores are washed away.

The hairs on the surface also play a part in this connection. Their unfavorable influence in the case of potato late blight has already been mentioned. A very interesting case of hair-like structures is found in the pea family. In some varieties the seeds are imbedded in a woolly outgrowth of the inner epidermis of the pod. Frequently when pods are infected with *Ascochyta pisi* the fungus penetrates into the interior. In varieties without these hairs the seeds are infected only when they are directly in contact with an infected spot of the pod. But when the interior is

covered with the woolly outgrowth the fungus grows as in a culture medium and infects every seed.

The cork, which is without doubt a protecting tissue, is a definite kind of epidermis. The writer has never seen branches of cork elms attacked by fungi, but the common elm is subject to the attacks of several species. In the case of the potato the cork layer has the greatest significance.

The causes of the protecting action of the cork, however, may be different. Certain fungi are able to penetrate this cork layer, such as *Phytophthora*, and probably *Fusarium* and *Spondylocadium*. But the last-named fungus is able to penetrate only the very outermost layers of the potato, where it forms mycelium and sclerotia normally. Whenever it grows into the tissues below it must use the channels already opened by other fungi which may happen to be present. Thick cork layers seem to be impenetrable for *Phytophthora* and *Fusarium*. The questions involved are very difficult to solve, because it is hardly possible to judge whether a cork layer is intact or not.

As small wounds occur very generally, the rapidity with which wound cork is formed is possibly of more importance than the absolute thickness of the cork layer. In the course of work with black leg of the potato the writer was able to study this question. It is easy to cure a bacterial infection artificially. The potato is able to close a wound within a short time by the formation of cork. When the growth of bacteria is diminished by low temperature or drought the potato closes wounds more rapidly than the bacteria can penetrate. The ability to form wound cork varies in different varieties of potatoes. Some varieties begin cork formation within six hours after the wound is

inflicted, while in other varieties it is not begun for forty-eight hours or more. From this it is clear that the former may withstand infection better than the latter. By means of these experiments the relation between the structure of the plant and its bacterial resistance has been established beyond doubt. A similar relation, however, does not exist in the case of fungous diseases, as the fungi may penetrate the newly formed cork.

All the instances cited illustrate the influence of mechanical means of protection. But the plant also often escapes disease by means of rapid growth. A microscopic examination of seedlings attacked by smut shows that a number of seedlings may be infected, and yet only a few of the plants will show the disease, proving that the infection has been suppressed in many cases. In this connection attention is called to the fact that in the case of both stinking and loose smut the infection originates in the seed. The fungus mycelium grows in the seedling, but by rapid growth the latter may outstrip the fungus, which remains in the base of the plant and is harmless.

There are still other factors in plants which may influence resistance but which are not perceptible through the microscope. They may be found by physical or chemical research because they are based on the difference of contents. Probably these factors are of far greater importance than those already discussed. But till now these questions are far from being treated in an adequate manner. The foremost reason for this may be that here we have to deal with chemical substances such as albumens, tannins, etc., and there are few botanists who possess the necessary chemical knowledge to undertake such experiments. A bridge, therefore, must be built between botanists and chemists, and the latter's interest in this question awakened.

One of the best investigations made in this direction up to this time is that of Münch on the immunity and susceptibility of trees. He has shown that susceptibility of woody plants to fungous diseases depends on the quantity of water and consequently on the quantity of air in the wood. This is in accordance with the writer's experiments with *Rhizoctonia* and *Fusarium* which have shown that these fungi also have a high air requirement. In the United States, with its large areas of irrigated land, this fact is of great importance. It is possible that the influence of both of these fungi may be diminished by thorough regulation of water conditions.

A glance at sugars and acids shows that these substances also exert an influence in disease resistance. The presence of benzoic acid in *Vaccinium vitisidæa* is supposed to be the cause of its resistance to fungous diseases. In the same way the tannins have a relation to resistance. This was shown by Behrens in his work on fruit decay and confirmed by Cook and Taubenhaus. On the other hand, sugar favors the growth of fungi, as is shown clearly in the case of apples and pears. Henneberg even claims immunity for some varieties of potato from certain diseases on account of their high sugar content, but this has not been established beyond doubt.

Finally the enzymes exert a definite influence on immunity, the oxydases taking the lead. These ferments work directly or indirectly by producing resistant chemical substances.

This paper, it is believed, gives sufficient idea as to how, in the opinion of the writer, the problem of disease resistance should be dealt with in the future. The present methods should by no means be abandoned, for practical experience and happy accidents may help a great deal, but in addition to carrying out these methods an ef-

fort must be made to establish scientific fundamentals for new investigations. Efforts must be made to find the causes of immunity, and after solving this question to determine without infection the disease-resistant qualities in different varieties and individuals in order to be able to establish the desired resistance and at the same time eliminate undesirable qualities. It is only by working along this line that the breeding of disease-resistant varieties on a scientific basis can be accomplished and results which lie within the limits of possibility obtained.

KAISERLICHE BIOLOGISCHE ANSTALT,
BERLIN-DAHLEM

THE CAVERN OF THE THREE BROTHERS
(ARIEGE)

FOR the third time in less than three years it has been the good fortune of Count Begouen of Toulouse to announce the discovery of important works of art left by paleolithic man on the walls and floor of Pyrenean caverns. His two previous discoveries were noted at the time in the columns of SCIENCE.¹

Quaternary art objects may be classed under two heads: the portable and the stationary. The portable class includes in part carved tools, weapons and ceremonial objects, such as poniards, spear throwers, bâtons, etc. It also includes engraved pebbles as well as carved fragments of stone, bone, ivory and the horn of stag and reindeer; in fact, almost anything that could be seized upon to satisfy the exuberant demands of the cave man's artistic impulse.

Stationary art embellishes the walls and ceilings of caverns and rock shelters. In rare instances the fine clay of the cavern floor was utilized for sketching and modeling purposes. The scientific world has been more or less familiar with the portable class of troglodyte art for more than half a century. Our acquaintance with the stationary art is of more re-

cent date. The first discovery of this kind was made by Sautuola in 1879 at the cavern of Altamira in northern Spain. The scientific world, however, did not grasp the real significance of Sautuola's discovery until, after the lapse of nearly twenty years, similar finds had been made in France.

All three of Count Begouen's discoveries have to do principally with cave art of the stationary kind. In July, 1912, near his country estate of "Les Espas," which is only a short distance from Saint-Girons (Ariège), he found a series of subterranean galleries and connecting corridors opening out of an underground stream bed. On the walls of one of the corridors were several engravings of the horse, reindeer, mammoth, etc. Five days later it was the privilege of the writer to see this prehistoric gallery, called Tuc d'Audoubert, in company with Count Begouen and his three sons.

In October of the same year Count Begouen and his sons succeeded in gaining entrance to an additional gallery of the series, but not until after they had broken down two stalagmite pillars that blocked the narrow passage way. What they found there has already been described. The most notable objects were two figures of the bison modeled in the clay of the cavern floor. They owed their preservation to the accidental sealing up of the gallery ages ago by the stalagmite pillars. In view of their excellence, it is probable that they are not unique examples; that perhaps other similar figures less fortunately situated have been destroyed because the artist did not know how to temper and fire his product.

The need of something less difficult to manipulate than stone, bone, ivory and horn must have been ever present in the experience of the troglodyte artist; it is not strange therefore that he should have finally hit upon clay. This illustrates how near an individual or a race may come to some great discovery and yet fall short of it. Thus was the discovery of the ceramic art left to the later more practical, if less artistic, neolithic races.

The latest discovery of Count Begouen and

¹ N. S., XXXVI, pp. 269 and 796, 1912.

his sons, announced recently in a note read at the French Institute, the substance of which is contained in a letter just received from him, was made only a few days before the declaration of war last August. In fact, it was on July 20, 1914, exactly two years after the discovery of Tuc d'Audoubert, that he and his three sons descended by an opening until then unknown into a superb cavern, which in their honor he has named *Caverne des Trois Frères*. It is about half way between Tuc d'Audoubert and the cave of Anlène, in other words about a quarter of a mile from each. Count Begouen believes that the three caverns are connected by corridors; proofs of a connection between two are already in hand.

The exploration was not only difficult, but also dangerous (there are galleries into which he has not yet been able to penetrate), but one is well paid for the effort because of the beauty and elevation of the ceilings as well as "the numerous prehistoric remains encountered there." On the floor were many bones, flint implements and objects bearing man's handiwork.

The results of their first visits were of such a nature as to foretell an abundant harvest when the work shall have been resumed. Upon a bone fragment there was an excellent engraving of a fish. But the chief display of art was on the walls, especially of the terminal gallery, where more than two hundred admirably engraved figures of animals are to be seen. The following species have already been identified: Mammoth, rhinoceros (the first found in the caverns of the Pyrenees), bear, lion, wolf, deer, reindeer, wild goat, horse, bison, chamois, eel and bird. There are also anthropomorphic figures including a curious female type drawn in black; it seems to be walking almost on all fours with the head surmounted by a reindeer horn. It might represent a human figure wearing a mask, or perhaps a figure with mixed attributes; if the latter, then we have a new note in paleolithic art, for until now that art has revealed no representations of mythologic creatures.

Most of the mural art in the *Caverne des*

Trois Frères is admirably done; a small panel with reindeer at rest evidently enjoying themselves is "like a page from an album." From the viewpoint of the engravings this cavern is "certainly the richest and the most beautiful thus far known." In addition to the animal and anthropomorphic figures, Count Begouen noted lines, spots of red or black, and red claviform signs, presumably representing clubs.

War was declared before excavations could be begun. With two of the "trois frères" at the front since then and the youngest having recently joined them there, it can readily be understood why Count Begouen does not wish to return to the cavern so aptly named until he can do so accompanied by his three boys after the war is over. Let us hope that he may have to wait neither long nor in vain.

GEORGE GRANT MACCUDRY

YALE UNIVERSITY,
NEW HAVEN, CONN.

SOME EARTHQUAKE PHENOMENA NOTED IN PANAMA

In October, 1913, the writer was asked by President Porras of Panama to undertake some investigation into the causes of the earthquakes which, during that month, were felt almost daily in the Azuero peninsula which forms the south central part of the republic.

In the course of this investigation two well-recognized geological principles took on a new and impressive significance for the writer, and a vividness that he had never before been able to clothe them with. These principles are the relation of faulting and fracture to earthquakes, and the elasticity of the earth as expressed in earth-waves.

Simultaneously with the first and heaviest shock the cable line from Panama up the west coast to California broke at a point where it passes over the submarine escarpment from the continental shelf at about 60 fathoms to the ocean depths at from 700 to 1,000 fathoms. The distance on the chart from the 60-fathom sounding to the 784-fathom sounding is less than two miles. It is not known, however, whether the slope between these two points is

uniform or locally abrupt. Not only did the cable break, but the repair boat reported that half a mile of it had been buried in debris on the bottom and had to be abandoned and a new piece spliced in.

It is said that the cable was broken in almost the same place by an earthquake between the years 1882 and 1883.

To the writer the only adequate explanation of the breaking of the cable and the burying of half a mile of it is that movement occurred along an old fault escarpment, or fault zone, which marks the boundary between the continental shelf and the deep ocean basin, and that this movement was great enough to cause the earthquake, resulting in a submarine landslide. It is not known whether the fault displacement broke the cable or whether the submarine landslide caused by the jar of the faulting broke it; of course the jar of the fault movement was the earthquake.

Nearly all of the later shocks felt were accompanied by peculiar underground sounds which, at times, seemed to begin to the eastward of the observer and to die away in 5 or 10 seconds to the westward of him. The sound was not unlike the dull boom made by the fracture of ice on large lakes, due to shrinkage, when the weather has suddenly become extremely cold. The noise of these ice fractures may begin far to the right of an observer and die away in the distance, in a few seconds, to the left of him. After listening, several times, to the underground sounds that accompanied shocks, the writer became convinced that they were due to the formation of small shears or strain-relieving cracks in the rocks, formed perhaps considerably below the surface. A search for such cracks was unsuccessful, due either to the sparsity of rock exposures or to the fact that cracks might not be distinguishable from ordinary jointing, or that they might be parallel, or nearly parallel, to the surface and might not outcrop in the vicinity at all. It is thought that the rock strains would be relieved by many very small fractures along a strained zone rather than by one large break, and the differential movement along each small fracture

might be extremely small, possibly measurable say in tenths of an inch.

The breaking of the cable and the burying of a part of it, together with the underground sounds heard several times, as far as the writer can see admit of no other adequate explanation than that herein ascribed to them.

The other geological principle connected with these earthquakes was that of the elasticity of the earth's crust. The writer was on the top of a steep conical mountain peak which stood about 2,000 feet above the surrounding country, when a heavy quake came, causing the mountain to behave like a stiff jelly. One felt as though the mountain were swaying through an arc of several inches. Making ample deductions for the tendency of the senses to exaggerate such an unusual phenomena, it is thought that the swaying motion in a horizontal plane was actually about three quarters of an inch. It was one of the most impressive demonstrations of the elasticity of solid rock, of the somewhat jelly-like motion that can be imparted to a "rock-ribbed" mountain, that one could well imagine. With the motion a dull, heavy underground rending sound began on the northeasterly to northerly side of the mountain and died away in the distance on the other side, being audible for say 20 to 25 seconds.

These underground sounds had a most terrifying effect on the inhabitants, who believed they were about to be overwhelmed by some volcanic catastrophe. The investigation was very successful in assuring them that these dreaded sounds were quite harmless and were not due to any subterranean fires, and that the near-by mountains were not going to turn into volcanoes and overwhelm them as they feared. In spite of this soothing information, however, a few of the natives were unjust enough to criticize the writer for not stopping the quakes as quickly as they wished. Such is "man's inhumanity to man."

DONALD F. MACDONALD

U. S. GEOLOGICAL SURVEY

THE THOMAS SAY FOUNDATION

AN organization, with the above name, was formed under the auspices of the Entomolog-

ical Society of America at its Philadelphia meeting. Its purpose is to honor the memory of the father of American entomology, Thomas Say, by the publication of a series of volumes on systematic entomology. These volumes are to be of a monographic or bibliographic character and to deal only with the insects of North America. It is hoped that a series of volumes similar in appearance and of the same high standard as the volumes of the John Ray Society of England can be issued. To this end a temporary committee consisting of J. M. Aldrich and Nathan Banks, U. S. Bureau of Entomology, E. P. Van Duzee, University of California, Morgan Hebard, Academy of Natural Sciences of Philadelphia, treasurer, and Alex. D. MacGillivray, University of Illinois, editor, was appointed to solicit funds, and when these are sufficient, to issue such works as they may deem worthy of publication. The most difficult problem confronting the committee is the securing of a fund sufficient for publication. It is hoped that an endowment fund, the income from which will be sufficient for the issuance of about two volumes per year, will eventually be available. Until such a time, however, an attempt will be made to obtain subscriptions for the issuance of volumes.

AWARDS OF THE FRANKLIN MEDAL

THE Franklin medal, the highest recognition in the gift of The Franklin Institute of the state of Pennsylvania, has recently been awarded to Ilseke Kamerlingh Onnes and to Thomas Alva Edison. The awards were made on the recommendation of the institute's committee on science and the arts, that to Onnes being in recognition of his "long-continued and indefatigable labors in low-temperature research which has enriched physical science, not only with a great number of new methods and ingenious devices, but also with achievements and discoveries of the first magnitude" and that to Edison in recognition of "the value of numerous basic inventions and discoveries forming the foundation of world-wide industries, signally contributing to the well-being, comfort and pleasure of the human race."

The Franklin Medal Fund, from which this medal is awarded, was founded on January 1, 1914, by Samuel Insull. Awards of the medal are to be made annually to those workers in physical science or technology, without regard to country, whose efforts, in the opinion of the institute, have done most to advance a knowledge of physical science or its applications. The present awards are the first to be made.

The medal awarded to Professor Onnes was received on behalf by His Excellency, Chevalier van Rappard, minister from the Royal Netherlands government, at the stated meeting of the institute on the evening of Wednesday, May 19, and at this meeting Mr. Edison was the guest of the institute and received his award in person. Following the presentations, an address entitled "Electricity and Modern Industrial Growth" was delivered by Mr. Insull.

SCIENTIFIC NOTES AND NEWS

DR. FRANK J. GOODNOW was installed as president of the Johns Hopkins University on May 20. After he had delivered his inaugural address on "Modern Educational Ideals," he conferred degrees on twelve distinguished scholars and scientific men who were presented by Dr. William H. Welch. The scientific men on whom the degree of doctor of laws was conferred are as follows: John Mason Clarke, state geologist and paleontologist of New York; John Dewey, professor of philosophy, Columbia University; Simon Flexner, director of the laboratories of the Rockefeller Institute for Medical Research; George W. Goethals, major general of the United States Army, chief engineer of the Panama Canal; Thomas Hunt Morgan, professor of experimental zoology, Columbia University; Michael I. Pupin, professor of electro-mechanics, Columbia University; Robert Simpson Woodward, president of the Carnegie Institution.

At its annual meeting held on May 12, the American Academy of Arts and Sciences, acting upon the recommendation of the Rumford Committee, voted: "That the Rumford Premium be awarded by the Academy to Charles Greeley Abbott for his researches on Solar Radiation." The committee has appropriated

\$140 to Professor Joel Stebbins, of the University of Illinois, in aid of his research with his improved photo-electric cell photometer upon variable stars.

THE first award of the Ackermann-Teubner memorial prize in mathematics has been made to Professor Felix Klein.

THE British Institution of Civil Engineers has awarded its Telford gold medal to Mr. A. L. Bell (Rosyth); Telford premiums to Mr. C. W. Anderson (Chakradharpur, India), Sir Thomas Mason (Glasgow), Dr. H. F. Parshall (London), and Mr. H. E. Yerbury (Sheffield), and the Crampton prize to Mr. F. D. Evans (Kuala Lumpur).

PROFESSOR SYDNEY J. HICKSON has been elected president of the Manchester Literary and Philosophical Society for the ensuing year (1915-16).

THE corporation and faculty of Brown University gave on May 24 a complimentary dinner to Professor Nathaniel F. Davis and Professor William C. Poland, heads of the departments of mathematics and art, who next month retire on pension, after over forty years of service.

THE Cordilleran Section of the Geological Society of America has elected Professor C. F. Tolman, Jr., of Leland Stanford Jr. University, chairman in place of Dr. H. Foster Bain, resigned, and Mr. Joseph A. Taff, 781 Flood Building, San Francisco, secretary, in place of Professor G. A. Louderback, resigned.

ON the staff of associate editors of the *Transactions of the American Mathematical Society* Professors A. B. Coble and W. A. Hurwitz have succeeded Professors J. I. Hutchinson and Max Mason, who have served since 1902 and 1911, respectively.

H. H. M. BOWMAN, of the University of Pennsylvania, has been appointed botanical research investigator at the laboratory of the Carnegie Institution on the Dry Tortugas. He will sail from New York for the West Indies on May 29.

UNDER the auspices of the American Museum of Natural History, Dr. Robert H. Lowie, of the department of anthropology, will leave early in June in order to undertake in-

vestigations among the Hopi of Arizona and the Moapa Paiute of southern Nevada.

DR. F. L. STEVENS, professor of plant pathology in the University of Pennsylvania, will be engaged during the summer in a biological survey of Porto Rico, collecting and studying tropical plant diseases and fungi. He will sail June 5 accompanied by Mrs. Stevens and by several students.

FROM the *Zeitschrift für Angewandte Entomologie* we learn that Dr. Georg Escherich, Forstrat in Isen, was badly wounded by shattering of the tibia near Markkirch; Dr. W. Herold, of Greifswald, is in a hospital in Berlin with five wounds; Dr. K. H. C. Jordan, of Neustadt, is in a hospital at Lambrecht; Professor Dr. A. Thienemann, of Münster, has been injured by a shell splinter in the upper thigh and lies wounded at Bonn.

THE Paris Academy of Sciences, after considering a report presented in secret committee by M. Adolphe Carnot, has passed a resolution removing from its membership four German scientific men, including Dr. Wilhelm Waldeyer, professor of anatomy, and Dr. Ernst Fischer, professor of chemistry, in the University of Berlin.

It is stated in *Nature* that Mr. J. E. Oulum retires from the post of superintendent of the Valencia Observatory, Cahirciveen, Co. Kerry, Ireland, and that Mr. H. G. Dines has been appointed to succeed him, as from May 1. Mr. A. H. R. Goldie has been promoted senior professional assistant to Mr. Dines at the observatory at Ekdalemuir.

PROFESSOR WATERBURY, of the University of Arizona, gave on May 12 an illustrated lecture on "Arizona and the Southwest," before the Civil Engineering Society of the University of Illinois. The pictures shown portrayed the development of the reclamation work in Arizona.

THE final meeting of the year of the Columbia Sigma Xi, at which the Columbia Chapter of the Phi Beta Kappa was the special guest, was held on May 19. Dr. W. J. Gies spoke on "Diseases of the Teeth and Bones, their Causes and Prevention, with Some Demonstrations."

At the second annual meeting of the Kentucky Academy of Sciences, Professor Dayton C. Miller, of the Case School of Applied Science, gave a lecture on "The Science of Musical Sound," and was elected an honorary member of the academy. Professor A. M. Miller, of the department of geology, of the Kentucky State University, has been elected president of the Kentucky Academy of Science.

DR. FRANCIS G. BENEDICT addressed the students at Vassar College on Monday afternoon, May 10, on "Investigations in the Nutrition Laboratory of the Carnegie Institution of Washington." In the evening he addressed the advanced students in chemistry and physics and the instructors on "Women as Research Assistants."

AMONG recent scientific lectures before the faculty and students of Oberlin College have been the following: "Business and Kultur," by Professor Arthur G. Webster, of Clark University; "Some Physical Characteristics of the Vowels," by Dayton C. Miller, of Case School of Applied Science; "Recent Evidences as to the Nature of Molecules and Atoms," by Dr. Robert A. Millikan, of the University of Chicago. Dr. Millikan also made an address on "The Significance of Modern Scholarship," this being before the Society of Phi Beta Kappa.

At the University of Cambridge the Linaere lecture was delivered by Professor E. H. Starling, on May 6, on "The Governor Mechanism of the Heart." The Rede lecture was delivered by Dr. Norman Moore, on the same day, on "St. Bartholomew's Hospital in Peace and War."

We learn from *Nature* that a monument to the late Professor J. H. van't Hoff was unveiled at Rotterdam on April 17. It consists of a bronze statue, double life-size, in sitting position, and has been placed in front of the school at which Professor van't Hoff was educated. The monument is about 80 ft. high, and the statue itself is flanked by female figures representing "Imagination" and "Reason." On the front of the base is the following inscription:

VAN'T HOFF,
1852-1911.

Physicam chemiae adiunxit.

JOSEPH JOHNSTON HARDY, professor of mathematics and astronomy at Lafayette College, died at his home on May 2. He was born in New Castle, England, in 1844, and came to this country in 1846. He was graduated from Lafayette College in 1870 and immediately became a member of the teaching staff. He is survived by two daughters and a son, James Graham Hardy, now professor of mathematics at Williams College.

WILLIAM JAMES SELL, F.R.S., university lecturer and senior demonstrator in chemistry at the University of Cambridge, has died at the age of sixty-eight years.

ERASMUS DARWIN, the only son of Mr. and Mrs. Horace Darwin, of Cambridge, a grandson of Charles Darwin and of the first Lord Farrer, was killed on April 24 in Flanders. For a time he carried out work in the test-room of the Cambridge Scientific Instrument Company and later became engaged in administrative work.

THE April number of the *Review of Applied Entomology* states that Duncan H. Gotch, entomological assistant in the Imperial Bureau of Entomology, London, was killed in action at Nieuve Chapelle on March 11, while acting as second Lieutenant in the Worcestershire regiment.

MR. SANDERSON SMITH, malacologist, of Port Richmond, Staten Island, N. Y., died on March 28, aged 83 years. He was born in London on May 14, 1832. He studied in the School of Mines, in London. From 1860 to 1870 he published a number of papers in the *Annals of Lyceum of Natural History of New York*, on the Mollusca of Long Island, Staten Island and adjacent islands. From 1875 to 1887 he was one of the volunteer assistants engaged in the various dredging expeditions carried on by the U. S. Fish Commission off our eastern coast, including the deep sea work, and was of great service in that work. Later in life he made extensive collections of maps, charts and engravings. He also compiled, for

the Fish Commission Reports, lists of all the dredging stations occupied by the vessels of the United States and foreign countries, with all the physical data obtained, thus forming a valuable oceanographic work.

A TELEGRAM received at the Harvard College Observatory from Professor E. B. Frost, director of Yerkes Observatory, Williams Bay, Wisconsin, states that two companion bodies have been found by Professor Barnard near Mellish's Comet. One of these was conspicuous, and had a distance of $28''$ and a position angle of 285° , on May 12, at $19^h 36^m$. The other was faint, and occupied an intermediate position in the same line. A cablegram received at the observatory from Professor Elis Strömgren, director of the University Observatory, Copenhagen, Denmark, states that Delavan's Comet, the discovery of which was recently announced, proves to be Tempel's periodic comet. Ephemerides of this comet, by Strömgren and Braae, are published in *Astronomische Nachrichten*, No. 4792.

DR. WINFORD H. SMITH, superintendent of the Johns Hopkins Hospital, has announced a gift of \$16,500, to be paid in three yearly installments, from Mr. John D. Rockefeller, Jr., to be used in a special social hygiene department at the hospital, which is to be established next September. The work of the new clinic will be in charge of a committee consisting of Dr. George H. Walker, chairman, Dr. Theodore C. Janeway and Dr. Winford H. Smith. Dr. Albert Keiden, a graduate of the Johns Hopkins Medical School, will be the physician in charge of the new dispensary. He will have four assistants.

ON account of the unfavorable state of the finances of the country, due mostly to the European war, the Peruvian government has ordered the closing of the Museum of the National History and Archeology at Lima. This action is much to be regretted, for the archeological part of the museum was, in many respects, the most important in South America.

THE annual meeting of the German Surgical Association was supposedly postponed on account of the war, but we learn from the

Journal of the American Medical Association that the surgeon-general of the army sent out a summons for the meeting to be held at Brussels. Hundreds of surgeons attended the meeting, which commenced at Brussels on April 7. All the sessions were devoted to military surgery and a number of new points learned from practical experience were brought out. Drs. Garré, Körte, Payr and Bier delivered the leading addresses.

THE fortieth annual meeting of the American Academy of Medicine will be held in San Francisco, June 25 to 28, under the presidency of Dr. John L. Heffron, of Syracuse, N. Y. The sessions will be held in the Auditorium Hall of the Panama-Pacific Exposition. The program will include addresses by the president, Dr. Woods Hutchinson, and Dr. David Starr Jordan. Dr. Jordan's address will be on the Relation of Medicine to the Peace Movement.

THE glass used in this country for the manufacture of lenses is practically all imported except in the case of some of the smaller and cheaper lenses. For several years past, the Bureau of Standards, of the Department of Commerce, has been endeavoring to persuade the glass manufacturers of the United States to take up the manufacture of this material, but they have been unable to do so, partly because of the limited quantity used as compared with other glass, but largely on account of the varying composition required and the difficulty of annealing the glass, as good optical glass must be entirely free from strain. With a view to working out some of the underlying problems sufficiently to enable manufacturers to start in this matter, the Bureau secured two years ago an expert interested in the composition and testing of optical systems, and a little later secured another man skilled in the working of glass to the definite forms required by the theory. These steps were taken first, partly because it is exceedingly difficult to find men having these qualifications, put principally because as the work of experimental glass making progresses, the glass must be put in the form of lenses and prisms to test; in other words, the

Bureau had to be in a position to examine the product as it was made experimentally. In July, 1914, a practical glassmaker was added to the force of the bureau. He is a college graduate of scientific training but skilled in the manipulation of furnaces, and is the sort of a man to make progress at the present stage of the work. Small furnaces were built and melts of a few pounds of ordinary glass were made in order to become more familiar with the technical side. A larger furnace has just been completed which will handle melts of 25 to 50 pounds. The bureau is now making simple glasses according to definite formulas, studying the methods of securing it free from bubbles, and other practical points. This is to be followed by an investigation of the method of annealing. Several glass manufacturers have visited the bureau already for suggestions as to the equipment for the manufacture of optical glass.

In connection with the election of a new president it is stated editorially in the *British Medical Journal* that the Royal College of Physicians of London has had ninety-seven presidents since Henry VIII., in the tenth year of his reign, granted a charter of incorporation. In granting this charter he said that his main reason was to check men who professed physic rather from avarice than in good faith, to the damage of credulous people; accordingly, after the example of other nations, he had determined to found a college of the learned men who practised physic in London, in the hope that ignorant and rash practitioners might be restrained or punished. The charter was granted to John Chamber, Thomas Linacre, Wolsey, Archbishop of York, and others. The college so constituted first exercised its privilege of electing a president by choosing Thomas Linacre for that office in 1518. Down to 1876, when Sir George Burrows ceased to be president and was succeeded by Sir James Risdon Bennett, a graduate of Edinburgh, the president had always been a graduate of Cambridge or Oxford. Since the spell was broken the presidents have all been graduates of the University of London, with the exception of Sir Andrew Clark, who was a

graduate of Aberdeen, and Sir William Church, who is a graduate of Oxford. The new president, Sir Frederick Taylor, elected March 29, the day after Palm Sunday, according to the statutes, is a graduate of London, having taken the degree of M.D. in 1870. He became a fellow of the college in 1879, was an examiner at various periods from 1885 to 1896, was on the council from 1897 to 1899, and was censor in 1904, 1905 and 1910. He has been the representative of the college on the senate of the University of London since 1907. He gave the Lumeian lectures in 1904 on "Some Disorders of the Spleen," and was Harveian orator in 1907. He is physician to Guy's Hospital; his predecessor, Sir Thomas Barlow, was physician to University College Hospital. Sir Richard Douglas Powell, who was president from 1905 to 1910, was physician to the Middlesex Hospital; his predecessor, Sir William Church, was physician to St. Bartholomew's Hospital; Sir Samuel Wilks, who preceded him, was physician to Guy's Hospital. Sir J. Russell Reynolds, who was president from 1893 to a few months before his death in 1896, was physician to University College Hospital; Sir Andrew Clark, who preceded him, was physician to the London Hospital; and his predecessor, Sir William Jenner, was physician to University College Hospital. At the present time the treasurer, the Harveian librarian and the registrar are members of the staff of St. Bartholomew's Hospital. The longest tenure of the office of president was that of Sir Henry Hallford, who was president from 1820 to 1844. The office is an annual one, but is, as a rule, held for five years.

THE proposed expedition to Paris of the University of Pennsylvania unit of physicians and nurses who will devote July, August and September to work in the American Ambulance Hospital, will sail early in June for France. Headed by Dr. J. William White, the party will be made up as follows: Surgeon, Dr. James P. Hutchinson; neurologist, Dr. Samuel J. McCarthy; assistant surgeons, Dr. Edmund P. Piper, Dr. Walter S. Lee, Dr. Arthur G. Billings and Dr. Peter McC. Keating; bacteriologist, Dr. Samuel Goldschmidt Gir-

vin, fellow in research medicine, University of Pennsylvania; nurses, Mrs. M. E. Spry, long chief clinic nurse of University Hospital; Miss Jackson and Miss Wagner; anesthetist, Miss Frazer. Explaining the undertaking and its purpose, Dr. White said: "In the early winter the executive committee of the American Ambulance Hospital decided, in the interests of medical science and teaching, and for the purpose of increasing the efficiency of the hospital in the case of large numbers of wounded, to invite certain American universities to send staffs from their respective medical schools to take charge of a floor of 150 beds for periods of three months each. The Western Reserve University took the term of January, February and March; Harvard, April, May and June, and is now on duty. Pennsylvania accepted for the earliest period she could obtain, viz., July, August and September. The other institutions invited were Johns Hopkins and the University of Chicago, which are expected to follow in the order named.

UNIVERSITY AND EDUCATIONAL NEWS

THE Circuit Court of St. Louis has confirmed the will of James Campbell, who left his entire estate to St. Louis University School of Medicine subject to a life tenure of his wife and daughter. His estate is valued at from six to ten million dollars.

THE late Ward N. Hunt, of Needham, Mass., has made Dartmouth College residuary legatee for \$20,000, to establish scholarship funds to be known as the Hunt scholarships.

It is stated in *Nature* that the Hutchinson Museum has been acquired by the Medical School of the Johns Hopkins University. The collection comprises original colored drawings; colored plates taken from atlases, books and memoirs; engravings, woodcuts, photographs and pencil sketches, in some cases with the letterpress or manuscript notes attached. The collection illustrates the whole range of medicine and surgery, but particularly syphilis and skin diseases.

SIR JOSEPH JONAS has given the University of Sheffield £5,000 to found a laboratory in connection with the applied science department, for testing metals and minerals, espe-

cially those involved in the production of steel.

DR. HENRY SUZALLO, professor of the philosophy of education in Teachers College, Columbia University, has been elected president of the University of Washington.

DR. HERMON C. BUMPUS, formerly professor of zoology of Brown University and director of the Museum of Natural History, will be installed as president of Tufts College on June 12.

At the University of Oklahoma, Professor F. O. Kent has resigned, and Dr. H. C. Gosard has been appointed instructor in mathematics.

DR. MOYER S. FLEISHER, who has been assistant in the department of pathology of the St. Louis Barnard Free Skin and Cancer Hospital, has been made assistant professor of bacteriology in the St. Louis University School of Medicine.

DR. SAMUEL H. HORWITZ has been appointed instructor in research medicine in the Hooper Foundation for Medical Research of the University of California, San Francisco.

DISCUSSION AND CORRESPONDENCE

ZOOLOGISTS, TEACHERS AND WILD LIFE CONSERVATION

TO THE EDITOR OF SCIENCE: In spite of the fact that we are familiar with the idea of historic cycles, it is a constant surprise, in watching advances in thought and action, to see that they are usually made not only without the cooperation, but often even with the opposition of those vitally concerned. This is true not only of the prophets of national defense, but is equally so of the protection and conservation of wild life. Strange as it may seem, the most experienced and best informed leader of this movement in this country states that the very people from whom every one should naturally expect the heartiest support—the professional zoologists and teachers of zoology—have been practically a negligible quantity in this defensive and constructive movement. Why is this true? There appears to be some fundamental weakness in this position. Can a factor in the problem be that we have become so engrossed in important

laboratory activity and in domestic animals that there is little interest and concern about wild life? Professor W. K. Brooks once said:

Is not the biological laboratory which leaves out the ocean and the mountains and meadows a monstrous absurdity? Was not the greatest scientific generalization of your times reached independently by two men who were eminent in their familiarity with living things in their homes?

Certainly Hornaday's "Wild Life Conservation in Theory and Practice" (1914) is a volume which should be read by every student of zoology and by all interested in general conservation problems. It is the outcome of a course of lectures given to the students of forestry at Yale, and is clearly an effort to enlist the interest and intelligent support of a younger generation of men, as it is on them that the hope for future progress largely depends. Hornaday clearly and forcibly shows the strenuous efforts which have been made in protecting our wild life from the plume hunters and the ordinary ignorant and selfish hunters of all kinds.

To bring out the sound rational foundation upon which protection is based, the economic value of birds is presented to show how they reduce the excessive numbers of insects in fields, orchards and forests, and the aid which hawks and owls give in helping keep down the number of vermin. The proper use of game is shown to be capable of producing millions of dollars worth of valuable food, as well as furnishing recreation for many people. Some of the New England states have already begun to profit by this on a large scale. In his enthusiasm for the cause of protection Hornaday does not go to the extreme and ignore the harm done by certain kinds of animals, or even occasional harm by kinds usually neutral or beneficial. The whole discussion is eminently sane and judicious.

Hornaday makes a strong appeal to the citizen not to allow a few people, a special class, who are reckless in the destruction of animals, and who really care nothing for their obligations to future generations, to advance unhindered in their devastation of our valuable fauna, which, if once lost, can never be restored. He says:

Seventy-five per cent. of the men who shoot game in America, in Europe, Asia and Africa are thoroughly sordid, selfish and merciless, both toward the game and toward posterity. As a rule, nothing can induce any of them to make any voluntary sacrifices for the preservation cause. They stop for nothing, save the law.

Such a view will appear strange and extreme to many, but at the same time it is, to some degree, a measure of one's familiarity with this aggressive campaign. And what will zoologists think of this statement?

And think, also, what it would mean if even one half the men and women who earn their daily bread in the field of zoology and nature-study should elect to make this cause their own! And yet, I tell you that in spite of an appeal for help, dating as far back as 1893, fully 90 per cent. of the zoologists of America stick closely to their desk-work, soaring after the infinite and driving after the unfathomable, but never spending a dollar or lifting an active finger on the firing-line in defense of wild life. I have talked to these men until I am tired; and the most of them seem to be hopelessly sodden and apathetic.

While this is equally true of educators at large, the fact is they are far less to blame for present conditions than are many American zoologists. The latter have upon them obligations such as no man can escape without being shamefully derelict. Fancy an ornithologist studying feather arrangement, or avian osteology, or the distribution of sub-species, while the guns of the game-hogs are roaring all around him and strings of bobolinks are coming into the markets for sale! Yet that is precisely what is happening in many portions of America to-day; and I tell you that if the birds of North America are saved, it will not be by the ornithologists at large. But fortunately there are a few noble exceptions to this ghastly general rule.

This quotation is not given to antagonize zoologists, but in the hope that some of their lethargy will be thrown off. If any one doubts the truth of this statement and resents it he is just the sort of person who should read this book. To the open-minded individual who has given no attention to this subject this book will be a revelation. The last chapter is replete with valuable practical suggestions for future constructive protective work. Repeatedly in this book important plans for the

future are outlined, such as the *conversion of our national forests into game preserves*. It is encouraging to know that there are already three endowments devoted to animal protection, one of \$340,000, a second for \$51,000 and a third of \$5,000. Of course these funds should be greatly increased as the period of relatively easy conquest is now over and the opposition is organized with powerful financial support. This contest is a permanent obligation.

The two concluding chapters of the volume are contributed by F. C. Wolcott. One is a valuable summary of the present status of private game preserves, and the other is a very useful bibliography on preserves, protection and the propagation of game.

With this volume and Hornaday's "Our Vanishing Wild Life" (1913) any intelligent person can become informed upon the present status of this phase of conservation.

CHAS. C. ADAMS

NEW YORK STATE COLLEGE OF FORESTRY,
SYRACUSE, N. Y.

AN EYE SCREEN FOR USE WITH THE MICROSCOPE

MOST beginners, as well as many practised observers, usually close one eye when using the microscope. This practise of "squinting" when one is using the microscope for any length of time causes a decided eyestrain. The other alternative of keeping both eyes open requires first of all considerable practise, and if it does not tend to strain the muscles of the eyes, it does give rise to a mental strain, if it may be so expressed; i. e., one has to concentrate his attention constantly on what is seen with the one eye through the microscope, otherwise the objects seen with the other eye will prove very distracting.

The writer, after having tried many different shapes and kinds of eye screens, has worked out one that seems to be the most efficient. It does away with the eyestrain of both types described above, and is very simple and inexpensive.

The accompanying sketch shows the outline of the screen. The material from which it is made is a composition called "vulcanized fiber board," 1.5 mm. in thickness and black in

color. This composition board is very tough and durable. It may be obtained from the Diamond State Fiber Company, Ellesmere, N. J. The screen is cut from this board with a knife or with heavy shears. A hole 2.3 mm.

in diameter (a hair larger than the outside diameter of the standard eyepiece) is bored by means of an extension bit at one end of the screen. The distance from the center of this hole to the middle point of the broad wing of the screen is 8 cm. The extreme length and width of the screen is 12.5 cm. by 7.5 cm.

If the composition board is not available, aluminum 1 mm. thick, painted black or dark green on both sides, will be found a good substitute.

The eyepiece of the microscope is slipped through the hole in the screen. The sketch shows the eye screen in position for use with the right eye, and to change to the left eye it is a matter of only a few seconds to take the screen from the eyepiece and invert it.

It will be found that the black surface of the screen is very restful to the eye not in use, and when one alternately uses the right and left eye, it is possible to use the microscope for a much longer period before the eyes become tired than without the eye screen.

MASS. AGR. EXPERIMENT STATION,
AMHERST, MASS.

EXHIBITION OF THE ROYAL PHOTOGRAPHIC SOCIETY

TO THE EDITOR OF SCIENCE: The Royal Photographic Society of Great Britain is holding its sixtieth annual exhibition in August and September of this year. This is the most representative exhibition of photographic work

in the world, and the section sent by American scientific men last year sufficiently demonstrated the place held by this country in applied photography. It is very desirable that American scientific photography should be equally well represented in 1915, and, in order to enable this to be done with as little difficulty as possible, I have again arranged to collect and forward American work intended for the scientific section.

This work should consist of prints showing the use of photography for scientific purposes and its application to spectroscopy, astronomy, radiography, biology, etc. Photographs should reach me not later than Thursday, July 1. They should be mounted but not framed.

I should be glad if any worker who is able to send photographs will communicate with me as soon as possible so that I might arrange for the receiving and entry of the exhibit.

SCIENTIFIC BOOKS

Report on Gyroscopic Theory. By SIR GEORGE GREENHILL. Reports and Memoranda, No. 146, Advisory Committee for Aeronautics. London, T. Fisher Unwin, 1914. Pp. iv + 278, with 49 illustrations. Price 10 shillings.

Many people wonder at the expenditure of time and energy given by the mathematician to subjects like the theory of groups and differential equations. Others can not understand why men of the ability of Klein, Perry and Crabtree should lecture upon the theory of the top. Still others fail to see in the studies made by Maxwell of his spinning top in an agate cup, or of Sommerfeld and Noether on the gyroscope, anything to justify a student in following in their footsteps. And yet, when we reflect that the spinning top illustrates a group of motions, that its theory involves the differential equation at the very outset, that the earth is merely a moderate-sized top spinning in space, that the solar system is a somewhat larger one, and that many nebulae are solar systems in formation, the subject assumes

a different aspect, even to the man in the street. And when he further reflects that the stabilizing gyroscope, now made in large numbers by Sperry's company, is used on the aeroplanes above the firing lines in the great war, and acts as a literal balance wheel on the super-dreadnoughts of the warring powers and can be bought in the offices of the makers in any of the large capitals of the world, this same man in the street begins to see that the theorist may touch upon the very practical and that the practical man may well afford to look to the man of theory for help in the affairs of the real life of the present day.

It is such popular considerations as these that may well lead the man of dollars to welcome, even if he can not understand, a monumental treatise like this which Sir George Greenhill, with his usual modesty, has called a simple report. To the general man of science the work will mean much more, even if he too shall fail to read 278 large quarto pages devoted chiefly to mathematics. But to students of analytical mechanics, and particularly to those who look for applications of modern mathematics to dynamics, the work will stand as a monument of patient research on the part of a man who works *con amore* and with an extended vision in a field of rapidly increasing importance.

Sir George Greenhill always writes as he talks, and he never talks like the man whom he delights to refer to as "a mere mathematician." As he sits at the head of a work table in his quaint room in Staple Inn—the room in which Dr. Johnson may have written *Rasselas*—and talks of his labors on the gyroscope, he is a mathematician for about a minute, a man with the zeal of a boy for another minute, a charming raconteur of stories of his master, Maxwell, the minute later, and an appreciative student of his friends Klein and Sommerfeld in the next unit of time. And this description characterizes his addresses, his books, his memoirs and his reports—they are all human, the product not merely of the mathematician, not merely of the student of dynamics, not merely of the experimenter in the laboratory, but always of the big-hearted man.

And so it is with this report. It is filled with mathematics in which elliptic functions, long a favorite study of Sir George's, plays an important rôle; but the reader is continually running across such homely illustrations as those a teacher might use in the classroom—the illustrations of bicycle wheels, stepladders, clock hands, reflections in a mirror, plumb lines, balancing on a knife edge, tops, children's hoops, race wheels, motor cars, the motor omnibus, spinning cards through the air, Whitehead torpedoes, the monorail carriage, and the like—just the sort of things that those who have used the problems in the author's calculus have delighted to find for interesting a class.

The report is divided into nine chapters. Chapter I. relates to steady gyroscopic motion, with applications to the problem of the precession of the equinox and to the gyroscope as a stabilizer. Chapter II. continues the applications of the gyroscope, in particular with reference to ships, the Brennan monorail carriage and the Bessemer saloon. Chapter III. relates to the general unsteady motion of the gyroscope, and to the figures resulting therefrom—for example, to the rosette curve described by Klein. Chapter IV. deals with the geometrical representation of the motion of a top, and in particular with the work of Darboux. Chapter V. treats of the algebraic cases of top motion, and in particular of the section problems, a subject continued in Chapter VI. Chapter VII. relates to the spherical pendulum and related topics, Chapter VIII. to such topics as the gyroscope on a whirling arm, and Chapter IX. to the dynamical problems of steady motion and small oscillation.

It is not intended in this brief review to do more than call attention to the general nature of the work. The practical value of the subject has come to be recognized in this war as never before, and it is well that we have in one place the body of theory which students of the subject would otherwise have to search for in many pamphlets, books and periodicals. The report lays no claim to any important discovery, but it may fairly claim to bring together in convenient form the mathematical

theory of the gyroscope as far as it has been developed up to the present time.

DAVID EUGENE SMITH

TEACHERS COLLEGE,
COLUMBIA UNIVERSITY

Monographs on Biochemistry. Soil Conditions and Plant Growth. By EDWARD J. RUSSELL, D.Sc. (Lond.), Director of the Rothamsted Experimental Station, Harpenden; with diagrams. New Edition. Longmans, Green and Co., 1915. Pp. 150.

This is the third edition called for within three years of the best book on the soil which has yet been written. A new chapter has been added on "The Relationship between the Microorganic Population of the Soil and the Growth of Plants." A number of minor changes and a few of considerable importance have been made in the original text, usually because of recognition of literature non-existent when the text was prepared originally. The versatility of Dr. Russell is astonishing and the wealth of his information is prodigious. And yet he has told his story in some 170 pages without an undue crowding. In fact the book has "charm" and is easily read. The professional chemist, physicist and bacteriologist will find it a mine of information most interestingly woven together, but with frequent references to original authorities. And at the same time the layman can get a purview of the complex system involved in plant production in an understandable story.

Not only is the book the best in its field relatively, but it is very good absolutely. But it is not ideal, and probably most of the experts will feel that its accents should be altered and even that some of the statements should not have been made as they are. For instance, the reviewer should prefer to see the relation between moisture content and the measurable physical properties of the soil given more prominence; and the dynamic as contrasted with the static properties of the soil developed more definitely. One is left with a too hazy idea of the colloidal properties of clay and their importance to the soil, and the purely hypothetical calcium bicarbonate is called upon rather frequently to explain things without

the slightest intimation that its claims to existence are any less valid than any other compound. It is stated that the water in the soil is weakly held, when as a matter of fact the film moisture is held by probably enormous stress and the reader is left in confusion as to just what the author means. It is not the simplest view (page 77) that the mineral particles are coated with a colloidal complex, but that the so-called colloidal properties of the soil are those resulting from the relatively vast surface presented by the "clay" portion of the soil; and it would be more satisfactory to utilize the fact that the solubility of calcium carbonate is increased by increasing the partial pressure due to carbon dioxide than assume the existence of a compound which can not exist at any gas pressures existing in the soil.

But when there is so very much that is admirable it makes one feel ungracious to continue criticisms of details. The book deliberately makes its major appeal to biologists, and the greater part of the text is devoted to the biological properties of the soil. But its most striking feature is the skilful handling of the contrasting views of soil chemists and physicists. While it is probable that others as well as the reviewer will not entirely agree with the author's presentation of recent controversies, every one will undoubtedly recognize the evident intent of fairness and careful effort to summarize correctly. It is very probable that no one could at this time make a better presentation than has Dr. Russell, although we may each hope that some future edition of his book may accord more closely with our several individual views. Fortunately for the development of this branch of applied science, modification of the personal views of most of the prominent workers is commendably frequent and frank. A satisfactory index and a well-selected bibliography are retained in the present edition.

Dr. Russell's monograph is not suited to class-room use of undergraduates in our agricultural colleges, though such undergraduates would undoubtedly profit by reading it. The book will prove a mine of suggestions to the advanced scholar and investigator and should

prove an eloquent testimony for the view that the time has now come when our universities can afford to recognize that some agricultural subjects have developed to a point in dignity of effort and scholarship where they might profitably be included in the curriculum beside older and more familiar academic fields. The advances of the last few years in secondary rural education and in the standard of our American agricultural colleges is worthy cause of gratification. But it is almost a disgrace that our principal universities are utterly failing to train and provide leaders and teachers for what must always be our country's chief field of endeavor; and to recognize that the art of agriculture is passing—rapidly passing in the United States—from the avocation of the artisan to the profession of the highly trained specialist. Dr. Russell's book will not be the least of the instruments to bring about the change.

FRANK K. CAMERON

SHARK INTOXICATION¹

The flesh of the economically very important Greenland shark (*Somniosus microcephalus*), a shark usually between 6 and 14 feet in length occurring abundantly in the Arctic Ocean and ranging southward to Norway, the Faeroes, Iceland, Cape Cod, Oregon and Japan, has long been known to possess certain poisonous qualities.

It is not known to what extent the poisonous nature of the flesh of this fish is shared by that of other species of sharks, some of which, at least, appear to be quite harmless; but in view of the possibility that in the near future the flesh of some of our more abundant species of selachians may be placed on the market for the purpose of providing a cheap supply of good fresh food, it would seem opportune to call attention to what is known in regard to the undesirable qualities of the flesh of the Greenland shark in order that similar qualities in the flesh of other species, if present, may be immediately detected.

Mr. Ad. S. Jensen, of the zoological museum of the University of Copenhagen, has re-

¹Published with the permission of the secretary of the Smithsonian Institution.

cently published² the following excellent summary of all that is definitely known concerning shark intoxication.

In North Greenland, where the dog plays such a large part as draught animal for the sledge, the shark fishery has the additional importance of providing food for the dogs. In the dried condition especially shark flesh is an excellent dog food; it gives the animals strength to sustain prolonged exertions without being fatigued. In the fresh condition, on the other hand, it is dangerous for the dogs; when they eat a quantity of it they become heavy and subject to giddiness (they are said to be "shark-intoxicated"); on driving a short distance with them they begin to hang their ears, tumble from side to side and at last fall down in cramp convulsions, after which they can not be got to move from the spot; in a couple of minutes the dog may recover, but when it runs again the whole body quivers and the dog has no power to drag; at the same time, especially when the weather is warm, the animal has diarrhea, its feces are "squirted out" as greenish water; sometimes the animal dies of the sickness. At places where shark food is plentiful, however, the dogs accustom themselves to eating a large amount of it without being sick; but if they are driven in the warm sunshine they may be very bad from it. From dried shark flesh the dogs never become "shark-intoxicated," yet they can also become sick from it, as dried shark meat tends to swell out in the stomachs of the dogs; the Greenlanders therefore advise to give the dogs only small rations of dried shark meat and first to cut the meat into long and narrow strips, so that the dogs do not gulp down the whole at once, but can regularly work through it with the teeth.

To explain these phenomena it may be said that the fresh shark flesh contains a compound that acts like alcohol; when the flesh is boiled, the poisonous stuff is removed and the dogs can then eat more of it without suffering than when the meat is fresh. The poisonous substance is probably present everywhere in the body of the shark, also in the cartilage. Rink was of the opinion that the danger of the shark's flesh was due to its containing a large amount of saline fluids, which were totally swallowed down when the flesh was eaten in the frozen condition. To clear up the matter I consulted the veterinary surgeon S.

² "The Selachians of Greenland" ("Sæterryk af Mindeskrift for Jøpetus Steenstrup") pp. 12-14, 1914.

Hjortlund, who lived for a couple of years in North Greenland and there made investigations on the infectious sickness of the dogs; he has kindly sent me the following information.

"These cases of poisoning, which in Greenland always occur after eating fresh, raw meat of the Greenland shark (*Somniosus microcephalus*), both in men and dogs, is without doubt due to a specific poison (a toxin) which occurs in its body. Nothing indicates the correctness of Rink's view, that the poisonous nature of fresh shark meat was due to the large quantity of saline fluids it contained, whilst many things speak against this view.

"Meanwhile, however, the question has not yet been scientifically investigated and all we know about it is exclusively based on empirical observations.

"The clinical symptoms, of which—as mentioned above—tiredness, dullness, uncertain gait, sensory disturbances and a profuse diarrhea are the most in evidence, depend in virulence on the quantity of meat taken, but in dogs can also be intensified in mild weather and with bodily exertion. In men, where the poison causes a similar complex of symptoms, the sense disturbances both objectively and subjectively give the same impression as acute alcohol poisoning. The symptoms of poisoning may last a shorter or longer time, from a couple of hours to a couple of days. They may be very weak, almost unnoticeable, when the animal has only taken a small quantity; on the other hand dogs have several times been known to die under violent symptoms, almost apoplectic in character, a short time after they had eaten large quantities of shark meat.

"Of importance in judging of the nature of the poisonous stuff or stuffs is the fact that the animals can gradually be accustomed to taking larger and larger quantities of it. Obviously antidotes can be produced in the body of the dog, which counteract the activity of the poison; in other words, the animal can to a certain degree become immune, and this gradually occurs spontaneously at places where the dogs have constantly the opportunity of eating fresh shark meat.

"The poison, however, is soluble in water and can thus be extracted from the meat by thorough washing. How far, on the other hand, it is destroyed by heating to temperatures below 100° is more doubtful. In any case the transformation here must proceed slowly; for according to all reports the meat must be cooked in two to three different waters before one can be certain that it

is not poisonous. It is most reasonable to assume that it is resistant to such a temperature.

"The usual method in practice of preparing the shark flesh so that it may gradually lose its poisonous qualities is to cut the meat into thin strips which are hung up to dry in the sun and air; it thus loses its large quantity of water, and gradually its poisonous qualities disappear, so that it becomes a rather good food for the dogs, though it must still be used with caution and preferably mixed with a little blubber.

"Regarding the seat of the poison in the body of the shark we have the most divergent opinions; some assume that it is only in the musculature, others that it is exclusively present in the cartilage and others again that it is chiefly found in the peritoneal and spinal fluids, as it has been found that these fluids produce a severe pain when received in the eye. A proper judgment on these matters, however, will only be obtained by means of a special investigation of the poison, and such at the same time would elucidate its chemical composition, its physiological properties and various biological reactions."

SPECIAL ARTICLES

THE CROWN-GALL OF ALFALFA

DURING the past two years the writer has been engaged in studies upon the life-history of the organism described by Magnus¹ in 1902 under the name of *Urophlyctis alfalfa*. It seems best to publish a brief statement of the results so far obtained, pending further studies.

1. The "resting spores" when placed in water cultures develop into sporangia.

2. Within these sporangia are formed motile spores of two sizes; usually one large spore and many small ones are formed in the same sporangium.

3. One or several small spores may become attached to one large one. Only one remains permanently attached. It has not been determined whether or not this attachment is in the nature of a sexual fusion. If so, the large spores and small spores are obviously capable

¹ Magnus, P., "Ueber in knolligen Wurzelanwuchsen der Luzerne lebende *Urophlyctis*," *Ber. der Deut. Bot. Gesell.*, 20, 291-96, 1902. One plate.

of functioning as sexually differentiated gametes.

4. The motion of the large spore continues after the attachment of the small spore.

5. The small spores, the large spores and the united spores (zygotes?) become amoeboid after a period of motility.

6. In the amoeboid state, singly or in groups, these bodies may be observed to move on the surface of the host.

7. In infected soil young alfalfa seedlings develop galls in which plasmodia are found.

8. In older galls similar plasmodia are present which ramify through the tissues of the gall. Previous to spore formation the parasite becomes massed in cavities formed by the destruction of the host tissue.

9. The resting spores are formed in these cavities, apparently by division of the parasite into many cells.

10. The content, cytoplasm and nuclei, of the resting spores in the dormant condition, corresponds to that of the plasmodium in the stage immediately preceding spore formation.

The presence of a plasmodium as the vegetative stage of the parasite and the entire absence of a mycelium at any stage suggest that possibly the organism should be removed from the genus *Urophlyctis*.

UNIVERSITY OF WISCONSIN

A PRELIMINARY NOTE ON THE FOOD HABITS AND DISTRIBUTION OF THE TEXAS HORNED LIZARDS

RANDOM examinations of stomach contents, made by various workers during the past forty years, have indicated that *Phrynosoma cornutum*, the Texas horned lizard, is of great economic importance. To determine its status as a valuable animal, an examination of four hundred and eighty-five stomachs has been made. As only a small per cent. of the animals found in the field were captured and killed, several facts—besides the principal one—concerning this animal have been disclosed.

The Texas horned lizard, unlike the other species of the genus, is distinctly not a desert form. Its area of distribution is quite extensive, going northward into Kansas, southward

far into the Mexican table land, and westward into Arizona; but, clearly, the area of its greatest abundance is the north and south strip of Texas known as the Black and Grand prairies. This strip of country includes the cities of Fort Worth, Dallas, Waco, Austin and San Antonio—in fact all of the large cities of the state except Houston and Galveston; and is preeminently the best part from an agricultural standpoint. Within this area, where conditions are at all favorable, the *Phrynosoma* population averages at least thirty to the acre. This is despite the fact that for a number of years these lizards have been captured and sold to visitors from the east.

The life history has not been well worked out, but the newly hatched young begin to appear by the first of August; so that it is safe to say that the ordinary agricultural operations such as spring and fall plowing, do not interfere with the life cycle. The natural enemies are few and unimportant, being mainly road runners and opossums.

The stomachs examined included the following forms: four species of ants; four species of weevils (very few boll weevils); four species of bees (mainly miner bees); eight species of beetles; three species of stink bugs; nymphs of grasshoppers and allied Orthoptera; five species of flies; and a few caterpillars, some of which have not yet been identified. The noxious forms found overwhelmingly outnumbered the useful forms.

Agricultural ants were found in 80 per cent. and stink bugs in 60 per cent. of the stomachs. Neither of these is much subject to the attacks of birds. Obviously this enhances the value of *Phrynosoma*. Incidentally, there was a remarkable consistency or homogeneity in the contents of the individual stomachs. For example, in one case, nearly all of the forms present would be Hymenoptera; in another, nearly all would be Heteroptera, etc. This could mean that individuals acquire a taste for sour food, or fatty food, etc.; or, what is more likely, that the same individual requires from time to time certain special elements in its food.

From the data thus far assembled, it can be

safely affirmed that the horned lizards of Texas are of tremendous importance to agriculture in that region; and may, perhaps, play as important a part there as does the common toad in the better watered regions of the United States.

ADVANCEMENT OF SCIENCE
SECTION D—MECHANICAL SCIENCE AND
ENGINEERING. II

The Highways of Hawaii: H. K. BISHOP.

Before the days of county government, the central government of Honolulu, under the superintendent of public works, improved many highways with first-class water-bound macadam, in many instances with a telford base. Under the county form of government, the county took charge of the maintenance of the roads already built and the construction of all new ones. It is needless to say that this system has proven unsatisfactory and unproductive of good results in general.

In 1910 and 1911, by legislative action, provision was made by the territory, to raise funds by means of a bond issue and to put the work of road improvement under this issue in the hands of a commission, to be known as the Loan Fund Commission. The writer was engaged in September, 1911, by the Hawaii Loan Fund Commission to prepare plans and specifications and to superintend the construction of the belt road improvement on the Island of Hawaii. The belt road, which is the main highway of the island, approximately parallels the coast line at a greater or less distance entirely around the island, a distance of approximately 250 miles.

In the work of improvement on Hawaii, the general plan adopted was to use water-bound macadam with a telford base in the wet sections, and bituminous macadam in the dry sections. It was also planned to give the water-bound macadam a surface application of bituminous material when the macadam had become sufficiently compacted to make such a treatment successful.

The greatest need of Hawaii is some form of territorial aid to the counties similar to that adopted by the majority of the states of the Union. Hawaii is also in need of some form of centrally controlled highway department which will insure the standardization of road work and a

continuity of the policy. The territory is going through practically the same experience that every state in the Union has been through in its road work.

Service Tests on Various Classes of Pavements:
H. W. DURHAM.

A solid unyielding foundation is a necessity for all road construction, but type and details are purely a local question. Much unnecessary confusion is caused in road discussion by inability to discriminate between cause and effect and by laying more importance on details of specifications than on the result they obtain.

The only true test is that of service under conditions of actual use. Final selection must be made among a limited number of types and suit a limited number of conditions. Carrying intermediate operations in the problem of selecting road types to extremes of refinement is unnecessary in that the conditions to be satisfied are few, and the final selection must be from among these classes.

Service Tests of Stone Block Pavements in Brooklyn: H. H. SCHMIDT.

About five years ago studies were begun of the various granite pavements in the borough of Brooklyn, with a view to determining, if possible, the causes which created the objectionable features. Observation showed that certain granite blocks polished under traffic, so that they became extremely slippery; some wore down rapidly at the edges, causing the top of the block to become turtle-backed, which made the pavement extremely rough; some blocks were found which disintegrated under traffic, and still others were extremely rough and not well-shaped, owing to the fact that they were made from a granite which had improper cleavage planes. We learned from the service tests of the stones actually subjected to traffic, that the mineralogical composition of the granite, the presence or absence of certain minerals, and the proportions in which they occur, as well as the size of the crystals, all had a direct bearing on its value for paving purposes.

After a conclusion had been reached as to the most desirable granite, a study of the size, dressing and filler was taken up. With the use of a concrete base, the extreme depth of the block was unnecessary, and the depth was therefore reduced from eight to five inches. With modern granite block it is possible to obtain joints averaging from a quarter to three eighths of an inch. The blocks are laid so close together that a considerable area of

the blocks touch one another, thus giving stability to the pavement, even without the joint filler. It is unnecessary with the modern granite block pavement to use paving gravel, and the modern practice favors the use of a mixture of tar or asphalt with hot sand, poured into the joints.

Wood Block Pavements: W. P. TAYLOR.

The Value of the Absorption Test on Wood Blocks:
GEORGE W. TILLSON.

When municipal engineers were considering the advisability of laying treated wood block pavements some twelve or fourteen years ago, it was uncertain as to just what should be the requirements of the specifications. It was felt that it was necessary to prevent the blocks from decay and also to treat them so that they would be stable under all climatic conditions; that is, they should not absorb so much water as to swell and cause the pavement to bulge, during a wet spell, nor should they shrink too much in dry, hot weather, so that they would become loose.

After careful consideration, it was decided to require an absorption test of the blocks. The test provided that after being dried in a kiln at a temperature of 100° F. for 24 hours, the blocks should not gain in weight more than 3 per cent. during immersion. Pavements were laid under this specification in 1903 and 1904, and on one street with a preservative that did not contain any resin, but was a specially prepared oil. The blocks obtained did, however, conform to the requirements as to weight and absorption. These pavements have been in use 10 and 11 years, without any expansion joint, and have required almost no attention on account of the instability of the blocks. In certain cases where pavements were laid not under the supervision of the city, so that the absorption test was not applied, the pavements did expand to a very considerable extent.

The city of New York is the only municipality of which the writer knows where the absorption test is required, and it is also the only city, in his knowledge, where an expansion joint is not used. The writer firmly believes that with a heavy oil treatment of 20 pounds and a specification requiring an absorption test, as given above, satisfactory results can be obtained without an expansion joint.

Sand Cushion vs. Mortar Bed for Wood Block Pavements: THEODOR S. OXHOLM.

In this country it has been the custom for many years to lay wood block pavement on a concrete base with a cushion of sand or a bed of mortar between the base and the blocks. A sand cushion is intended primarily to smooth out the

roughness and inequalities in the concrete, so that the blocks might rest evenly thereon. Secondly, the yielding surface of the sand permits the roller to press the blocks into it until they present a smooth surface, adjusting the slight inequalities in the depth of the blocks, and thirdly, the sand has a slight resiliency and protects the blocks somewhat from surface wear. The mortar bed performs the same office as the sand as an equalizer of the concrete surface and the surface of the finished pavement, but there the similarity ceases, for, as the mortar gradually sets it forms a hard unyielding bed for the blocks to rest upon, sacrificing resiliency for immobility.

There are two objections in the writer's opinion to the use of a sand cushion. First, when cuts are made for any purpose through the pavement, it frequently happens that weeks and months elapse before repairs are made; during this time, storm water works its way between the blocks and base and disturbs considerable quantities of pavement that will have to be relaid. This is especially noticeable on streets with a considerable grade, and could not occur with a well-set mortar bed. Second, it would seem that even the slight resiliency of the sand cushion would mean the unstable condition of each block with respect to its neighbors, and a consequent lack of support on sides and ends which is of the utmost importance. The one objection to a mortar bed has always been that the mortar has been mixed damp and time must be allowed for it to set hard (three or four days), before traffic could be admitted, whereas wood block pavement on sand cushion can be thrown open for traffic as soon as completed. The writer has overcome this objection by mixing the mortar dry, and allowing it to set as moisture reaches it through the joints which are always of sand. The roller and immediate traffic work the blocks down to their final beds before the mortar sets. Work of this kind has been examined at plumbing cuts and it has been found that the mortar was set up hard, though traffic had been allowed on the new pavement as soon as completed, and the surface was still uniform.

Cement Concrete Pavements: FRACY H. WILSON.

The author states that the basic principle of the modern concrete road goes back to the ancient Roman roads in that the latter involved the use of puzzolana, the cement used by the Romans, while Portland cement is used as a binder in the modern concrete road.

The author emphasizes the following as conspicuous advantages of the concrete road:

Absence of mud and dust.

Roads passable at all seasons.

An even but gritty surface texture which prevents horses and cars from slipping.

A flat crown making every foot of road surface available for traffic.

Extreme durability increasing with age and exposure to the elements.

Imperviousness to frost and heat.

Moderate first cost and minimum maintenance cost.

With the establishment of expansion joints at proper intervals the cracking of concrete road had been practically eliminated, but when cracks do occur they are filled with tar and sand at small expense, this treatment, to all practical purposes and intents, restoring the slab to its monolithic character.

The paper describes structural methods and calls special attention to the importance of using only the best quality of materials, strict observance of specifications and careful workmanship.

Cement Concrete Pavements with Thin Bituminous Surfaces: W. H. LUSTER.

The concrete surface standing exposed to the weather and chance traffic for fourteen days becomes dirty, and before the hot bitumen was applied it was thoroughly cleaned in order to bond the two materials. Cleaning is of the utmost importance, and to that end the concrete was swept first with wire brooms, then with ordinary house brooms and then flushed with water under pressure by means of fire hose, and while the water was flowing was swept in the direction of the flow to the drainage inlets, but even then there remained the cement scum, or laitance, which always forms at the low spots to which it drains, and there hardens; this must be removed, for it is always smooth and no bitumen will adhere to it, and even if it did, it is not a suitable material for road metal, as it is soft and brittle and soon disintegrates under traffic.

The refined tar was applied hot by spraying under pressure from a moving auto truck tank, containing about one thousand gallons. A comparison of area covered with the capacity of the tank showed that the quantity spread was about one gallon to every three square yards. The bitumen was then covered with a coating of fine quartz gravel, the largest size grain being three eighths of an inch in diameter, and spread in the proportion of one cubic yard to one hundred square yards of surface. The street as thus pre-

pared was closed for twenty-four hours, after which traffic was admitted.

This thin bituminous coating acts in four capacities: First, it waterproofs the surface; second, it acts as a carpet and deadens the noise of traffic; third, it affords good foothold for horses, and fourth, it prevents abrasion of the concrete, thus prolonging its life.

Topeka Bituminous Concrete Pavements Constructed with Tar Cement: PHILIP P. SHARPLES.

The Topeka bituminous concrete is shown to be a revival of types of pavements laid with coal-tar cement twenty-five years or more ago.

The vulcanite pavements of Pittsburgh and tar concrete pavements of New England are described and compared with Topeka specifications.

The precautions necessary to secure successful work with the Topeka specification using coal tar cement are given.

Bituminous Pavements with Two or More Layers of Bituminous Concrete: ARTHUR H. BLANCHARD.

In cases where one product of a stone-crushing plant is used for the aggregate of the wearing course of a bituminous concrete pavement and this product is composed of broken stone varying but little in size, let us say from $\frac{1}{2}$ in. to $1\frac{1}{2}$ in., it will be advisable to use two layers of bituminous concrete. If the above product was used for the first layer and was constructed with a compacted thickness of from $1\frac{1}{2}$ to 2 inches, the second layer might properly be composed of broken stone from $\frac{1}{2}$ to $\frac{3}{4}$ in. in size and spread about $\frac{1}{2}$ in. to $\frac{3}{4}$ in. in thickness. After the second layer had been rolled the pavement could be finished with or without a seal coat of bituminous cement and a dressing of uncoated stone chips. This method is suggested in order to secure with the above type of broken-stone product a surface of the wearing course which will be as dense as when a product ranging in size from $\frac{1}{2}$ inch to $1\frac{1}{2}$ inch is used and the pavement finished with a seal coat of bituminous cement and stone chips.

From a historical standpoint it is of value to note that an English bituminous pavement of similar type was described in the *Engineering Record* of July 23, 1898. The fundamental principles involved have been made use of in the many successful bituminous concrete pavements constructed in England during the past fifteen years under the trade names of Tarmac and Quarrite.

Bituminous Macadam Pavements (Penetration Method): FREDERICK STEELE STRONG.

In determining the quantity per square yard of bituminous material to be used in construction of a bituminous macadam pavement there are four paramount functions to be considered: First, the nature and consistency of the bituminous material; second, the quality of the stone; third, the depth and sizes of the course; fourth, the kind of traffic and severity of climatic conditions.

With this data, the following equation has been deduced for the proper amount of binder to be used in cases where the stone is of low crushing and abrasive strength, this classification not to include any stone which is so poor as to be questionable or worthless. Let Y represent the number of gallons to be used per square yard. Let X represent the depth of the top course in inches. Then $Y = 9/10 X$. For instance, with stone of low test, and depth of stone of 2 in., we determine that the quantity of binder should be approximately 1.8 gals. per square yard; and by using this equation again, it is found that for a depth of 3 in. the amount of bituminous material should be 2.7 gallons per square yard.

This binder is to be applied in two applications, the first to be two thirds the full amount and the second the balance, and the application is made by pressure machine. I believe no top course for a road of this type should be less than 3 in. in depth. The best stone available should be used even if its cost would entail the use of cheaper material in bottom course, but by this I do not depreciate the importance of a foundation, as without this any road is worthless.

Some Ways to Differentiate between Bitumens: GEORGE P. HEMSTREET.

The Present Status of Adhesive and Cohesive Tests of Bituminous Materials: JOHN S. CRANDELL.

During the past year the writer has made a series of tests to determine the binding values of a number of bituminous binders. The first tests were made as follows: Cylindrical briquets 25 mm. high \times 25 mm. diameter, composed of stone, sand, filler and binder were molded under a pressure of 500 kilos per square inch, or 750 kilos per square inch, and were then allowed to season. They were then tested in the small Page Impact Machine that is used for the cementation test of stone. The number of blows required to break or crush each briquet was recorded. Different percentages of the ingredients were tried. It was found that pieces of crushed stone were cracked while in the molding machine. Other mechanical

difficulties developed, and it was decided to increase the size of the briquets to 35 mm. high X 50 mm. diameter. No difficulty is now found in molding the specimens.

These tests, which the writer has called binding value tests, furnish (a) an easy means of comparing the adhesive and the cohesive strength of binders, (b) a control of the amount of binder to use, and (c) a quick way of determining the correct amounts of stone, sand and filler to use.

The Purchase of Asphalt and Asphaltic Cement on the Bitumen Basis: W. H. BROADHURST.

To those familiar with the nature and composition of asphalts and asphaltic cements, the advantages from an economic standpoint of purchasing these materials on the bitumen basis is obvious. The bitumen, or carbon-bisulphide-soluble content of an asphalt, being the cementitious material which binds the mineral aggregate of an asphalt pavement or bituminous concrete together in a compact mass, it follows that, without giving consideration to the character of the insoluble material, or whether the same improves the value of the asphalt as a paving material or is deleterious, the greater the percentage of the insoluble material, the less the efficiency of the asphalt in respect of the number of square yards of roadway per ton of asphalt a given asphalt or asphaltic cement will lay. Hence to place all asphalts in competition on an economically sound or even basis, the same should be bought on the basis of the contained bitumen. Specifications for the purchase of asphalt should therefore be drawn outlining the requirements, first as to quality, and secondly, as to quantity of contained bitumen, instead of requesting merely bids for refined asphalt, or asphaltic cement, which is a very prevalent custom to-day with many municipalities operating municipal asphalt repair plants and state highway commissions purchasing asphaltic cement for state roads.

A Change in the Asphalt Pavement Specification: JOHN MARTIN.

Allowable Maximum Penetration of Various Types of Asphalts for Use in the Several Kinds of Bituminous Pavements: H. B. PULLAR.

The writer would state that in his own opinion there is no set rule which can be adopted or followed in setting a maximum penetration for any type of asphalt or any type of bituminous construction; that it is necessary to consider the local conditions in conjunction with the various bituminous materials on the market and to incorporate them in such a way into the specifications so

as to get most satisfactory results. The writer further believes that the maximum penetration is merely one of the many small but important details of construction which must be considered separately for each different piece of work, and that in order to get bids on bituminous materials specifications should be so drawn with limits sufficiently open to produce maximum competition with reverting specifications on bituminous materials, these reverting specifications to be drawn up with limits narrow enough to exclude anything but the highest quality of material for that particular type of bituminous material and at the same time not be unjust to the producers of the different kinds of bituminous materials. Under this kind of a specification it is possible to take into consideration all of the local conditions, the different characteristics, and the inherent qualities of the different bituminous materials and to incorporate in these specifications the allowable maximum penetration for the particular type of pavement and under the particular conditions it is to be constructed, and the writer believes that it is only by this method that the most successful results can be obtained.

A Review of the Use of Bituminous Materials in Highway Engineering during 1914: ARTHUR H. BLANCHARD.

During 1914 the following noteworthy developments have been noted:

In specifications for bituminous materials there has been a tendency to adopt a group of type specifications in place of a blanket specification. By this method engineers have been able to secure the most suitable grade of a given type of bituminous material for a given method of construction, as it is practicable to specify desirable limits for each type rather than have wide limits, as is necessary in blanket specifications. Another self-evident advantage is that more uniform material may be secured by this method.

Bituminous surfaces have been constructed (a) with more attention to the physical properties of the road metal composing the wearing course and the requisite dryness and cleanliness of the surface prior to application of the bituminous material; (b) using to a greater extent bituminous materials which do not require from several days to three weeks to set up; (c) generally employing pressure distributors in place of hand methods and gravity distributors.

In the construction of bituminous macadam pavements there has been a noteworthy tendency to (a) use bituminous cements of a lower penetra-

tion than formerly and (b) more thoroughly roll the wearing course prior to the first application of bituminous material.

Bituminous concrete pavements have increased in popularity in many sections of America. There has been a general tendency to use carefully heated aggregates and employ mechanical mixers. Bituminous materials of lower penetration than formerly are used in bituminous concrete, the aggregate of which is composed of one product of a stone-crushing plant, the sizes of stone ranging from $\frac{1}{2}$ in. to $1\frac{1}{4}$ in. The largest contract for this type of construction during 1914 was the Ashokan Highway, 37 miles in length, built by the board of water supply of New York City.

The third session was held on the morning of Thursday, December 31, Vice-president Dr. Frederick W. Taylor and Mr. O. P. Hood in the chair, with an attendance of about 70. The program of the session was as follows:

Vice-presidential Address: *Safety Engineering*: O. P. HOOD.

Engineering and Industrial Regulations for Promoting Safety in Industrial Establishments: JOHN PRICE JACKSON.

Recent Developments in Precise Leveling: WILLIAM BOWIE.

There should be in each city and state and throughout the whole country connected systems of leveling to form the basis and give the datum for the ordinary spirit or wye leveling.

The nation has, at present, about 31,000 miles of precise leveling with more than 13,000 substantial bench marks. The elevations in the precise level net are referred to mean sea level. The mean surface of the water at the starting points was derived from long series of tidal observations. Mean sea level is the natural and the best datum for a level net. In the first place, it is a fundamental datum, for it can be reproduced; again, with it, leveling can be started at many places with certainty that when the different lines are joined the agreements will be close. Also, leveling by different nations will agree when it is connected on the international frontiers.

There should be only one datum for the whole country, and this is only possible after the level net has been extended to such an extent that no place is far from a precise level bench mark.

The instrument used by the Coast and Geodetic Survey in its precise leveling is generally known as the "United States Coast and Geodetic Survey precise level." Its noteworthy features are that it is

made of an alloy of nickel and iron which has a very low coefficient of expansion; its bubble is set down into the telescope near the axis of collimation; and its binocular system, by which the observer can see the bubble, cross wires and rod at the same time. The instrument was designed and made in the Coast and Geodetic Survey Office. It has proved very effective in enabling the observer to avoid or eliminate many of the errors which were in the leveling done with the older types of instruments.

All lines are run at least twice, in opposite directions. To be acceptable the two runnings of a section must agree within four millimeters times the square root of the distance in kilometers.

The average progress in the work per month is now about 80 miles for each party. The maximum progress ever made by one party was in October, 1914, when 148.3 miles were completed. The rapidity with which leveling is now done is due mainly to the use of the motor velocipede cars as the means of transporting the members of the party and to the more efficient organization and management of the leveling parties.

The great accuracy of the leveling is indicated by the probable error of the elevation at St. Paul, Minnesota (the least accurately known place in the net) resulting from the 1912 general adjustment of the level net of the whole United States, which is only ± 0.005 meter (± 0.21 foot). The average correction to the lines forming the net for loop closure is about 0.15 millimeter per kilometer. An investigation of the small systematic and accidental errors in the precise leveling indicates that, when the ground is sloping, more accurate results are obtained on a cloudy afternoon, with a moderate wind blowing, than under the reverse conditions. When the ground is nearly level, the time of the day and the atmospheric and weather conditions do not seem to have any material systematic effect on the line of levels.

The Engineer Out in the World: MARTIN SCHAEFFER.

The Teaching of Industrial Economics and Management to Engineering Students: HUGO DIEMER.

Recent engineering curricula show that instruction in industrial economics and management is being introduced in an increasing number of institutions. Examples are cited from the curricula of a number of well-known universities and colleges. Statistics regarding the positions held by the membership of the leading national engineering societies show that more than half of the com-

bined membership of these societies consists of men engaged as executives in manufacturing or contracting work. In such work ability as an inventor is less essential than familiarity with principles and applied methods of industrial management.

The speaker outlines the course in industrial engineering given at the Pennsylvania State College.

This course contains all the fundamental mathematics, underlying science and mechanics given in the standard engineering courses, but in place of the more technical work in designing and testing we introduce work in organization, management, theory of accounts, factory accounting, foundry and pattern-shop methods and organization, machine-shop methods and organization, factory lay-out and design and application of such methods of scientific management as planning departments, including orders of work, bulletining, making of time studies, preparation of introduction cards and tool lists, keeping of cost records and accounts on commercial work actually sold, on the one hand, and certain essential exercise work, on the other hand. The degree obtained by students graduating in this course is that of Bachelor of Science in Industrial Engineering.

Methods and New Apparatus for Measuring the Electrical Conductivity above 1500° C. of Vapors at Normal Pressures: EDWIN F. NORTHRUP.

The electrical conduction of gases and vapors at atmospheric pressure at temperatures above 1200° C. have apparently been little investigated quantitatively. If the investigation is to extend to metallic vapors means must be provided for producing and measuring very high temperatures, and if high pressure can be combined with high temperature, a searching experimental method will be provided of ascertaining the true nature of metallic conduction. Some progress is reported in providing the necessary outfit for the investigation of gaseous and vapor conduction at atmospheric pressure and at temperatures up to the melting point of platinum.

A furnace is described which gives safely a temperature above the melting point of platinum and which will maintain a temperature above the melting point of nickel for at least 140 hours. The furnace can then have its life renewed by the introduction of a new heater-unit. A container for the hot gases or metallic vapors is described.

It is shown that the conduction is considerable but complicated in character. It depends (1)

upon the form of the container, (2) probably, upon the material of the container, (3) upon the applied voltage, (4) upon the direction of the applied voltage, (5) upon the temperature, (6) upon the frequency, when an alternating voltage is employed and (7) upon the nature of the gas or vapor.

A description is given of a series of measurements. The data obtained is given, partly in a table and in ten curves.

The considerable conductivity exhibited by a mixture of CO and N above a temperature of 1500° C. suggests the idea that the conductivity found for refractory oxides at and above this temperature is due in considerable part to the hot gases which fill the interstices of the material. This idea was put to the test of experiment and it was found that, under identical conditions in respect to method of measurement, cross section and length of material, etc., at the temperature of 1530° C. through pure aluminum oxide 36 milliamperes and through a mixture of CO + N 8.5 milliamperes passed, the pressure being 50 volts. Hence it is concluded that approximately 24 per cent. of the conductivity of pure aluminum oxide at this temperature is due to the conductivity of the gases in its pores. It therefore seems safe to make the general statement; *that when the temperature exceeds 1500° C., it is impossible to obtain even approximately good insulation by any means.*

One of the most interesting properties of the conducting power of a very hot gas is the asymmetry of the conduction. In a particular case, at a pressure of 80 volts, 15.5 milliamperes passed from a tungsten wire, axially located, to the walls of a graphite cylinder when this wire was made negative, and 45 milliamperes when this wire was made positive. The temperature in both cases being 1510° C.

The writer states that high-temperature investigation presents innumerable problems, and it is in his judgment the most fruitful field for chemical and physical inquiry which is at this time presented to chemists and physicists.

Saturated Vapor Refrigerating Cycles: J. E. SIBBEL.

The author analyzes the energy conversion in refrigerating cycles conceived to be operated perfectly reversible by a saturated vapor with negative specific heat (steam as a representative).

Accordingly, it is found that the work required to produce a certain amount of refrigeration in

such a cycle is greater than in a refrigerating cycle operated reversibly by dry vapor of the same medium.

In the latter case the relation between the work W and the produced refrigeration Q is expressible by the equation

$$W = \frac{Q(t - t_s)}{T},$$

while in the former it must be expressed by the formula

$$W = \frac{(Q + Q_s)(t - t_s)}{T},$$

Q , representing the amount of heat which is to be withdrawn in the compression stage to keep the vapor saturated in a cycle operated between the temperatures t_s and t , T representing the temperature t in absolute degrees.

The Moment of Inertia in Engineering: D. J. MCADAM.

1. Moment of inertia is so important in engineering that its mechanical meaning ought to be well understood and clearly defined.

2. Standard works on mechanics for engineers and mechanics of engineering show that they lose sight of the mechanical effect which it represents and define it and use it as "a name given to a quantity much used by engineers"; and some engineers ridicule radius of gyration as "not being a radius and having nothing to do with gyration."

3. The source of the difficulty in the minds of the users of moment of inertia is: (a) Dread of calling inertia a force. (b) Failure to see that one of the factors in the square of the arm in the moment is a reducing factor.

4. The ordinary definition of moment of inertia is a secondary statement. It is simply a statement of the result of an algebraic multiplication in form of an algebraic formula; or it is a statement of the method of getting that algebraic formula.

5. The true definition of moment of inertia must define it as the moment of forces just as truly as any other moment of forces. And it must state the unit of force or acceleration in which the forces are expressed.

6. *Definitions.*—(a) The moment of inertia of a particle with reference to a point is the moment of the force, which acting upon the particle constantly at right angles to the line joining the particle to the point and acting constantly in the same plane, will produce radian acceleration.

(b) The moment of inertia of a beam at a section is the sum of the moments of the forces which are acting on the various elements of the section when the outer elements are stressed, so that there is unit stress at unit distance from the neutral axis.

7. It is to be observed that in (a) the unit force is one producing unit acceleration, and in (b) the unit force is unit intensity at unit's distance from the neutral axis. Both are forces, however, expressed in terms of a unit force.

8. In the expression for the moment of inertia of a mass about an axis parallel to the axis through its center of gravity, the term to be added to the moment of inertia of the body about the axis through its center of gravity is the moment of the force which will have to be applied to the mass at its center of gravity to cause it to have radian acceleration. This we find to be $FR = MR^2$.

The Use of Electricity in the Manufacture of Portland Cement: MALCOLM McLAREN.

Motors were first used in cement manufacture for driving light machinery in the outlying portions of the mill. As the mills increased in size the use of motors became more general, until now in many cases the entire mill is operated by electric power.

A method is given for determining whether, in an existing mill using steam engines for driving the machinery, it would be advisable to adopt electric drive. It is shown that the mill output should be increased by the change, but that the greatest saving in operating costs would be due to the fact that the steam economy of the steam turbines used with electric drive should be much greater than that of the engines they would replace.

Considering the question of whether the cement company should generate its power or purchase this from a supply company, it is shown that the cost of power per unit depends largely on the amount of power developed. A large supply system, therefore, which carries the combined load of many customers, should be able to produce power at a lower rate than could be done by any of the smaller constituent companies.

Various Engineering Problems in Connection with the Hydro-Electric Plant of the Housatonic Power Company at Bulls Bridge, Connecticut: CHARLES RUFUS HARTZ.

Latent Developments in Marine Electrical Engineering: H. A. HORNOR.

This paper gives a brief review of progress in the development of marine electrical installations. It emphasizes the importance of electric steering, anchor windlass and other recent requirements. The possibilities of under-water communication are considered and improvements in searchlight projectors recorded. The essential points in connection with the introduction of electric propulsion and the opening field of possibilities not only in the design of efficient electrical apparatus but also in the effect upon the art of naval architecture are concisely stated.

The Nolachuckey Hydro-Electric Plant of the Tennessee Eastern Electric Company: W. V. N. POWELSON.

The Location and Maintenance of Railroads and Highways along Steep Slopes: WALTER LORING WEBB.

The paper describes the development of a new principle of construction, when it is necessary to place the roadbed of a railroad or a highway along a slope which already is so steep that any increase in the rate of the slope, made by forming the side slopes above or below the roadbed, causes frequent slides. The usual practise has been to construct retaining walls on the upper or the lower side of the roadbed (or perhaps on both sides) which are necessarily expensive, since they must always sustain a great weight of earth. The method described utilizes the skeleton construction permissible by reinforced concrete and reduces to a minimum the stresses which must be sustained by the structure. An illustrated example of the application of this principle, as developed by the writer in Oil City, Pa., is given in detail. Another illustration of the same fundamental principle, as recently described in the technical press, is also given.

Construction of the New Double Track Tunnel of the B. & O. E. R. through Alleghany Mountains at Sand Patch, Pennsylvania: PAUL DIDIER.

Reconstruction of Bridge No. 100, Pittsburgh Division: J. C. BLAND AND JOHN MILLER.

This bridge, situated a little west of Coshocton, O., was partially destroyed by flood in March, 1913, and the wrecked spans temporarily replaced by girder spans.

The structure, before the flood, consisted of four double tracks through pin-connected truss spans, each 152 ft. 2 in. c. to c. end pins, and was replaced by three double track, through riveted truss spans, each 240 ft. c. to c. end pins. The

total shipped weight of the three spans was 2,740 tons.

The old masonry was replaced by new concrete piers and abutments, the foundations for these being sunk by pneumatic caissons. This new masonry was built by the Foundation Co., of New York.

The new bridge was erected on falsework on the downstream side of the old, and when completed, was used as a run-around to carry traffic while the old structure was being dismantled. The new spans were then rolled into position.

Both the weight moved, 3,250 tons, and the distance moved through, 44 ft. 9 in., constitute a record for an operation of this nature.

The new steelwork was manufactured by the American Bridge Co., of New York, and was erected by the Seaboard Construction Co.

The bridge was designed by Mr. J. C. Bland, engineer of bridges, Penna. Lines West of Pittsburgh, under whose supervision the erection also was carried out.

A Balanced Cantilever Bridge: HENRY H. QUIMBY.

A bridge of a new type was recently constructed at Chester, Pa. It consists of two independently acting parts, each being a double cantilever of ten longitudinal ribs of reinforced concrete resting on a pier over which it is balanced with a counterweight, the channel ends of the cantilevers being connected by a short so-called suspended span, and the whole forming in appearance a concrete arch.

The type was devised as the most economical method of securing an ornamental arch bridge which was desired at this point by the public authorities for esthetic considerations, the subsurface conditions making a real arch very expensive. These conditions consisted of deep soft mud on one side of the river underlaid with a bed of rock sloping steeply away from the channel to a considerable distance and depth, affording no natural skowback for an arch to thrust against.

The pier on the deep mud side is on wooden pile foundations with concrete capping, lateral stability being obtained by surrounding the pier with spur or batter piles.

The bridge is one hundred and sixty feet long over all, with the main span ninety-five feet centers of piers, and the wings thirty-one and thirty-four feet, respectively. It is sixty feet wide, with cartway thirty-six feet between curbs.

The action of the double cantilever is that of the double overhanging gantry crane, the dead load balanced with equal moments over the middle

of each supporting pier, and the traveling live load shifting the center of combined load forth and back over the middle within a range not exceeding one third of the width of the pier, so that tension is never developed at the edge of the bearing.

An open joint was made at one end of the suspended span to provide for temperature movements as well as to keep the cantilevers independent of each other, but the pressure of the earth fill against the ends of the bridge keeps the joint in contact and makes the bridge a real arch to the extent of that pressure, and giving it, under ordinary loads, all the rigidity of an arch.

The Newark Terminal: MARTIN SCHREIBER.
Cooperation between the Physicist and the Engineer: CARL HERING.

Defining engineering as "applied physics," and stating that the province of the physicist is to discover and formulate the laws of nature, while that of the engineer is to then apply these laws and data to the construction of useful structures—the author urges a closer cooperation between them, and shows how much the work of the engineer is dependent upon that of the physicist.

As illustrations of its importance he cites cases in which engineering structures failed due to incomplete statements of the laws of nature in books on physics; or in which in applying the physicist's laws it was found by the engineer that they were faultily stated, resulting in misleading or even wrong results. In other cases the engineer discovered new laws which it was the province of the physicist to have given him, the physicist being better equipped and trained for such research than the engineer.

The physicist taught nothing at all in his books about any internal forces in conductors due to the electric currents flowing through them, yet the engineer in his constructive work found them to exist. Maxwell's famous law of induction, as stated by the physicist, when applied to a specific case gave results which were contrary to the facts, as was found in the constructive work of the engineer. Physics says nothing about axial electromagnetic forces in conductors, yet the engineer finds them to exist. The physicist's work is the foundation of the structure of the engineer, and with an insecure or doubtful foundation, the structure is not dependable. Much time, money and failure can be saved to the engineer if the physicist gives him all the necessary data and states the laws of nature correctly and completely.

Attention is called to cases in which quantitative laws of certain physical phenomenon have not yet been established by the physicist. Overlooking the distinction between the physical and chemical parts of thermo-chemical processes is criticized.

Concerning units for measuring physical quantities, it is shown that the physicist is far ahead of the engineer and the latter would often save himself much work in his calculations by adopting decimal multiples of the absolute units, as was done in the case of the electrical units in which all the conversion factors are made unity by definition. Useless double units should be eliminated, but for some cases double units are advocated for eliminating the factor π from many calculations. In creating new units, physicists are urged to base them on the absolute system, to avoid the use of conversion factors. The physicist's unit of "brightness" of light is criticized as a physical inconsistency and as being an unnecessary double unit.

Numerous references are given to articles in which the topics touched upon are discussed more in detail. The author hopes that his illustrations will show the importance and the benefits of a closer cooperation between the physicist and the engineer.

The fourth session was held on the afternoon of Thursday, December 31, Mr. O. P. Hood in the chair, with an attendance of about 35. The program of the session was as follows:

Some Engineering Achievements in Philadelphia and Environs: EDGAR MARRUBO.

The Hydraulic Laboratory of the Civil Engineering Department, University of Pennsylvania—Its Equipment and Operation: WILLIAM EASBY, JR.
Some Laboratory Accessories for Materials Testing: H. C. BERRY.

Correct Methods of Creating and Maintaining Channels at the Mouths of Fluvial and Tidal Rivers, and at the Outlets of Inclosed Tidal Areas: ELMER COETHELL.

The Engineers' Interest in Deep Waterways with Special Reference to Mississippi River and its Tributaries: HARRY E. WAGNER.

The Tide Water Outlet of the New York State Barge Canals: D. A. WATT.

This paper presents a brief sketch of the work now being constructed by the federal government at Troy, N. Y., in order to provide a connection between tide water in the Hudson River and the

extensive system of state canals, known as the barge canal, now nearing completion by the state of New York. These new canals will provide a modern waterway, not less than 12 feet in depth, between the seaport of New York and the Great Lakes, with a spur running northward along the Hudson Valley to Lake Champlain. The work is practically a reconstruction of the existing system of canals, which have a depth of only 6 feet, but which, nevertheless, constitute an influential factor upon the freight rates of a considerable portion of the United States.

The works which will form the outlet at Troy of this great system will consist of a lock with two tandem chambers, which together will have an effective horizontal area of more than twelve times the area of the present single locks, and the dam will have a length of nearly a quarter of a mile. In addition to these works, between 20 and 30 miles of river channel have to be deepened an average of 3 to 4 feet, so as to provide the channel depth of 12 feet.

The American Bridge Company School Work at Ambridge: J. E. BANKS.

Some Features of the Engineering Plant for the New Agricultural School near Farmingdale, New York: RALPH C. TAGGART.

The Human Nature Element of Engineering Construction with Particular Application to Tropical Situations: T. HOWARD BARNES.

The Dome of the Columbia University Library: O. W. NORCROSS.

The Inspection Department in Its Relation to the Management of Manufacturing Organizations: FRED. B. COREY.

In this paper the author calls attention to the disadvantages inherent in the usual plan of factory organization, in which the inspection department is under control of the works superintendent, and to the great advantages to be gained by placing this department under authority of an executive reporting directly to the general manager, or other officer in control of the factory output.

The executive head of the inspection department should be thoroughly familiar with general engineering practice and standards. He should be well informed in all shop methods, including foundry and machine-shop practice, and be thoroughly versed in the use of testing machines and gages. He should, if possible, be conversant with chemical laboratory methods and apparatus, so as

to be able intelligently to direct that part of his organization. Moreover, he should be familiar with the uses of the factory products and the conditions under which it is to operate after it has passed beyond control of the factory. He must have absolute control of every inspector in the plant and be held responsible for the quality of material and workmanship of all that the plant produces.

The relations that should exist between the inspection department and the sales and engineering departments are quite fully outlined. The inspection department, if rightly conducted, acts for the mutual protection of the manufacturer and the customer and can be of great assistance to the sales department in various ways. At the same time it should maintain the closest possible relations to the engineering department and plans are outlined by which practical cooperation may be secured.

Detail methods of inspection must be suited to the special conditions of each case. It is obviously absurd to try to apply big-shop methods to a small shop, and the converse application, while far more usual, is no more logical. Such matters must, therefore, be subjects of careful investigation and study in each individual plant.

The Application of Science to Telephone Engineering: GEORGE S. MACOMBER.

Reinforced Concrete as an Emergency Repair for Iron Chimneys: A. L. PIERCE.

Mining Engineering Problems Incident to the Development of the South African Diamond Mines: GARDNER F. WILLIAMS.

Shaft Sinking in Excessively Hard Rock: WILLIAM YOUNG WESTERVILT.

The Refrigerating Plant at the Washington Market, New York City: CHARLES H. HIGGINS.

Removal of Henderson Point at the Portsmouth Navy Yard: O. W. NORCROSS.

New Machine for Ginning and Cleaning Cotton: GEORGE T. BURTON.

Spiral Wrappings with Special Reference to Flat Spiral Springs and Stresses in Steel: B. SPENCER GREENFIELD.

At the conclusion of the session an inspection of the new engineering laboratories of the University of Pennsylvania was made under the direction of Professors Edgar Marburg, William Esby, Jr. and H. C. Berry.

THE ELECTRICAL PHOTOMETRY OF STARS¹

In measures of the light of stars there are some advantages and some drawbacks as compared with photometric work in the laboratory. First of all, we are not concerned with absolute measures of intensity, but what we want to know is how the light of a heavenly body varies. If the light is constant, there is not much to be learned, but if it changes, we may infer a great deal from the law of variation. In laboratory and commercial photometry, it is customary to measure what may be called the visual brightness of a source of light, but with the stars it is immaterial for many purposes whether we study the changes of the red, or the blue, or any other part of the spectrum, though in fact any complete stellar photometry should include measures in all regions, infra-red, visible and ultra-violet.

The chief disadvantage in stellar photometry is that the stars are so faint that it is usually not feasible to expand their images out into surfaces, and most forms of stellar photometer depend upon comparisons of two point images by the eye. Although the eye is a wonderful instrument, especially in the range of intensity over which it may be used, the limit of accuracy attained by looking first at one light and then at another is much the same as though instead of using a balance we should weigh objects by lifting them in our hands. It is safe to say that no observer has ever been able to get visual results accurate to 1 per cent., and in the best measures there are occasional errors of 10 per cent., 20 per cent. and even more. It was hoped that the introduc-

¹ Read at the meeting of the National Academy of Sciences, April 20, 1915.

tion of photography would bring greater accuracy in stellar photometry, but at present the errors of the best photographic measures and the best visual ones are about the same.

The use of the property of selenium as a basis of some form of photometer has been made by various investigators, but not many have tried it on faint objects. The principle of converting a light effect into an electrical one is quite simple, for what we call a selenium cell is a bridge or resistance. Light from a bright source like the sun, falling upon a selenium element of 1,000,000 ohms, will reduce the resistance to say 20,000 ohms or one fiftieth of the original. For faint lights there are some special electrical connections which give the best arrangement, but let it suffice to state that as used with our telescope a selenium cell is connected as one arm of a Wheatstone bridge, that we use a d'Arsonval galvanometer, and current is supplied by a few dry cells.

The nature of the problem becomes apparent when we state that the image of a second magnitude star, say the Pole Star, near the focus of a 12-inch telescope objective gives the same surface illumination on a selenium cell that would come from a candle at 150 meters' distance, without any intervening lens. Therefore, to measure the light of such a star with a probable error of 1 per cent. is equivalent to the detection of a candle at 1,500 meters, or roughly a mile. In theory, to work with faint lights we might increase the voltage and use a very sensitive galvanometer, but unfortunately selenium is not so uniform in its action that the sensitiveness of an apparatus can be increased without limit, and the peculiar irregularities of behavior have prevented selenium from being of wider application. It is especially susceptible to temperature changes, and after exposure to

light requires considerable time for recovery. It becomes more sensitive and extraordinarily more regular with decrease of temperature, and conditions are probably best when a cell can be maintained at a uniform temperature of about -20 degrees Centigrade.

We have found it best to keep an ice pack about the cell at the end of the telescope for work in moderate or warm weather, and the whole apparatus is wrapped up in a blanket. The observer, looking through the eyepiece which receives a portion of the light from a star, makes the exposures while a recorder in another room reads the galvanometer. As this second room may be heated, it is our custom, especially in winter, to reverse astronomical practise by having the chief observer write down the notes, while the assistant is sent up into the cold dome to manipulate the telescope.

There is another device, however, which bids fair to supplant entirely the selenium photometer, namely, the photo-electric cell made from one of the alkali metals. The sensitive metallic surface is in an exhausted tube with a small quantity of inert gas, and the effect of light is to release electrons from the surface, which ionize the gas, and thus a current is produced. We are fortunate in having several of our physicists at Illinois interested in photo-electric cells, especially Professor Jacob Kunz, and it is in the laboratory where the really important improvements are made. Only recently we managed to produce a cell which is twice as sensitive as anything we had before, and this amounts to the same thing as though some good fairy had suddenly doubled the light gathering power of our telescope. The great advantages of the photo-electric cell over selenium are first the freedom from irregularities, and next the very short time of recovery. It is too

soon to estimate the relative sensibility but at least a tenfold improvement over the best obtained with selenium is expected with the new apparatus.

We may now consider some of the more strictly astronomical features of the work, and the results to be mentioned were all secured with the selenium photometer. There is one star in the sky which for a hundred years has aroused more interest than any other, namely, the well-known variable, *Algol*. Once in 69 hours the star is found to lose two thirds of its light, due to the eclipse of the main body by a large and relatively faint companion. This principal eclipse has been known and studied for a century, but it has often been pointed out that if the eclipse theory is true then, unless the companion is entirely dark, there should be a second eclipse when it passes behind the main body. This decrease in light midway between the primary eclipses was sought for in vain by visual observers, but observations with the selenium photometer established the presence of a diminution amounting to 6 per cent. There is also a continuous variation between minima, showing that the companion is brighter on the side toward the primary, partly because of reflection, but chiefly because of the heating effect. As the brighter body gives off more than 200 times as much light as the sun, it is easy to show that on the surface of the companion nearest the primary there is received more radiation per unit area than is emitted by the sun, and even on its fainter side, this body, which has often been called dark, has much more than the solar intensity. The scale of miles is not exactly known, but each body has slightly more than the solar diameter, the companion being a trifle larger, and the distance between centers is less than five times the average radius of the spheres.

Another case is the second magnitude

star, *β Aurigæ*, which was one of the first of the so-called spectroscopic binaries to be discovered. As the spectrum lines are single and then double on successive nights, we have a system of two bodies with a period of revolution of about four days. The bodies will be in conjunction as seen from the earth when the spectrum lines are single, and this is the time to look for eclipses. The photometric observations show that exactly at the predicted times the light of the system decreases 7 per cent., the eclipses following each other at intervals of half the period. We have then a twin system, each component having 2.6 times the diameter of the sun, 2.4 times the mass, and being $1/7$ as dense. The surface brightness of each body is at least 12, and possibly 25 times that of the sun, the total light of the system being 150 to 300 times the solar light. Therefore the sun if placed beside these dazzling objects would look like an insignificant dark body.

The next star which has been observed is *δ Orionis*, the right hand one of the three in the Belt of Orion. This object has given us a great deal of trouble, and we have spent something like two hundred hours at the telescope in an effort to smooth out some of the irregularities in the light curve. There are two eclipses, one of 8 and the other of 7 per cent., showing that the companion is nearly as intense as the primary. There is also a variation due to the ellipticity of the orbit, the two bodies being brighter when they are nearer together as a result of a tidal or heating effect. The larger body must have 5 times and probably does have 15 times the solar diameter, while the companion is of half the linear size of the primary. The total mass of the system may be 20 times the sun's, and we can say definitely that the mean density of the system is 0.006 on the solar standard, that is, the bodies average only 6 times as

dense as air. A fair estimate of the total light is that it is equal to 5,000 suns.

These three stars, *Algol*, β *Aurigæ* and δ *Orionis* represent three types of eclipsing binary. The first has a large faint companion, in the second there are twin components, while in the last case the bodies are unequal in size but nearly equal in intensity. As these were actually the first three stars studied with the selenium photometer, and something new came out of each, it is evident that there is plenty of work to be done on similar objects of which there are thousands in the sky. There are at least two other variables which we have picked up, α *Coronæ Borealis*, and the bright star *Spica*.

In fact the large proportion of stars which are variable brings up a number of questions. We may study a large number of stars and find a certain number of eclipsing variables. The proportion of variables gives the probability of such discoveries in a further search, but also we can say that for every variable found there are a definite number of other binary systems the planes of whose orbits are inclined so that we miss the eclipses altogether. From considerations of this nature, it has been possible to conclude: The preponderant type of close binary with components of the same order of size, and of equal or unequal brightness, consists of bodies whose distance between centers is approximately 5 times their average radius, whose period of revolution is about 4 days, and whose mean density is 1/20 that of the sun. Systems of greater or less relative separation are not so numerous, or we should find more of them among the eclipsing variables. This particular discussion is based upon the variables which have been found by visual and photographic methods, but there is abundant field for work in the same line for the electrical photometers. The point to em-

phasize is that not only will systematic studies of stars which vary in light give us direct information, but indirectly we can draw far reaching conclusions about stars which are apparently constant.

Of the many other problems in photometry which may be attacked with good prospect of success may be mentioned the case of our sun, which, according to Abbot, is a variable star. There can not be the slightest doubt of the variation, for a single sunspot is enough to change the total light, the only question is how much? However, the changes in the light are probably measures of the general activity of the sun, rather than of local disturbances like spots. In direct measures of the sun's radiation the chief difficulty lies in the proper allowance for the absorption of the earth's atmosphere, but this trouble may be eliminated by comparing the reflected solar light from one of the planets with the light of a number of stars. Probably Saturn is a good object for this purpose, as there are few markings on its surface, but Uranus would be still better on account of its slower motion, and the greater number of comparison stars which could be found for it.

In the present paper, an attempt has been made to indicate in a general way the work we are doing, and evidently there is considerable variety in it. The production of a good electric cell, and its proper installation in a photometer is a problem in experimental physics, and any success which has come has been through the efforts of several men of widely different training and interests. In the experiments with selenium I had the collaboration of Dr. F. C. Brown, and now, with photo-electric cells, Professor Jacob Kunz is doing his best to perfect our methods. By combining our knowledge and experience we have been able to carry on researches which would have been hopeless for one man

alone. And so it seems to me that a report on such joint work is peculiarly fitting before this academy, which I assume, if it stands for anything, stands for cooperation and mutual help among men of science.

JOEL STEBBINS

UNIVERSITY OF ILLINOIS OBSERVATORY

MR. EDISON'S SERVICE FOR SCIENCE¹

ALL the world is indebted to Mr. Edison, but the portion of it that is under special obligation is the educational world, particularly the schools of technology. It is not merely that he has helped them by criticism and constructive suggestion; it is not merely that by financial assistance he has enabled them to carry on scientific investigations in fields that he has cultivated with such remarkable success; but it is mainly because he has himself been for a generation an educational institution of the first rank. As much as any other school he has had a profound influence throughout the country in arousing in the minds of young men some sense of the limitless possibilities of science when devoted to the service of man and some appreciation of the conditions under which great problems of industrial improvement must be attacked if lasting victories are to be won. It has been a great thing for America to have such a central figure in this age of applied science—a man with such a hold on the popular imagination as to force men to watch what he is doing, for in studying Edison there can not fail to be revealed something of the underlying forces that mould the world of modern industry.

I have said that Mr. Edison is an institute of technology or a school of applied science. Such an institution, if it be worth anything, stands preeminently for three things: for belief in science and in its powers of service, for understanding and appreciation of the method of science, and in the third place, for faith in the gospel of work.

Edison more than any one else in this coun-

try has taught men to see something of what science can do. It would, of course, be impossible on such an occasion as this to enumerate the accomplishments of a life so rich in great achievements. With such an embarrassment of riches, it is scarcely practicable even to single out a few of his great accomplishments. Many of you are familiar with what he did in the early days by way of improving the duplex and quadruplex systems of telegraphy, you know of his invention of the contact transmitter and his development of the loud-speaking telephone, of his marvelous invention of the phonograph (Edison being the first to make a record that would reproduce sound), you think of his wonderful work in 1878 and later years in developing the incandescent lamp, and you realize that he practically made the whole incandescent system, not only inventing the lamp, but turning his attention to all its adjuncts, improving the dynamos for such work and providing the necessary means for the distribution of power over large areas. You recognize that he laid the foundations for the design of central power stations and that his Pearl Street Station was a landmark in the history of science. His work in this field is truly phenomenal, the three-wire distribution, the system of feeders entering the network of mains at different points, the underground conductor system, the bus system in stations, the innumerable accessories of switches, fuses, meters, etc., that he provided are each achievements that would make the fame of any individual. You appreciate the remarkable character of his later work in developing the apparatus of moving pictures and you agree that what he has done still more recently in perfecting the alkaline storage cell is a splendid example of energy and persistence in attacking a difficult problem. Thinking of all these things, you can not fail to be impressed with two things—the enormous range of his activities and the wonderful simplicity of many of his devices. After all, simplicity of device is always the sign of the master, whether in science or in art. In studying Edison you have something of the same impression as in studying Newton

¹ Address at the Civic Forum, New York, May 6, 1915, on the occasion of the presentation of its medal for public service to Mr. Edison.

—you are surprised how easy are the steps. Some one asked Lord Kelvin why no one before Edison had invented so *simple* a thing as the feeder system. "The only reason I can think of," he said, "is that no one else was Edison." As to the range of his activities, he has been associated in some way with so many of the great modern developments that people sometimes speak as if he had invented *everything*, even electricity itself, or if they do not go to this length, they find it necessary to explain why he did not invent this or that. The fact that his name is not intimately associated with one of the great modern achievements—the development of the aeroplane—has called forth numerous ingenious explanations. One of these is that it is due to discouragement resulting from his experience as a boy with an experiment that has often been described. It is said that he induced another boy to swallow large quantities of Seidlitz powders and encouraged him to believe that sufficient gases would be generated to enable him to fly. Whether this be history or fable I know not, but, seeing that he has done so much, we need not spend much time in wondering why he has not done more. Nor need we attempt the impossible in the effort to measure the debt that mankind owes to him. Such statements as have been made to the effect that his inventions have given rise to industries that employ nearly a million of men and thousands of millions of capital really give no adequate sense of the value of his achievements, although they may be of some use as a very rough indication of the scale of his activities.

Not only has he shown his faith in science by great achievements, but he has proved himself a great force in education by giving so brilliant an exhibition of the *method* of science, the method of experimentation. When we get to the root of the matter we see that nearly all great advances are made by improvements in method. There is no evidence that men are abler in the twentieth century than they were in the Middle Ages, but they have learned a new method. "It was in Boston," said Edison, "that I bought Faraday's works, and appreciated that he was the master

experimenter." It is interesting to think what Edison's appreciation of this fact has meant for the world. His popularity and the place that he holds in the public esteem have forced newspaper men to write so much about him that they have often had to rely upon imagination. It is not surprising, therefore, that there are many current myths regarding Mr. Edison. The popular desire for dramatic contrast suggests that to reach the heights of prosperity and public esteem that he has occupied for long, he must have risen from the depths of poverty and neglect. This is a pure myth, harmless, perhaps, and possibly useful as a spur to ambitious youth. A less innocuous myth is the one that sets him up as a "practical man" in the narrow sense. It is true that he has described himself as "pure practise" in distinction from Mr. Steinmetz whom he has called "pure theory," but this, of course, was a joke. Newspaper men have expanded it so as to make it appear that Edison knows nothing about science, cares nothing for the achievements of the great experimenters and thinkers who have preceded him, and merely tries everything that he can think of until he happens upon what he is seeking. Few things more absurd could be suggested. He is no slave to theory; he is ready, as every scientific man is ready, to try anything that seems reasonable, but practically always he has what seems to him a good reason for everything that he tries. In the rare cases where he has tried blindly, it has been because there was absolutely no light.

Just one more observation and I am done. His other great contribution to the progress of education has been his constant insistence on the gospel of work. Genius was long ago described as "an infinite capacity for taking pains." We all feel this to be inadequate, and Edison has put the underlying thought more accurately and more picturesquely by his aphorism that "genius is one per cent. inspiration and ninety-nine per cent. perspiration." Contrary to the general notion, very few of his inventions have been the result of sudden inspiration. Practically all have been evolved by slow and gradual processes. His day is

said to be a twenty-four-hour day, and he is always working when there is anything to do. Weeks and months and sometimes years of tedious experimenting, dauntless patience and unflagging industry, have marked his onward march to victory from the beginning until now. His is a splendid example of scientific pertinacity rarely if ever surpassed in the history of human achievement. He has won and held the admiration of the world; and his influence must remain as a permanent source of inspiration both within the schools and without.

RICHARD C. MACLAURIN

MASSACHUSETTS INSTITUTE OF TECHNOLOGY

THE PROCEEDINGS OF THE NATIONAL
ACADEMY AS A MEDIUM OF
PUBLICATION

THE establishment of monthly *Proceedings* by the National Academy of Sciences, in which the first announcements of new advances are made, has met with instant recognition by a wide circle of investigators. Eighty-three original papers have appeared in the first five numbers, and the inflow of manuscripts is continually increasing. Many university departments and several research laboratories, namely, the Rockefeller Medical Institute, the Lick and Yerkes Observatories, the Nutrition, Experimental Evolution, and Marine Biological Laboratories and the Mount Wilson Observatory of the Carnegie Institution, and the Research Laboratories of Harvard University and the Massachusetts Institute of Technology have already indicated their intention of adopting the *Proceedings* as their regular medium for announcing new and important results. The success of the *Proceedings* is therefore amply assured.

The need of a national journal representing the joint interests of science as a whole and providing for the prompt publication and wide distribution of the chief results of American research has been felt in every department of science. The vigorous developments of science in recent years have carried us past the time when all of the special journals could assure early publication; and their very multiplicity has stood in the way of wide foreign

circulation. Four leading American journals of biology have an average paid foreign circulation of 93 copies (maximum 109, minimum 77). This is not due to any inferiority in quality, as all of these journals are of the first rank. Nor does it indicate that they are undesirable places to publish. On the contrary, they have come into existence to meet a natural demand, and they certainly afford the most satisfactory means of publishing extended technical papers, intended for investigators in the fields which they represent. The *Proceedings* are expected to supplement them and should aid materially in increasing their circulation; for authors are requested to adopt the uniform practise of referring in each article to the journal in which the details of their investigations will subsequently appear. Such frequent references, seen by a wide circle of readers, will soon have their effect.

It is in the character and scope of their circulation that the *Proceedings* will perform their best service. Truly national in character, with a membership elected on equal terms from all sections of the country, and serving as the representative of the United States in the International Association of Academies, the National Academy of Sciences is peculiarly fitted to bring its publications to the attention of foreign readers. In Europe the academy is regarded as the natural representative of American research, and this fact gives at once to the *Proceedings* an authoritative standing among foreign investigators.

As foreign secretary of the academy, I have been called upon to prepare, with the cooperation of the editors representing all departments of science, a comprehensive list of foreign exchanges. Every effort has been made to secure a well-balanced distribution. From the extensive data in *Minerva* relating to academies, societies, universities, seminars, general and special libraries, laboratories, observatories, museums, botanical and zoological gardens, biological stations, geological surveys, and other centers of study and research, a representative group of about 900 foreign institutions has been compiled. In preparing this mailing list use has also been made of the ex-

change lists of the Royal Society and other similar bodies. Bibliographical bureaus, year-books and journals giving special attention to abstracts and reviews have been included in the mailing list. Chief stress, however, has been laid on placing the *Proceedings* in the leading research centers, including university departmental libraries when these are of sufficient significance. In many cases it by no means suffices to send the *Proceedings* to a general university library; they must also be readily accessible in the departments and seminars where the work of research is mainly done.

Such a distribution will obviate the necessity, felt by some American investigators, of publishing their papers in foreign journals. They may now secure the circulation they desire by presenting their chief results in the *Proceedings* and the details in an American special journal.

Publication in the *Proceedings* will also have the advantage of bringing researches in one department of science to the attention of scholars in other departments, who would otherwise fail to see them. In a period when many of the greatest advances are being made in the fields lying between the traditional branches of science, and when the wide adaptability of various methods of research is being repeatedly demonstrated, it is unnecessary to dwell upon this point. It may only be mentioned by way of example that a well-known physicist has recently spoken to me of the advantage of seeing in the *Proceedings* short astronomical papers which he would not have opportunity to read in their more extended form.

As readers in widely separated fields may be expected, authors should make their papers as clear and as readable as possible. The papers should open with a statement of the purpose in view and the broader bearing or antecedent conditions of the investigation, and should close with a summary of results. The papers should be short, of two to six pages in length; but they should not be mere abstracts, devoid of interest except as a bare statement of facts, but complete and well-rounded articles, grounding their conclusions upon a substantial basis

of calculations, observations or experiments, though free from all unnecessary technicalities and details and from extensive tabulations of data. They should always appear in the *Proceedings* prior to their publication in special journals.

While serving the purposes already enumerated, the *Proceedings* will attempt also to contribute to the popularization of scientific research. Nothing could be more injurious to the public appreciation of science than its current distortion by the newspapers. Mr. Melville E. Stone, general manager of the Associated Press, feels this no less keenly than the men whose work is so often misrepresented by reporters. He would heartily welcome means of securing reliable statements of progress in science, expressed in clear and unsensational form, for use by the Associated Press. By an arrangement with him the editors of the *Proceedings* will attempt to supply suitable statements, based upon such articles as are of sufficient general interest and importance. Authors who prefer not to have their articles used in this way may notify the editors. Every effort will be made to secure clear and dignified statements, expressed whenever possible in the author's own language. The experiment is not without its difficulties; and success may not be attained at once. It nevertheless seems important to make the attempt, in order to counteract in some measure the present unfortunate condition of affairs.

Provision will also be made for a review of the papers published in the *Proceedings* in the widely circulated journals of general science. Thus such a review will appear regularly in the columns of *SCIENCE*; and an arrangement has been made with the editor of *Nature* for the publication of reports on the monthly issues of the *Proceedings*. The *Scientifica Americana*, which is conducted in a very creditable manner, will also, through an arrangement made with its managing editor, Mr. Waldemar Kaempfert, present accounts of the articles of popular interest.

In closing this paper, in which I have tried to indicate how the *Proceedings* of the National Academy may serve as a prompt and

convenient means of announcing and circulating the chief results of research, I should perhaps add a word to those who have not yet contributed to their pages. Papers are accepted solely on their merits, from non-members as well as from members of the Academy. To facilitate the work of the editors, it is required that papers by non-members be transmitted to the managing editor by a member, but neither the manner of printing nor the sequence of the papers in the *Proceedings* is affected by this fact. Further information may be obtained from Professor A. A. Noyes, chairman of the board of editors, Massachusetts Institute of Technology, Boston.

GEORGE ELLERY HALE

THE SEATTLE MEETING OF THE AMERICAN CHEMICAL SOCIETY

THE vote recently received at the secretary's office being overwhelmingly in favor of the Great Northern Railroad, which stops at Glacier National Park, arrangements have been made with this road for the party to leave Chicago at 5:05 P.M. Thursday, August 26. One and one half days will be spent at Glacier National Park, and Seattle will be reached at 6 P.M. August 30. August 31, September 1 and 2 will be spent at Seattle, and on the evening of September 2 the party will take a special train to Mt. Ranier National Park, where they will remain on Friday, September 3, leaving there that evening and arriving at Portland the following morning; spending the day in Portland as the guests of the Oregon Section; leaving Portland Saturday night, passing through the Mt. Shasta and Mt. Lassen region on Sunday and arriving in San Francisco Sunday evening. At San Francisco the party will break up, returning via any route they choose.

The round-trip rates from Chicago are \$80. The sleeping car rates from Chicago to San Francisco by the route of the special train are as follows: Lower berth, \$22.50; upper berth, \$18.00; compartment, \$63.00; drawing room, \$80.00.

There will be an additional Pullman charge to Mt. Ranier National Park, which will, however, be little if any more than hotel accommodations should the party remain in Seattle.

There may be also a small additional Pullman charge for holding the train at Glacier and Portland. There will be a charge of \$12.50 for 114 miles of automobile trip and 20 miles of launch trip in Glacier National Park, and \$5.00 for the side trip through Tacoma to Mt. Ranier National Park. The hotel rates in Glacier National Park are from \$3.00 to \$5.00 per day on the American plan. Those who wish may spend the night at "Many Glacier Camp" instead of at "Going-to-the-Sun Camp" on the night of August 29, which will give them plenty of time to take a side trip to the wonderful Iceberg Lake on the morning of the 29th.

As the Great Northern passes the very gates of Glacier National Park, a trip through the park is a very simple matter. The tremendous mountain land of Glacier National Park sits high up in the Rocky Mountains of north-western Montana and stretches to the Canadian border. The park is of 1,525 square miles extent, with a veritable army of magnificent peaks rising from 8,000 to 10,000 feet, with their bases thickly timbered and their limestone crests painted in many colors—reds, browns, blues and purples. On the tops of these mountains are 20 glaciers every bit as inspiring as those ice fields which Americans have been crossing to Switzerland to see; of these the great Blackfoot Glacier has an area of five miles. There are more than 250 glacier-fed blue mountain lakes. So well have the most important sections of the park been linked by government auto stage roads that it is now possible to see within a short time what formerly required weeks to visit.

So much has been written about the wonders of Mt. Ranier National Park that there is little need to add detail here. The following quotation from the *Travelers Magazine* will be sufficient: "Read as much about it as you will, see it pictured a thousand times, and believe all the tales you hear of it, and on going there you will find that it has been underrated. It is hard to believe when you see it. Mt. Ranier is the highest mountain in the United States and has a glacial system greater than that of the whole Swiss Alps. The National

Park has an area of somewhat more than 200,000 acres. How bald and uninspiring are statistics! Let it be said, rather, that this is the most beautiful place in the world."

Interesting, illustrated literature may be obtained describing Glacier National Park from H. A. Noble, general passenger agent, Great Northern Railway, St. Paul, Minn., and of Mt. Ranier National Park from the Chicago, Milwaukee & St. Paul Railway, Chicago, Ill., and Seattle, Washington. The following beautifully illustrated publications may be obtained from the superintendent of documents, Washington, D. C., for the price noted:

Some Lakes of Glacier National Park, 10 cents.

Glaciers of Glacier National Park, 15 cents.

Origin of the Scenery Features of the Glacier National Park, 15 cents.

Glacier National Park, with map (Bulletin 600 U. S. Geological Survey), 30 cents.

Mt. Ranier and Its Glaciers, 15 cents.

It is of the utmost importance for the success of this trip that the secretary be informed at the earliest possible moment of the intention of those intending to be present, the accommodations needed and the number of tickets required. In this connection it should be noted that in purchasing tickets free side-trip tickets to the San Diego Exposition from Los Angeles; to Colorado Springs from Denver; to Salt Lake City from Ogden, may be had, by any member of the party returning through these cities if the request for this side trip is made at the time ticket is purchased.

Members of other scientific societies and friends recommended by members of the society will be gladly received on the special train.

CHAS. L. PARSONS,
Secretary

WASHINGTON, D. C.,
Box 505

SCIENTIFIC NOTES AND NEWS

A BANQUET in honor of Dr. William T. Councilman, professor of pathology in the Harvard Medical School and formerly of the Johns Hopkins Medical School, was given in Baltimore, on May 18, by his colleagues and

former students. At the banquet a portrait of Professor Councilman was presented to him.

PROFESSOR R. NEWSTEAD, of the Liverpool School of Tropical Medicine, is in France, prosecuting entomological investigations from the point of view of military sanitation.

PROFESSOR VERNON L. KELLOGG, of Stanford University, sailed for Liverpool on May 26 to join the commission for relief in Belgium. He will spend the summer in volunteer work for the commission.

DR. FRANK G. SPECK, of the department of anthropology of the University of Pennsylvania, is on a leave of absence for his summer's work in the field. He will spend a large part of the summer among the Montagnais and Mistassini Indians, who are tribes of southern Labrador, for the purpose of completing his collection of texts in the native languages of three tribes.

DR. JOHN ULRIC NEF, professor of chemistry and head of the department at the University of Chicago, delivered a lecture on May 21 before the Phi Lambda Upsilon, honorary chemical society of the university. His subject was "The Chemistry of Enzyme Action."

DR. RICHARD M. PEARCE, professor of research medicine at the University of Pennsylvania, addressed on May 21 the Academy of Medicine of Cleveland, his subject being "The Relation of the Spleen to Blood Destruction and Regeneration and to Hemolytic Jaundice." Following the lecture a smoker was given at the University Club in honor of Professor Pearce by the heads of the departments of medicine and of surgery and of the various laboratories of the school of medicine of Western Reserve University.

THE Swarthmore lecture of the Society of Friends, London, was given on May 18, by Professor Silvanus P. Thompson, who spoke on "The Quest for Truth."

IN memory of Dr. Edith J. Claypole, research associate in the department of pathology of the University of California, who died on March 26, 1916, friends of the university have offered an annual gift of \$1,200 to maintain the position of research associate to

pathology, and have made definite provision for an endowment sufficient to yield this income. The immediate purpose of the position is to be a continuance of investigations in which much valuable work has already been accomplished by Dr. Claypole, in collaboration with Dr. F. P. Gay, professor of pathology in the University of California, in regard to improved methods for immunization against typhoid and methods for the treatment of that disease.

THE name of Curie, in honor of the discoverers of radium, has been given to a small park formed by the tearing down of the old rue Dauphine in Paris.

AT commencement at the University of California, honorary degrees were conferred on Chancellor David Starr Jordan and President John Caspar Branner, of Stanford University, and on the Hon. Alfred Deakin, of Melbourne, the first prime minister of the commonwealth of Australia.

AT the recent annual meeting of the Association of American Physicians, held in Washington, Dr. Henry Sewall, Denver, Colo., was elected president, and Dr. George Dock, St. Louis, vice-president.

DR. LLEWELLYS F. BARKER, of the Johns Hopkins Medical School, was elected president of the American Neurological Association at the meeting held recently in New York City.

THERE is exhibited at the Royal Academy this year a portrait of Sir Archibald Geikie, painted by Mr. R. G. Eves for presentation to the Royal Society.

THE Pereira medal of the British Pharmaceutical Society has been awarded to Miss Dora F. White, and its silver and bronze medals to Mr. A. J. Somer and Mr. R. W. Bowles, respectively.

DR. SAMUEL G. DIXON, Philadelphia, whose renomination as Pennsylvania state commissioner of health was sent to the senate by the governor, on May 17, was confirmed on May 18. This is the third reappointment of Dr. Dixon to this position which he has now held for nearly ten years.

DR. ROSCOE W. HALL has succeeded Dr. David K. Henderson as resident physician of the Phipps Clinic of Johns Hopkins Hospital. Dr. Henderson has been appointed superintendent of the Royal Asylum of Scotland, Glasgow.

MR. G. MASSEE has retired from his position as head of the cryptogamic department in the herbarium at the Royal Botanic Gardens, Kew.

A DEPUTATION from the Royal Society and the Chemical Society was received by the presidents of the boards of trade and education on May 6. The deputation was introduced by Sir William Crookes, president of the Royal Society, and Professor W. H. Perkins, Sir William Tilden, Professor P. Frankland, Professor W. J. Pope and Dr. M. O. Forster spoke in support of memorials from the two societies, indicating the steps which might be taken to improve the status and efficiency of the chemical industries and those engaging in them in the United Kingdom.

THE *Irish Naturalist*, as quoted in *Nature*, states that the following naturalists in Ireland are among those who have been given commissions in the army: Professor Gregg Wilson, professor of zoology, and Dr. A. R. Dwyerhouse, lecturer in geology, Queen's University, Belfast; Professor H. A. Cummins, professor of botany and agriculture, University College, Cork; Mr. C. M. Selbie, of the National Museum, Dublin; Mr. G. P. Farran and Mr. A. B. Hillas, of the Fisheries Office; Mr. H. T. Kennedy and Mr. R. L. Valentine, of the Geological Survey.

MR. CHARLES H. MARTIN, of Abergavenny, was killed in the war on May 3 at the age of thirty-three years. He was known for his researches on the protozoa.

ACCORDING to the *Revue Anthropologique*, two noted French pre-historians, Joseph Déchelette and Captain M. Boursin, have died at the front. Déchelette will long be remembered for his great work entitled "*Manuel d'archéologie préhistorique, celtique et gallo-romaine*," of which the first volume appeared in 1908 and the third part of the second and last volume in 1914, only a short while before

the outbreak of the war. Captain Bourlon, an enthusiastic and gifted explorer of the paleolithic French caves, had written a number of valuable papers based on his field work.

LADY HUGGINS, who died on March 24, leaving an estate valued at about \$80,000, made, as we learn from *Nature*, the following bequests, among others: A sum not exceeding £1,000 to the Bedford College for Women (University of London); £500, and, if her estate is sufficient, a further sum of £500 for the erection of a memorial in St. Paul's Cathedral to the memory of her husband; £1,000, and if her estate is sufficient, a further sum of £1,000 to the City of London School, Victoria Embankment, for the endowment of a scholarship for the study of astronomy, tenable at Cambridge, to be called the "Sir William Huggins" Scholarship; and a sum of not more than £300 for finishing, editing and illustrating the book on which she was engaged, being the life of her husband. The residue of the estate, if any, is left to the City of London School.

THE department of physiology of Columbia University had recently on exhibition in the students' reading room at the College of Physicians and Surgeons, some of the books belonging to the valuable medical library of the late Professor John G. Curtis, which has been recently acquired by the department. These books comprise first editions or early copies of the leading classical writers on physiology and medicine, and include Hippocrates, Galen, Rufus of Ephesus, Aretæus, Soranus, Ætius, Rhazes, Haly ben Abbas, Avicenna, Mondino, Vesalius, Cesalpino, Eustachius, Colombo, Bonaciolus, Varolius, Vidius, Wharton, Valsalva, Van Helmont, Mayow, Harvey, Riolan, Malpighi, Leeuwenhoek, Hooke, Swammerdam, Sanctorius, Vieussens, Aselli, de Graaf, Highmore, Brunner, Stensen, Peyer, Huysch, Lieberkühn, Hales, Santorini, Morgagni, Galvani, Lancisi, Whytt, John Hunter and others.

THE Ohio Academy of Science at its annual meeting held recently in Columbus voted to deposit its collection of books, pamphlets, periodicals and other publications of the society in the library of the Ohio State University.

THE American Climatological and Clinical Association will hold its thirty-second annual meeting in San Francisco on June 18 and 19, under the presidency of Dr. Henry Sewall, Denver.

ON June 26 there will be a New York State civil service examination for special assistant in chemistry, Psychiatric Institute, Ward's Island, New York City, at a salary of \$1,200. Candidates will not be required to appear at any place for examination, but will be rated on education, special training, experience and personal qualifications as shown by their sworn statements and by answers to inquiries which the commission may make of their former employers and others acquainted with their experience and qualifications. The duties of this position are that of research assistant in the chemical department of the Psychiatric Institute, and candidates should be able to furnish undisputed evidence of some experience in work in the chemistry of the brain in connection with a research laboratory under the direction of a recognized authority among physiological chemists.

THE *Plant World* announces two prizes which are to be awarded for the best papers embodying original work in any phase of the water relations of plants. The amount of the first prize is \$50, and of the second prize \$10. The offering of these purses is made possible by the generosity of Professor B. E. Livingston and by contributions from Dr. D. T. MacDougal, Professor J. J. Thornber, Dr. J. B. Overton, Dr. H. C. Cowles and Mrs. Edith B. Shreve. Competing papers should be written so as to give no internal evidence of authorship, and should be sent to the editor of the *Plant World* by December 1. The *Plant World* reserves the right to publish any papers submitted in the contest.

DR. STEPHEN SMITH recently received the following resolutions which were passed at the last meeting of the American Public Health Association, held at Jacksonville, Fla., in December:

Resolved, That the American Public Health Association desires to extend to Dr. Stephen Smith,

one of the first organizers of this association in 1872, its congratulations on his continued enjoyment of health and its joy and pleasure in being able to illustrate the outcome of his efforts and those of his colleagues in the present prosperity of the association, which has expanded until it represents the public health interests of four countries and of one hundred and twenty-five million people.

Resolved, That the association wishes Dr. Stephen Smith all of the happiness which the contemplation of a life spent in public service for the amelioration of the sufferings of mankind may bring.

THE St. Lawrence River system is international, and new questions arise almost every year with respect to the proper division of authority over and the use of this great source of water supply. An important report, recently issued by the United States Geological Survey, entitled "Surface Water Supply of St. Lawrence River Basin, 1913" (Water-Supply Paper 354), by C. C. Covert and W. G. Hoyt, contains results of steam-flow measurements made in the St. Lawrence River basin during the year 1913. The report includes measurements on rivers emptying into the St. Lawrence by way of Lake Champlain and the Richelieu in New York and Vermont. The diversion of water for the development of power at Niagara has recently claimed the attention of both the countries interested, and another question quite as important now is that of the propriety of permitting the city of Chicago to divert large volumes of water from Lake Michigan through its drainage canal into Illinois River. By reason of the prospective decrease in the depth of navigable waterways, especially those between Lakes Michigan and Huron, and between Lakes Huron and Erie, protests have been made by the Canadian authorities. The two questions mentioned illustrate the importance of determining accurately the amount of water supplied to the Great Lakes and St. Lawrence system by the tributaries within the United States, because international questions may at any time arise in settling which data of this kind may be of the utmost importance. Water-Supply Paper 354 is the latest of a series of similar annual volumes covering measurements on the

principal streams of the St. Lawrence basin. The work done in Minnesota, New York and Vermont was in cooperation with the state authorities. A copy of the report may be obtained on application to the Director of the U. S. Geological Survey, Washington, D. C.

COLUMBIA UNIVERSITY has appointed the following non-resident lecturers for the 1915-16 session of the graduate course in highway engineering: Charles J. Bennett, state highway commissioner of Connecticut; John A. Benschel, consulting engineer; Will P. Blair, secretary, National Paving Brick Manufacturers' Association; Sumner R. Church, manager, research department, Barrett Manufacturing Company; Frederick A. Cleveland, director, Bureau of Municipal Research, New York; William H. Connell, chief, bureau of highways and street cleaning, Philadelphia; Morris Llewellyn Cooke, director, department of public works, Philadelphia; W. W. Crosby, chief engineer, Maryland Geological and Economic Survey; Charles Henry Davis, president, National Highways Association; A. W. Dow, chemical and consulting paving engineer; Edwin Duffey, commissioner of highways, New York state; Lewis R. Ferguson, assistant secretary, Association of American Portland Cement Manufacturers; C. N. Forrest, chief chemist, the Barber Asphalt Paving Company; Wilson P. Foss, president, the New York Trap Rock Company; Walter H. Fulweiler, chief chemist, the United Gas Improvement Company; E. P. Goodrich, consulting engineer; D. L. Hough, president, the Cuban Engineering and Contracting Company; William A. Howell, engineer of streets and highways, Newark; Nelson P. Lewis, chief engineer, board of estimate and apportionment, New York; Walter R. Marden, vice-president and chief engineer, the United Construction Company; H. B. Pullar, general manager, the Pioneer Asphalt Company; Philip P. Sharples, manager, General Tarvia department, Barrett Manufacturing Company; Francis P. Smith, chemical and consulting paving engineer; Albert Sommer, consulting chemical engineer; George W. Tillson, consulting engineer to the president of the Borough of Brooklyn, New York; John Cassan Wait, attorney at law;

George C. Warren, president, Warren Brothers Company.

UNIVERSITY AND EDUCATIONAL NEWS

DR. LUTHER DANA WATERMAN, of Indianapolis, professor emeritus in the Indiana University School of Medicine, has made a gift to Indiana University amounting to one hundred thousand dollars, subject to an annuity during his life time on the condition that the university appropriate an amount equal to the income from this gift, the entire proceeds to be used for scientific research. The conditions and gift have been accepted by the trustees of the university.

ALBERT BONNHEIM, of Sacramento, has given to the University of California an endowment of \$30,000 with provision for its subsequent increase to \$160,000, the income to be devoted to the maintenance of scholarships.

ANOTHER gift of \$85,000 has been made for the erection of dormitories at Cornell University. This gift comes from the same anonymous contributor of \$250,000 some time ago. Two dormitories under construction are expected to be ready for occupation by September 1.

DR. HENRY ALBERT MATTILL, who recently resigned his chair in the University of Utah, has been appointed assistant professor of nutrition in the University of California.

J. BROWNLIE DAVIDSON, of Iowa Agricultural College, has been called to the University of California to fill a newly established professorship of agricultural engineering. His special work is to be to develop at the University Farm at Davis a testing plant for investigation of the fundamental reasons for efficiency of farm machinery.

HOWARD SPENCER REED, now professor of plant pathology and bacteriology in the Virginia Polytechnic Institute, has been appointed professor of plant physiology in the Citrus Experiment Station and Graduate School of Tropical Agriculture, recently established by the University of California at Riverside, California.

THE following appointments and promotions in the Stanford University Medical School

have been made for the year 1915-16: Dr. Charles Harvey Bailey, formerly connected with the Crocker Research Laboratory, New York City, has been made assistant professor of pathology. Dr. Henry Augustus Stephenson, formerly assistant in obstetrics and gynecology in the Johns Hopkins Medical School, has been made assistant professor of obstetrics and gynecology. Dr. George De Forest Barnett (M.D., Stanford, '13) and Dr. Jean Redman Oliver (M.D., Stanford, '14) have been made instructor in medicine and instructor in pathology, respectively.

THE following appointments were made at the last meeting of the executive committee of the Massachusetts Institute of Technology, the resignations of E. H. Magoon, assistant in civil engineering and Thomas Buel, research assistant in electrical engineering, being accepted. Dr. Barnum B. Libby and George Rutledge, instructors in mathematics; Clark S. Robinson and Clifton N. Jacobs, instructors in inorganic chemistry; Francis C. Atwood and Roscoe G. Dickinson, assistants in theoretical chemistry; John N. Dalton, assistant in organic chemistry; Charles H. Rosenthal, Robert V. Townsend and Donald A. White, research assistants in applied chemistry, and R. J. Wiseman and Albert C. Brown, research assistants in electrical engineering.

DR. CORNELIUS BETTEN has resigned the professorship of biology in Lake Forest College to become secretary of the College of Agriculture in Cornell University.

HOWARD B. LEWIS, Ph.D., instructor in physiological chemistry at the University of Pennsylvania, has been appointed an associate professor in the University of Illinois.

MESSERS. F. T. BROOKS, Emmanuel College, and R. H. Compton, Gonville and Caius College, have been appointed demonstrators of botany at Cambridge.

DR. J. SHOLTO C. DOUGLAS, lecturer on pathology in the University of Manchester, has been appointed to the Joseph Hunter chair of pathology in the University of Sheffield in succession to Professor Dean.

DISCUSSION AND CORRESPONDENCE

BIRD COLLECTING AND ORNITHOLOGY

THE letter from Mr. Joseph Grinnell published in *SCIENCE* for February 12 last, in which he pleads for the conservation of the old-fashioned bird collector has led the present writer to suggest a few points on the other side of the question. The menace to our laws protecting birds and to our system of government bird reservations contained in Mr. Grinnell's attacks on them does not seem serious, nor does anything in his letter appear likely to greatly affect the opinion now prevailing not only among the general public, but among scientific men, that even a much more complete disappearance of such bird collectors can be contemplated without anxiety for the future of science in general and of ornithology in particular; that the usefulness of such collectors except in remote and little explored regions has largely gone by; that their assistance to real science is rarely more than very slight and oftener nothing at all; and that their destructiveness is very great. Too many of Mr. Grinnell's claims are directly opposed by the results of practical experience. For instance, who can deny that many holders of permits for collecting birds for scientific purposes are using them for commercial collecting, and that many of those who are making bird collections either with or without such permits encourage violations of the law by others through buying specimens from those who have no right to kill or sell them? Yet Mr. Grinnell would have us break down all restrictions, and have collecting permits "issued by both state and federal governments freely to applicants upon avowed sincerity of purpose."

Neither does Mr. Grinnell's claim that sportsmen are more liberally treated than those claiming to have scientific purposes in view require discussion here. The rapid decrease of our game birds indicates the need of better control of the sportsmen, but not necessarily the removal of restrictions from others.

On the other hand, there are many questions raised in or suggested by this letter that are timely and deserve serious consideration, and it is to some of these that the writer in-

tends to confine his communication. Are any real scientific investigations, even of very minor importance and doubtful value, being prevented or hindered by existing restrictions on collecting? If so, can Mr. Grinnell name them? Has not systematic ornithology, that is the distinguishing and describing of new species, subspecies and races, proceeded to such a point in nearly all parts of North America that material is now needed as a basis for any reliable conclusions in amount far beyond what even the most capable amateur can accumulate, even if unrestricted in his collecting? Are not the large collections of the National Museum and other public and semi-public institutions made partly for just that kind of study, and is not the help of such institutions liberally given to those who desire it?

The writer will not maintain that there are not still many restricted and special problems in systematic ornithology even in the United States, which independent study can effectively deal with. Is there any would-be investigator having a definite problem of that kind to settle that finds his purpose blocked by the refusal to permit him to collect the limited and special material necessary for his needs?

The scientific value of the average bird collection, or even of one made with far more than average care, is greatly overrated. As a rule the collector publishes little or nothing in regard to his studies, if indeed he does study his specimens at all. If he happens to be a wealthy man he may acquire large series of birds and eggs, entailing great destruction of bird life and disastrous effects on some of our rare and disappearing species; but when he tires of his fad, or when his collection comes into the possession of his heirs, it is not unlikely to perish from dust, moths and careless keeping, or, if eventually donated or sold to some public or educational institution, to reach the latter in a condition where most of its scientific value has been lost. Amateur collectors frequently fail to preserve those notes and data by which they might fill the gaps in our scientific knowledge and the deficiencies in the descriptions in our scientific

books, because they do not know enough to do so, or are too careless or too hurried in their endeavors to get large series of specimens. The source, localities and dates of the specimens in such collections are often doubtful, since the collectors are likely to be careless in distinguishing between reliable first-hand information and that which somebody tells them, and too ready to accept as truth and to record as facts statements of unscrupulous dealers in regard to the specimens they sell; and the existence of material scattered in small collections is generally unknown to those who might employ it to advantage in the investigations they are conducting. The number, cheapness and general accessibility of reliable books on birds, many of them with photographs from life and colored illustrations of a high degree of accuracy, has greatly detracted from the educational importance of bird collections, not only for the general public, but for those wishing more than a superficial acquaintance with our birds.

If annoying restrictions are in some places imposed on scientific ornithologists, is it not largely because they have too often allied themselves with those who collect birds and eggs merely as a hobby, and who might better be engaged in the less destructive pursuit of collecting postage stamps? No doubt this alliance has been partly for the sake of increased opportunities for obtaining specimens by purchase or exchange, and partly because of a belief that some ornithological genius might develop among the amateurs thus incited to greater efforts. But has not the actual result been to lower the character of bird study—to place ornithology in a position apart from other branches of zoology and nearer to pursuits not truly scientific?

It has resulted in spreading altogether mistaken ideas of what science is and of what ornithology should be, and encouraged such false and destructive delusions as the common idea that one of the highest achievements of the ornithologist is to kill some rare straggler or accidental visitor and "establish a record" or "add to the fauna" of his state or county some species not previously listed, which, from any common sense point of view does not prop-

erly belong to the fauna at all. If such rare bird visitors are of species formerly found in the region but now practically or entirely exterminated, their killing may effectually put an end to an attempt to reoccupy the abandoned territory, and thus prevent the species being added to the fauna in reality, not merely in ornithologist's language. The writer thinks that many ornithologists and other scientific men who believed in their younger days that it was a necessary incident, if not the largest element, in being an ornithologist, to go out and shoot catbirds, scarlet tanagers and bluebirds, and rob their nests, have now discovered that they did so because they did not know any better, or followed bad advice given by other collectors or contained in the older manuals for ornithologists. Most of them will certainly be inclined to suspect that they could have learned many times as much about birds in less destructive ways, and probably few of them would in that case have found bird study any less interesting. More is being discovered about birds to-day with field glasses and cameras than with gunpowder and shot, and much of it is trustworthy scientific information, which to say the least ranks as high in interest and value to humanity as that which the average bird collector's cabinet of bird skins and egg shells can afford.

In closing the writer would like to emphasize the fact that this is no time for reactionary protests and attacks on the tardy and insufficient efforts that are at last being made to save our native birds and animals from extinction. The indifference displayed by scientific men to the destruction that has been and is still being carried out in every part of the world is far from creditable, since in many cases they are the only ones who realize its extent and inevitable results, and who can bring the subject to the attention of the public and intelligently plan and direct methods to stop it. The list of North American birds already destined to extinction within the next few years is considerable. Only very prompt action will save a good many others whose preservation is not yet hopeless.

The large whales and certain other marine mammals, a considerable proportion of the

larger land mammals of the world, and the peculiar and interesting indigenous faunas of many small islands may still be permanently preserved by prompt protective measures, and not merely state and national action, but as soon as the war is over, international agreements to bring about cooperation for these ends are urgently needed. Future generations will look back on the present time as an age of shameful vandalism as far as nature is concerned. Our present imperfect and feebly carried out efforts for the preservation of the most interesting and wonderful of the birds and mammals that still survive are insufficient. They must be on a larger scale and more effectively and intelligently conducted than at present. It should be the effort of every scientific man, and especially of the larger and more influential scientific associations, to bring the seriousness of the situation to public notice and to insist on prompt action. This is vastly more important for zoology to-day than the naming of new subspecies or than disputes over the validity of scientific names, and should put an end to complaints over small personal and temporary inconveniences which regulations of the greatest importance may incidentally occasion.

WILLARD G. VAN NAME

NEW YORK STATE MUSEUM

FUNDAMENTAL EQUATIONS OF MECHANICS

TO THE EDITOR OF SCIENCE: We are greatly interested in the contribution to the teaching of elementary dynamics made by Professor Kent in his letter to SCIENCE appearing in the issue of March 19, in which he presents as the fundamental equation of mechanics $V = FTg/W$, where F , T and W are, respectively, force in pounds, time in seconds and quantity of matter in pounds, g a numerical factor of proportionality and V velocity in feet per second. This equation has the great advantage of avoiding the extremely awkward necessity involved in apparently simpler formulations of the experimental laws under consideration, of defining force in terms of mass, as so many of the more conservative physicists insist on doing, or of defining mass in terms of force, a thing which many of these conservative physicists seem to consider as the only alter-

native and which all engineering writers appear to disclaim with equal vehemence.

There can be no doubt of the difficulty of measuring quantity of matter, that is comparing the quantities of matter in two bodies, one of which is taken to be a standard, except by resorting to forces acting upon them. On the other hand, there can be no doubt of the inadvisability of attempting to preserve an international prototype force instead of a prototype quantity of matter, owing to the probability that secular changes in the elastic properties of material bodies would be vastly greater than changes in their quantity of matter. To be sure it would be possible to define the international prototype force in terms of the gravitational relation of a given body to the earth, but this would be open to the same objection as the one that was raised in regard to measuring the quantity of matter in a body by resorting to forces. We therefore think that Professor Kent has done well to retain force and quantity of matter as equally fundamental.

What seems to us as unfortunate is the necessity of defining velocity in terms of distance and time. Why not regard all dynamical quantities that are sufficiently distinct to be given different names as equally fundamental? Why stop with distance, time, quantity of matter and force? We see no reason for imposing on ourselves such a limitation.

On this principle the equation $F = ma$, to which Professor Kent objects because it is not true unless we make m an arbitrary symbol for W/g , is open also to our objection that a has been defined in terms of other magnitudes, whereas nature has furnished us with a definite acceleration, that of a body under the influence only of its gravitational relation to the earth at sea-level and latitude 45° as modified by its tendency to rise due to the rotational motion, which may well be taken as unit acceleration.

It appears to us that Professor Kent's contention is essentially this: that since the *concept* of force is independent of quantity of matter, distance and time, it is irrational to force people to take their *measure* of force from a dynamical equation involving these three sorts of magnitudes. We should take

our measure of force from some phenomenon more closely related to the concept. What we are conscious of when we lift a pound weight is not the amount of matter in it, but the force upon it.

If this sound reasoning is to be applied to all the concepts of mechanics it will be necessary to modify most of the equations slightly by introducing a proportionality factor. This has already been suggested by Professor Hoskins in a footnote to his review of Maurer's "Technical Mechanics,"¹ but he failed to make the most of his opportunity. We present here a tentative scheme only and the calculated values of a few of the constants. Our choice of fundamental units of velocity and acceleration are, we freely admit, open to the criticism of being ill-considered and off-hand. Still they will do perfectly well to illustrate the method, and certainly they are much better than the units in common use which only tend to cloud the physical entity and reality of the magnitude in question by reference to others more or less closely related. Who that has considered with any care his sensations of a passing express train does not realize that his impressions on the subject "how fast" are much more direct and elemental than any question of "how far" or "for how long"?

We begin then with the units of force, distance, time, quantity of matter and acceleration as defined above and which for our present purpose may be regarded as sufficiently unrelated to be called independent, fundamental units. What definite velocity does nature present to us that we may take as unity? After considering the peripheral and the orbital velocity of the earth and the maximum attainable velocity due to terrestrial gravitation (that of a body falling from the hypothetical "infinite distance"), it seemed well to abandon such gravitational velocities as being dangerously near to our definition of unit force (a totally unrelated concept) and adopt the velocity of light, which is one of the most definite and unalterable things in nature. This unit we call the "speedal," not from any wish to be bizarre, but merely because some name is

necessary to show where the idea leads us. 10⁻⁸ speedals we will call a micro-speedal. We see no real objection to calling it pounds, since we already employ this useful word to designate unit quantity of matter and unit force, but perhaps the present name will serve our purpose better.

Let W = quantity of matter in pounds,

S = distance in feet,

T = time in seconds,

F = force in pounds.

(Whether these are the same pounds as mentioned above or other pounds seems to be of no importance.)

V = velocity in micro-speedals,

A = acceleration in "gravitals,"

and $\alpha, \beta, \gamma, \delta$, etc., be numerical constants of proportionality. We may write the following equations:

$$V = \alpha S/T, \quad (1)$$

$$A = \beta V/T = \alpha \beta S/2T^2 = \gamma S/T^2, \quad (2)$$

where it is understood that V in equation (2) is a *change* in velocity and therefore twice the *average* velocity defined by (1). (Initial velocity being zero.)

$$F = \delta W A = \beta \delta W V/T = \gamma \delta W S/T^2. \quad (3)$$

From these three fundamental equations we may derive equations such as

$$FT = \gamma \delta W S/T = (\gamma \delta / \alpha) W V = \epsilon W V \quad (4)$$

and

$$FS = \gamma \delta W S^2/T^2 = \gamma \delta W V^2 = \zeta W V^2. \quad (5)$$

And from these, as soon as we have established units for momentum M , energy E , impulse I and work Z , and determined the constants in equations like $I = \eta FT$ and $M = \theta W V$, we could derive the equations of momentum and of energy.

The values of the constants may be easily computed. Since one micro-speedal is 1,182.9 feet per second, $\alpha = 1,182.9$. The equation for an acceleration of one foot per second per second is

$$\frac{1}{32.1740} A = \frac{1}{1182.9} \frac{V}{T},$$

which gives us at once

$$\beta = \frac{32.1740}{1182.9} = .027200.$$

¹ SCIENCE, December 4, 1914.

Also $\gamma = \alpha\beta/2 = 16.0870$. The coefficient δ is unity, which is a little unfortunate since it might lead to the erroneous impression that we were defining unit force as that force which gives unit acceleration to unit mass. Our choice of unit acceleration has probably been injudicious.

Enough has been given to illustrate the principle which we feel sure ought to commend itself to every one who once grasps the fundamental independence of all dynamical concepts and the strictly proportional nature of the dynamical equations, all of which are merely the algebraic formulation of experimental evidence. In extenuation of our introduction of a new set of numerical constants to be memorized we can only point out that there were many " $\frac{1}{2}$'s" " $\frac{1}{4}$'s," etc., there already and that we entirely do away with the troublesome and useless subject of dimensions.

The new system is not fully developed as yet, however, and until it is we have found ourselves compelled to make the best of the old one. We dodge the ambiguity in the "ambiguous words 'weight' and 'mass'" by the artifice of defining them. We adopt and we teach the convention that "mass" shall be an exact equivalent for "quantity of matter," and that "weight" means the gravitational force upon a mass. We teach that the *measure* of a force (wherever the *concept* of force may originate) may conveniently be defined by the equation $F = ma$. We teach that it is a remarkable law of nature, determined only by experiment, and not to be suspected *a priori*, that the "body factor" in this equation is strictly proportional to the weight for all bodies in the same uniform gravitational field. We point out that pounds-mass and pounds-weight (i. e., pounds-force) are totally different things, and that there are 32.2 of the units of force defined by the equation $F = ma$ in a pound-weight and that therefore all forces deduced in dynamical equations must be divided by 32.2 if we wish to express them in terms of pounds-weight, much as one would reduce centimeters to feet. Conversely, all forces given in pounds-weight must be multiplied by 32.2 before they can be used in dynamical equations. We teach that the fun-

damental idea of the gravitational constant g is force per unit mass and that it is also of the nature of an acceleration in virtue of the relation $F/m = a$. We hold that dynamics *may* be developed without the introduction of arbitrary constants by the assumption of three fundamental units and defining all the others in terms of these three. We object to Professor Kent's description of a system with four fundamental units as a "foot-pound-second" system instead of a "foot-pound-second-pound" system, and to his ridicule of the "gee-pound" or "slug" in the same letter in which he says, "It has been found convenient to use the letter m instead of W/g ." What is the unit of m if not the "slug"? We frankly talk about a unit of force called a poundal as a matter of convenience, and we measure it by a defining equation much as we measure a unit of velocity or of work. We consider this term preferable to the "pound-foot-per-second-square," and venture to hope that there may some day be introduced shorter names for the "foot-per-second-per-second" of acceleration and the "pound-foot-square" of moment of inertia.

T. L. PORTER,
R. C. GOWDY

THE UNIVERSITY OF CINCINNATI

ANOTHER STATE PARK NEEDED

TO THE EDITOR OF SCIENCE: Two or three notes of interest have appeared in SCIENCE regarding the new state reservation at Jamesville, Onondaga County, New York, which includes the glacial lake, sometimes known as West Green Lake. This little lake is of especial interest owing to its history as the site of the plunge basin of a great glacial waterfall, and also because in its environs is found the hart's tongue fern (*Phyllitis Scolopendrium*) which probably ranks as the most interesting and rarest fern in the United States.

Now it is proposed to acquire another lake of identical geological history, East Green Lake (also known as Blue Pond, and *Scolopendrium* Pond), which lies about a mile east of the west lake above mentioned. The pro-

posal was first made in the correspondence columns of a Syracuse paper, the *Post-Standard*, and has since been taken up by local people until there is considerable possibility of its ultimate success. A committee of representative business men has been appointed to further the project.

The matter is here brought to the attention of readers of *SCIENCE* in order to ask that any who can help may be moved to use their influence with state officials or any others who might render help. East Green Lake and the surrounding region represent a larger and wilder tract of land. The lake itself is of equal geological interest and from the standpoint of the hart's tongue fern, is of greater interest than the west lake region because the best specimens in the country grow near the east lake. The west lake preserve includes only seventy acres, as this was all that was of special value as park. In the east lake region it is proposed to acquire two square miles to include not only the lake plunge-basin itself but also a marl-bottomed lake nearby and additional acres of beautiful woodland.

The preservation of the best stations for the hart's tongue fern, probably the rarest and most interesting fern in North America, is sufficient reason for urging the acquirement of this proposed new park. Besides this species there are other ferns to the number of about forty, making it probably the best fern preserve in the country. The need of prompt action is indicated by the fact that a lime development company now holds an option on the tract desired.

R. C. BENEDICT

SCIENTIFIC BOOKS

Theory of Measurements. By JAMES S. STEVENS, Professor of Physics in the University of Maine. New York, D. Van Nostrand Company. 1915. Pp. vii + 81. Price \$1.25 net.

This little book is intended to fill the gap between the fragmentary treatment of the errors and adjustment of measurements, found in most laboratory manuals, and the detailed discussions given in formal treatises on the

theory and precision of measurements. In eight short chapters, the author deals with the following topics: Measurements and Errors; Probability, including a discussion of the probability curve and integral; Adjustment of Observations; Precision of Measurements; Propagation of Errors, applied to direct and inverse problems; Plotting; Negligibility, including rules for the use of significant figures; Empirical Formule and Constants.

The methods and notation adopted are similar to those employed in Merriman's "Method of Least Squares" and Holman's "Precision of Measurements." The treatment is necessarily abridged to comply with the limits set by the scope of the book but the usual formulae and methods are developed in sufficient fullness for their practical application by the intelligent student. Possibly owing to his desire to save space, the author gives very little discussion or explanation of the fundamental principles and assumptions underlying his mathematical derivations. Consequently the true significance of his results is not always apparent and the conditions essential for their correct application are apt to be overlooked. For example, the deductions from the law of accidental errors do not apply to a series of observations affected by systematic errors but the author has nowhere pointed out the necessity of considering such errors in connection with the discussion of precision.

Definitions and problems are frequently so briefly and inadequately stated that the unaided student is apt to misinterpret their meaning. The following quotation is a fair example: "Measurements are usually classified as follows: 1. *Direct*—when, for example, a distance is measured with a tape line. 2. *Indirect*—when the density of a cylinder is determined by measurements of its length, diameter and mass. 3. *Conditioned*—when the third angle of a triangle is restricted by the values of the other two angles. Measurements not so conditioned are called *independent*."

However, with the aid of a competent teacher, the student should be able to make profitable use of the book in connection with

his work in the physical laboratory and acquire some facility in determining the accuracy and significance of his measurements.

A. DE FOREST PALMER

Electric Arcs. By CLEMENT D. CHILD, Ph.D., professor of physics, Colgate University. New York, D. Van Nostrand Company. 1913. Pp. 194.

A text of this kind must interest at least two classes of readers; those who wish to know more of the physics of the electric arc and those who are intensively engaged in arc lamp development. The author has digested the results of those investigations made since the publication of Mrs. Ayrton's "The Electric Arc," which contains a similar digest of the investigations made previous to 1898.

In the first six chapters the author discusses the relations between terminal voltage, current, resistance and E.M.F. of pure carbon, impregnated carbon, pure metal and metallic oxide arcs operated with direct and alternating current in air and in various gases at different pressures. This discussion also includes the performance of the mercury arc rectifier and the mercury arc lamp under various conditions.

The seventh chapter, headed "Photometry of the Electric Arc," contains information regarding the light-producing properties of various electric arcs and scarcely touches upon the measurement of light suggested by the caption. The following chapter contains a brief review of the use of the electric arc in wireless telephony. All hypothesis regarding the electric arc is reserved for the last chapter, where the author offers an explanation of certain arc phenomena in the ionic theory.

The book would take on added interest from the scientific viewpoint if it contained references to the action of electric arcs between metal terminals in liquids such as alcohol, mineral oil, carbon-tetrachloride, etc., or high tension arcs in air. Although the book title suggests a more general discussion the author pays more attention to the "light-producing electric arc."

The text includes an extensive bibliography

to which detailed references are made at the appropriate place. The continuity of the discussion is increased by the results of the author's own investigations whenever the reports of others failed to reveal the required data. Thoroughness and presentation of many viewpoints characterize the text throughout. To the student interested in electric arc phenomena a careful reading of Mrs. Ayrton's text followed by that of Dr. Child should prove an invaluable foundation upon which to base further investigations.

SCIENTIFIC JOURNALS AND ARTICLES

THE April number (Vol. 16, No. 2) of the *Transactions of the American Mathematical Society* contains the following papers:

L. E. Dickson: "Quartic curves modulo 2."

W. A. Hurwitz: "Mixed linear integral equations of the first order."

W. B. Fite: "Prime power groups in which every commutator of prime order is invariant."

W. A. Manning: "On the order of primitive groups, II."

J. W. Alexander, II: "A proof of the invariance of certain constants of analysis situs."

A. B. Coble: "Point sets and allied Cremona groups (part I)."

C. T. Sullivan: "Scroll directrix curves."

THE April number (Vol. 21, No. 7) of the *Bulletin of the American Mathematical Society* contains: "The rôle of the point-set theory in geometry and dynamics," by E. B. Van Vleck; "An enumeration of integral algebraic polynomials," by A. B. Frizell; "Mr. Paswell's appeal to producing mathematicians," by C. N. Haskins; Review of Volterra's *Leçons sur les Fonctions des Lignes*, by G. A. Bliss; "Shorter Notices": Lehmer's List of Prime Numbers from 1 to 10,006,721, by L. E. Dickson; Whitford's *The Pell Equation*, by T. M. Putnam; Liebmann and Engel's *Die Berührungstransformationen: Geschichte und Invariantentheorie*, by T. H. Gronwall; Pasch's *Veränderliche*

und Funktion and Voss's Ueber das Wesen der Mathematik, by R. D. Carmichael; M'Lauchlan's Practical Mathematics, by T. E. Mason; Klein's Elementarmathematik vom höheren Standpunkte aus, Teil II., Netto's Elementare Algebra, Gans's Einführung in die Vektoranalysis mit Anwendungen auf die mathematische Physik, and Rothe's Darstellende Geometrie des Geländes, by T. H. Gronwall; Borel's Le Hasard, Ingersoll and Zobel's Introduction to the Mathematical Theory of Heat Conduction, and Duhem's Le Système du Monde, Tome I., by R. D. Carmichael; Lecornu's Cours de Mécanique, Tome I. and Guichard's Problèmes de Mécanique et Cours de Cinématique, by W. R. Longley; "Notes," and "New Publications."

THE May number of the *Bulletin* contains: Report of the February meeting of the society, by F. N. Cole; "The Legendre condition for a minimum of a double integral with an isoperimetric condition," by C. A. Fischer; "Note on the derivative and the variation of a function depending on all the values of another function," by G. C. Evans; Review of Sommerville's Elements of Non-Euclidean Geometry, by J. L. Coolidge; Review of Minkowski's Collected Works, by E. B. Wilson; "Shorter Notices": Bioche's Histoire des Mathématiques, by D. E. Smith; Richardson's Solid Geometry, by R. B. Robbins; Hall's Geometrical Vector Algebra, by F. L. Hitchcock; Prescott's Mechanics of Particles and Rigid Bodies, by W. R. Longley; Annuaire pour l'An 1915, publié par le Bureau des Longitudes, by E. W. Brown; "Notes"; and "New Publications."

THE June number of the *Bulletin* contains: Report of the April meeting of the society at Chicago, by H. E. Slaught; "A geometric derivation of a general formula for the southerly deviation of freely falling bodies," by W. H. Roever; "Note on solvable quintics," by F. N. Cole; Review of the Madison Colloquium Lectures on Mathematics, Part I., by O. E. Glenn; "Some books on calculus" (Granville, Snyder and Hutchinson, Davis, Vivanti), by E. B. Wilson; "Notes," and "New Publications."

SCIENTIFIC RESULTS OF THE TERRA NOVA EXPEDITION

THE British Museum has undertaken the publication of the Natural History results of the British Antarctic Expedition of 1910, better known as the Terra Nova Expedition. These results will be issued in parts as fast as they are prepared. The first part to be printed is a description of the fossil plants by Professor A. C. Seward of Cambridge.¹

An especial interest attaches to the small collection of geological specimens that were retrieved after the tragic death of Captain Scott and his heroic associates, and the present publication bears ample testimony to the fact that their efforts have not only furnished the world with a lasting monument to British pluck and manhood but have also yielded facts of the greatest scientific interest.

Although determinable fossil plants are few in number traces were seen, as well as numerous carbonaceous laminæ and small seams of coal, at a number of widely separated localities, particularly in what is called the Beacon sandstone, which at latitude 85° S. is 1,500 feet thick. This comprises an upper 500 feet of sandstone resting on 300 feet of interbedded sandstone and shale with several seams of coal, underlain by 700 feet of similar sandstone conglomeratic at the base. The character of the grains in the sandstone suggests wind action, and sun cracks and ripple marks have also been observed. This extensive formation has been traced from Mt. Nansen as far south as latitude 85°, a distance of over 700 miles.

The most significant plants are those representing the genus *Glossopteris* found at Mount Buckley or Buckley Island which is situated just west of the Beardmore Glacier in latitude 85°. These are partly referred to the widespread *Glossopteris indica* Schimper and in part described as a new variety of that species. There are also represented objects identified as those of *Vertebraria* and representing the axial organs of *Glossopteris*, and others doubt-

¹ Seward, A. C., "Antarctic Fossil Plants," British Museum (Natural History) British Antarctic (Terra Nova) Expedition, 1910. Natural History Report. Geology, Vol. 1, No. 1, pp. 1-49, tf. 1-6, maps A-C, pls. 1-8, 1914.

fully correlated with the scale leaves of the latter genus. From the Priestley Glacier rather indifferently preserved wood is described under the name *Antarcticozylon Priestleyi* and considered as a new type probably Araucarian in its relationship. Winged pollen grains are described as *Pityosporites antarcticus*. These are suggestive of the Abietinea, but may be those of the Podocarpaceae. The remainder of the collection has little interest beyond its indication of the presence of arboreal forms in high southern latitudes.

The exact age of these plant-containing beds can not be definitely determined from the present collections, although there is no reason to doubt the legitimacy of the author's conclusion that the Beacon sandstone is probably Permo-Carboniferous in age with the further possibility that its upper part may be early Mesozoic.

The demonstration of the former presence of *Glossopteris* in Antarctica is of the greatest importance. It may be recalled that during the late Devonian or early Carboniferous a flora that may be called a cosmopolitan flora, characterized by such genera as *Bothrodendron*, *Archaeocalamites*, *Archæopteris*, etc., has been found in Ellesmere Land, Spitzbergen, Greenland, Europe, North and South America, South Africa and Australia. Late in the Upper Carboniferous the floras of the world may be segregated into a northern province, of the cosmopolitan type and a southern province characterized by the *Glossopteris* flora as Neumayer termed it or the *Gangamopteris* flora as christened by David White. This latter flora, associated with glacial climatic conditions, has now been recognized from Australia, Tasmania, India, Madagascar, South Africa and South America. Its presence in Antarctica supplies an important link in the chain connecting the now isolated land masses of the southern hemisphere and also suggests the possibility of this flora having originated on the broad bosom of the Antarctic continent.

An elaboration of this theme would be out of place in the present notice. It has been somewhat fully discussed by Professor Seward in the present connection and it was also fully

discussed by David White² in 1907 in connection with his study of the flora of the coal measures of Brazil. Arber's general account³ of the *Glossopteris* flora, which was reviewed by me⁴ in these columns brought the subject down to about 1904. All of these works contain full bibliographic references to which the reader who desires to pursue the subject further is referred.

When the late Professor Heer published his first account of the Arctic fossil floras the greatest scientific interest was aroused. We have now come to see pretty clearly that existing climates may be regarded as the exception rather than the rule when geologic time is considered as a whole. This coupled with the already described accounts of Jurassic, Cretaceous and Tertiary plants from the Antarctic continent opposite from Victoria Land⁵ tends to make the discoveries announced in Professor Seward's paper seem normal and just what we should have expected. This is, however, somewhat offset by the tragedy of the Scott expedition, and it should further be remembered that demonstration has now replaced speculation and we now have a groundwork of solid facts of great importance that promise much for the future.

interesting correlations between structural characters and climate. Particularly significant in the consideration of certain problems of geology and climatology is the climatic distribution of two types of leaves and leaflets. Those with entire margins predominate in tropical, arctic and alpine regions, moors, steppes, deserts, saline situations, and other physiologically dry environments. (In this connection it should be noted that the leaves of tropical rainforests and other tropical plant communities that live in moist environments, although often of relatively large size, are semi-xerophilous in structure.) Leaves and leaflets with non-entire margins, on the other hand, are comparatively infrequent in such situations, and are very numerous in moist temperate regions having cold winters and warm summers.

In the following table are given for a number of extensive regions in the frigid, temperate and tropical zones the percentage of entire-leaved woody plants in the Dicotyledonous flora.¹

	Per Cent. Entire
<i>Frigid</i>	
Ellesmereland	100
New Zealand Alps	77
North East Siberia	65
<i>Cold Temperate</i>	
North East Germany	24
Central Russia	28
East Central North America	28
North Russia	30
England	32
Kamtschatska	33
Rocky Mountains	36
South East Siberia	37
West Siberia	44
France	44
<i>Warm Temperature</i>	
South Russia	39
East Central China	48
South East United States	49
Italy	50

¹ In the computation of the percentages given in this table woody Dicotyledons alone were used since herbaceous forms are of very infrequent occurrence in the fossil floras of the Cretaceous and early Tertiary.

Los Angeles Region	54
Spain	56

Sub-tropical and Tropical

Hongkong	71
South West Asia	72
Bombay	72
Upper Nile Region	74
Southern Africa	74
Nicaragua	76
West Indies	76
Egypt	77
South East Central Africa	78
Brazil	79
Ceylon	80
Manila	81
West Central Africa	81
Queensland	82
New South Wales	82
West Australia	83
Florida	83
South West Central Africa	83
Mauritius-Seychelles	85
Malay States	86

In the temperate regions given above there are more or less extensive areas of physiologically dry environments which are reflected in the floras by plants with relatively small entire leaves. In the tropical regions, on the other hand, there are cool uplands and shady comparatively temperate habitats which possess many plants with non-entire leaves and leaflets. The effect of these cool uplands upon the character of the foliage is well illustrated by comparing the percentage of entire-leaved Dicotyledons in the mountainous Simla region (58 per cent.) with that of the adjacent Upper Gangetic Plain (71 per cent.), and also by contrasting lowland (76 per cent.) and upland (56 per cent.) Hawaii.

In view of these facts it seems desirable to give an analysis of two floras that are more nearly homogeneous phytogeographically. The first flora, cold-temperate mesophytic, was constructed by eliminating from the flora of east central North America (east of the 95th meridian and between the 40th and 50th parallels of latitude) all plants growing on physiologically dry environments. The second flora, tropical, was formed from the woody plants of the moist lowlands of the Amazon valley.

<i>Mesophytic-cold-temperature</i>		
	Entire, Per Cent.	Non-entire, Per Cent.
Trees	10	90
Shrubs	14	86
Woody	13	87

<i>Moist-lowland-tropical</i>		
	Entire, Per Cent.	Non-entire, Per Cent.
Trees	90	10
Shrubs	87	13
Woody	88	12

From this table it is clear that leaves with non-entire margins are of very infrequent occurrence in lowland tropical floras, and those with entire margins in mesophytic cold-temperate ones. In fact the correlation between leaf structure and climate is so intimate in widely separated regions of the earth and in the distribution of many families, genera and even species that the modifying influences of environment are clearly demonstrated. For more detailed evidence, in regard to correlations between foliar structures and climate and the probable function of the non-entire leaf margin, the reader is referred to the following papers.²

It has been stated above that in moist tropical regions the leaves are of comparatively large size (megaphyllous). Any large heterogeneous tropical region will contain in consequence, among its entire-leaved plants, varying proportions of megaphyllous and microphyllous types. Similarly, in sub-tropical and warm-temperate zones the entire leaves will consist of varying proportions of these two types, depending upon the distribution of rainfall and other factors. In cold-temperate regions, however, the entire-leaves will be composed almost entirely of comparatively small-leaved types.

The percentages of entire-leaved woody

² Sinnott, E. W., and Bailey, I. W., "Foliar Evidence as to the Ancestry and Early Climatic Environment of the Angiosperms," *Am. Jour. Bot.*, Vol. II, No. 1, January, 1915; Bailey, I. W., and Sinnott, E. W., "The Climatic Distribution and Physiological Significance of Certain Types of Angiosperm Leaf-margin." *Ined.*

Dicotyledonous plants in a few Cretaceous and Tertiary floras are recorded in the next table.

<i>Tertiary</i>		Entire, Per Cent.
Eocene-Green River-Leaq		29
Eocene-Arctic-Heer		29
Eocene-Spitzbergen-Heer		46
Eocene-Bad Lands-Leaq		29

<i>Cretaceous</i>		Entire, Per Cent.
Montana-Knowlton		62
Patoot-Arctic-Heer		51
Atane-Arctic-Heer		81
Amboy-Newberry		67
Dakota-Leaq		54
Raritan-Berry		71

A comparison of the Tertiary percentages with those of modern floras indicates very clearly the general temperate character of the climates which prevailed in the regions where these fossil floras existed. Similarly, the percentages of non-entire leaves in the Patoot, Dakota and Amboy Cretaceous formations denote climatic conditions intermediate between those of tropical and temperate regions. The high percentages of entire-leaved forms (megaphyllous) in the Atane beds points to the tropical character of the climate which existed in certain arctic regions during parts of the Cretaceous.

Of course caution is needed in comparing any specific percentage in this table with that of a corresponding one in the table of living floras. This is due to the fact that one can not always be certain that any known fossil flora is a fair sample of the total ancient vegetation of which it once formed a part. Furthermore, the percentages of entire leaves in fossil and living floras must be homologous, that is, composed of similar portions of megaphyllous and microphyllous types.

In conclusion it should be noted that this method of studying fossil floras rests upon a physiological and ecological basis rather than upon the usual phylogenetic one. It promises to afford a simple and rapid means of gauging the general climatic conditions of the Creta-

ceous and Tertiary, and checking the accuracy of conclusions derived from other lines of evidence.

THE BROWN GRAPE APHID

THIS aphid is commonly known as *Macrosiphum viticola* Thomas. Unable to find any record of its complete life cycle the writers have made some observations on the form at Vienna, Va. These seem worthy of note at the present time, in view of the economic importance of the species.

The eggs are polished black and are laid during November or late October. They are placed in the axils of the leaves of *Viburnum prunifolium* Linn. In the spring they hatch before the leaves open and the young feed on the bursting flower buds. The stem mother appears unlike a *Macrosiphum*, having short cornicles. Late in April, or in early May, the second generation matures and this nearly all becomes alate.

Such alate forms are unable to subsist on the *Viburnum*, but migrate to the grape and produce the third generation on that plant. Here the species lives throughout the summer, producing apterous and alate forms. We have also some intermediates similar to those recently described by us in *Aphis pomi* DeGeer. These intermediates were taken in May and June.

The fall migrants are unlike the spring migrants in sensory characters, the sensoria on the antennae averaging about as follows: Segment III., 30; IV., 25; V., 15. These fall migrants may be found depositing their young upon the *Viburnum* leaves during the middle of October.

The ovipara is apterous and, after being fertilized by the alate male, deserts the leaves and migrates to the twigs in order to deposit her winter eggs.

VIENNA, VA.

THE RELATION OF MITOCHONDRIA TO GRANULES OF THE VITAL AZO DYES¹

THE more ardent hopes which relate to the subject of vital staining are perhaps connected with the successful staining of living, preformed components of the cell. Instances of such a phenomenon are often enough alleged without sufficient substantiation. Goldmann,² whose papers did so much to attract general interest to this subject, believed that the dyes, isamine blue and trypan blue, must be looked upon as combining with some preformed, but hitherto unidentified, elements of the living cell, and this is substantially the attitude of Kiyono,³ who has added the latest considerable contribution to this subject. Tschaschin⁴ of Maximow's laboratory has given this hypothesis its most concrete formulation by claiming that we are dealing with an elective, truly vital staining of the mitochondria of connective tissue cells. On the other hand, Evans and Schulemann⁵ came to the conclusion that the process of staining with these dyes is more intelligible as an ultra-microscopic phagocytosis, and interpreted the dye granules as storage phenomena, in no way related to the living elements of the cell. In view of this discrepancy in the points of view of different workers, a cytological study of some of the cells which react to azo dyes has been suggested by Dr. Evans and carried out under his direction.

The study has been limited to cells of subcutaneous tissue in adult mice. As has been

¹ From the anatomical laboratory of the Johns Hopkins Medical School, Baltimore.

³ Kiyono, "Die vitale Karminspeicherung.," Fischer, 1914.

⁴ Tschaschin, S., *Folia Haematologica*, Bd. XIV., S. 295, 1912; Bd. XVI., S. 247, 1913, Bd. XVII., S. 317, 1913.

⁵ Evans and Schulemann, *Jahresb. d. Sch. Ges. f. Nat. Kwl.*, 1913; *SCIENCE*, Vol. XXXIV., p. 443, 1914; *Deut. med. Wochenschr.*, No. XIII., 1914.

described by Tschaschin, Evans and Schulemann, and others, the two common types of connective tissue cells are readily distinguished by their reaction to the vital stain, the plasmatocytes storing large masses, the fibroblasts much more minute granules of the dye. It can not be denied that the delicate punctate and rod-like deposits of isamine blue, as seen in fibroblasts, often make an astonishingly close approach to mitochondria in appearance. But are they mitochondria? This question could only be answered by applying to the cells in question the criteria for the recognition of mitochondria, which are well known to cytological technique. We have confined ourselves to three methods, which have been pursued until they yielded constant and reliable results. These are the iron hematoxylin method, the aniline acid-fuchsin methyl-green method (Bensley), and supra-vital staining with janus green (Michaelis, Laguesse, Bensley, Cowdry).

On studying in this way the fibroblasts of the mouse, mitochondria can easily be demonstrated. They disagree in several respects with the alleged isamine blue mitochondria. The true mitochondria are always scantier in number than the deposits of isamine blue which occur in fibroblasts of chronically stained animals, and they are more definitely threadlike than the isamine blue structures. Further, it is quite possible to see the unstained mitochondria lying between the isamine blue granules in living cells, examined immediately after removal from the body, and finally, by staining with janus green, one can see these previously unstained structures now add themselves to the number of stained cytoplasmic elements, where their peculiarities as regards color, shape, size and arrangement are still retained. These conclusions obtain even more emphatically with trypan blue and presumably with all of the benzidine dyes.

In the vital staining with azo dyes, it is not true, consequently, as Tschaschin maintains, that we have a vital staining of the mitochondrial apparatus in some cells, in addition to the gross reception of the dye by the macrophages. Indeed, Tschaschin believes that in the macro-

phages themselves the mitochondria are stained vitally, but that here they are exclusively granular, spherical forms, and suffer all stages of transformation into the large "secretory" granules. The methods detailed for the study of fibroblasts yield essentially similar results when applied to the macrophages. These, in contradistinction to the claim of Tschaschin, have true mitochondria, some of them filiform, among the azo dye granules.

This discussion has wider implications, for Tschaschin's ideas have been accepted by Kiyono even though he recognizes some anomalous aspects of such a conclusion. Kiyono seems willing to believe that the macrophages may react to these dyes in a phagocytic or physical way but that this can not be the explanation for all the granules produced by these dyes, since the reception and storage of foreign substances by some of the other cells which are vitally stained is a phenomenon unknown by other methods. This argument seems beside the point. We can only state that in no case known to us have the granules produced by vital azo dyes been found to be identical with the mitochondria of the vitally stained cells.

KATHERINE J. SCOTT

THE AMERICAN PHILOSOPHICAL SOCIETY

THE annual general meeting of the American Philosophical Society was held in the rooms of the society in Philadelphia on April 22, 23 and 24. The meeting was opened on Thursday afternoon by President W. W. Keen, who, with Vice-presidents A. A. Michelson, W. B. Scott and Professor C. L. Doolittle, presided over the various sessions.

On Friday evening a reception was held in the hall of the Historical Society of Philadelphia, at which William Morris Davis, Sc.D., Ph.D., professor emeritus of geology, Harvard University, gave an illustrated lecture "On New Evidence for Darwin's Theory of Coral Reefs." The lecture described the chief results of a Shaler Memorial Voyage across the Pacific in 1914, with studies of the Fiji group, New Caledonia, the Loyalty Islands, the New Hebrides, the Great Barrier Reef of Australia and the Society Islands.

On Saturday afternoon a symposium was held on the Figure, Dimensions and Constitution of the Interior of the Earth. The subject was discussed

from the astronomical standpoint by Frank Schlesinger, Ph.D., director of Allegheny Observatory, Pittsburgh; from the geological standpoint by T. C. Chamberlin, Ph.D., LL.D., head of department of geology, University of Chicago; from the seismological standpoint by Harry Fielding Reid, Ph.D., professor of dynamical geology and geography, Johns Hopkins University, Baltimore; from the geophysical standpoint by John F. Hayford, director of college of engineering, Northwestern University, Evanston, Ill.

Fifteen new members were elected, the names of whom have been given in *SCIENCE*, Vol. XLI., page 640. The usual practice of electing foreign members was omitted this year.

The portrait of Dr. Edgar F. Smith, provost of the university and former president of the society, was presented by a donor whose name was withheld. The address of presentation was made by Vice-provost J. H. Penniman.

The meeting closed with a dinner at the Bellevue-Stratford, attended by about one hundred members and guests. The toasts were responded to as follows:

"The Memory of Franklin," by Hon. Simeon E. Baldwin.

"Our Universities," by Professor Harry Fielding Reid.

"Our Sister Societies," by Professor Ernest W. Brown.

"The American Philosophical Society," by Professor Marion D. Learned.

The following papers were presented during the various sessions of the society:

Devices for Facilitating the Analysis of Observations—More Particularly those of the Tides:
ERNEST W. BROWN.

On Linear Integral Equations in General Analysis:
ELIAKIM H. MOORE.

The paper opens with a brief account of the author's general theory of linear integral equations, a theory embracing by specialization the regular cases of various classical instances, and in closing it indicates a new general theory intended to embrace the most important irregular cases of the classical instances.

A Direct Solution of Fredholm's Equation with Analytic Kernel: PRESTON A. LAMBERT.

The Existence of a Sub-electron? ROBERT A. MILLIKAN.

The Work in Atmospheric Electricity aboard the "Carnegie": L. A. BAUER AND W. F. G. SWANN.

Local Disturbances in a Magnetic Field: FRANCIS E. NIPHER.

Explorations over the Surface of Telephonic Diaphragms Vibrating under Simple Impressed Sounds: A. E. KENNELLY AND H. O. TAYLOR.

The Hall and Corbino Effects: EDWIN PLIMPTON ADAMS.

The Hall effect is the production of a transverse difference of potential in a conducting sheet when an electric current flows through it and it is placed in a magnetic field perpendicular to its plane. The Corbino effect is the production of a circular current in a conducting disk when a radial current flows through it and it is placed in a magnetic field perpendicular to its plane. This paper describes experiments that have been made to study the latter effect and to show its essential relation to the Hall effect. The symmetry of the experiment arranged for measuring the Corbino effect, as well as the fact that the measurement of the Hall effect requires very thin sheets, gives to the Corbino effect an important position among the galvanomagnetic effects.

Spontaneous Generation of Heat in Recently Hardened Steel: CHARLES FRANCIS BRUSH.

The writer shows that the specimens of carbon tool steel and tungsten "high speed" steel examined by him spontaneously generated a very considerable amount of heat at room temperature after being water-hardened at cherry-red or white heat; that the development of heat at steadily diminishing rate was observable more than a month, and was accompanied by shrinkage in volume of the steel. Progress of heat generation and of shrinking is shown in curves. But that shrinking is only incidental to, and is not the prime cause of the generation of heat is evidenced by the fact that the internal work represented by the heat generated is hundreds of times greater than necessary to produce the observed change in volume.

The writer further shows that in the process of hardening, the steels increased at least a half per cent. in volume, evidenced by specific gravity tests of half-inch bars and linear measurements of long thin rods; that when afterward tempered to light-blue color much shrinkage took place at once, followed by more shrinkage when tempered to light-blue color, and another large shrinkage when annealed.

The writer regards the hardened steel as being in a condition of very great molecular strain somewhat unstable at first. Spontaneous relief of a small portion of the strain causes the generation of heat observed until stability at room temperature

is reached. Any considerable rise of temperature, as in tempering, permits further spontaneous relief of strain, or molecular rearrangement, doubtless accompanied by more generation of heat, and so on until annealing temperature is reached. It is obvious that the process of tempering or annealing steel is an exothermic one, and conversely that hardening is an endothermic process.

Diagrams of the apparatus employed are shown and described, and analyses of the steels given.

Etching and Performance of a Ten-inch Diffraction Grating: A. A. MICHELSON.

One-Dimensional Gases and the Reflection of Molecules from Solid Walls: ROBERT WILLIAMS WOOD.

Heredité in Protozoa: M. H. JACOBS.

In the higher animals, characters are not for the most part directly transmitted from one generation to the next, but develop anew in each generation from the germ-plasm. In the protozoa, on the other hand, there is a mixture of direct transmission and new development that has interesting consequences in the case of the inheritance of newly acquired characters. In this connection a race of *Paramecium* with three contractile vacuoles instead of the usual number of two is discussed, and the means described by which the unusual number is kept from disappearing. The factors concerned seem to be: (a) direct transmission of the extra vacuole, (b) a tendency to adhere to ancestral racial trails, and (c) a new tendency of the protoplasm to produce extra vacuoles.

The Constitution of the Hereditary Material: T. H. MORGAN.

The Problem of Adaptation as Illustrated by the Fur Seals of the Pribilof Islands: GEORGE H. PARKER.

The Alaskan fur-seal is a pelagic animal that breeds in summer on the Pribilof Islands, Behring Sea. About equal numbers of males and females are born. At the breeding age one male, the bull, becomes associated with a number of females, the cows, thus constituting a harem. A harem may contain as many as 120 cows and probably averages about 30. As a result of this disproportionate relationship as compared with the proportion of the sexes at birth, there are to be found at most breeding-grounds many so-called idle bulls. These are a measure of the inefficiency of organic adaptation. Contrary to the opinion held by many biologists, adaptation is not always a relation of great exactitude, but is often, to use the words of Bateson, a poor fit.

An Interpretation of Sterility in Hybrids: EDWARD M. EAST.

Heterosis and the Effects of Inbreeding: GEORGE H. SHULL.

Physiological processes are stimulated and rate of growth and total amount of growth increased through the union of gametes having unlike constitution. This physiological effect of the differences in uniting gametes is heterosis. Inbreeding lessens heterosis by gradually lessening the differences between the uniting gametes. The application of this principle to some of the problems of practical breeding was briefly discussed.

*The Significance of Sterility in *Oenothera*:* BRADLEY M. DAVIS.

Studies on the seed, ovule and pollen sterility in *Oenothera* show that there are species with a high degree of fertility and species in which fertility is low, also that hybrids may exhibit a wide range in comparative fertility. These conditions suggest the possibility that hybrids may at times continue indefinitely as impure or heterozygous species through a failure to produce homozygous zygotes or through the mortality of zygotes having homozygous constitutions. *Oenothera Lamarckiana* is a form with low seed fertility and a high degree of pollen and ovule sterility, and may be representative of an impure species, hybrid in character, which for the most part breeds true, but occasionally and repeatedly produces other types, the so-called mutants. In genetical work with *Oenotheras* a method of germinating seeds must be employed which will give trustworthy proof that a culture has produced all of the seedlings possible from a sowing of seed-like structures.

*Morphology and Development of *Agaricus rodmani*:* GEORGE F. ATKINSON.

Agaricus rodmani, which is closely related to the cultivated mushroom, *Agaricus compestris*, has a thick, double annulus, which is divided into an upper and lower limb by a broad, marginal groove nearly reaching the stem. This peculiar annulus, especially the lower limb, has suggested a resemblance to the volva of the *Amanitae*. While it arises from the surface of the pileus margin, and is composed to some extent of a portion of the blematogen, it is not strictly comparable to the volva, since the blematogen in the species of *Amanita* thus far studied is clearly separated from the pileus by a distinct cleavage layer, while in *Agaricus* it remains "concrete" with the pileus.

The pileus and stem fundaments are differentiated by the appearance of an internal, narrow zone of young, slender hyphae, rich in protoplasm, the primordium of the hymenophore and pileus margin. These hyphae are directed obliquely downward.

The rapid increase in the elements of this primordium produces a tension on the ground tissue below it, which now lags behind in growth, so that it is torn apart, forming an annular cavity in the angle between the stem and pileus.

The pileus margin and the hymenophore primordium increase in a centrifugal direction. The palisade stage of the hymenophore begins next the stem. In certain individuals it also extends partly down on the stem. The hymenophore primordium consists of a zone of parallel, slender hyphae, the ends of which are not crowded, thus presenting a more or less frazzled appearance on its lower surface. The transition to the palisade stage occurs by the increase in number of these hyphae and the broadening of their free ends.

The lamellae originate as radial, downward-growing salients of the palisade zone, beginning next the stem, in some individuals also arising on the upper part of the stem. Since the growth and increase of these parts of the hymenophore, as well as that of the pileus margin, is centrifugal, all stages of the young hymenophore are therefore found in a single individual during an intermediate stage of its development; the zone of gill salients next the stem, followed by the palisade zone, and outside of this the primordial zone.

The Large-fruited American Oaks: WILLIAM TRELEASE.

Relationships of the White Oaks of Eastern North America: M. V. COBB.

The Present Need in Systematic Botany: L. H. BAILEY.

A Convenient Form of Receiver for Fractional Distillations under Diminished Pressure: MARSTON T. BOGERT.

A simple form of apparatus was exhibited and described which permits the collecting and measuring of fractions of any size and number.

The Cymene Carboxylic Acids: J. R. TUTTLE AND MARSTON T. BOGERT.

The authors have prepared the two isomeric p-cymene carboxylic acids, p-cymene 2-carboxylic acid and p-cymene 3-carboxylic acid, from the corresponding bromo compounds, by the well-known Barbier-Grignard reaction (metallic magnesium and anhydrous ether, followed by carbon dioxide).

Small amounts of the 2-acid have been obtained heretofore by other investigators, and a few salts have been recorded; but we believe that this is the first time that the acid has been obtained in sufficient amount to be extensively studied. The authors have prepared, in addition to the free acid, various salts, esters and other derivatives.

The isomeric 3-acid appears to be entirely new. Its properties and those of certain of its derivatives are described by the authors.

These acids are members of the benzoic acid series, and this paper is therefore a contribution to our knowledge of a very important group of organic acids.

Syringic Acid and its Derivatives: E. PLAUT AND MARSTON T. BOGERT.

In the bark and leaves of the lilac (*Syringa vulgaris*), and in the bark of the privet (*Ligustrum vulgare*), there occurs a substance which has been called "syringin," "lilacin" or "ligustrin." When this substance is oxidized with potassium permanganate, it yields glucosyringic acid, and this latter is easily saponified to dextrose and syringic acid.

The authors obtained their syringic acid by the method of Bogert and Isham (treating trimethyl gallic acid with fuming sulphuric acid), and have prepared therefrom and studied a number of new derivatives; among them being bromo, nitro, amino and hydroxy syringic acids, esters, acetyl derivatives, and ortho condensation products.

The Relation of Ductless Glands to Dentition and Ossification: WILLIAM J. GIES.

Gastro-Intestinal Studies: PHILIP B. HAWK.

On the Rate of Evaporation of Ether from Oils and its Application in Oil-ether Colonial Anesthetics: CHARLES BASKERVILLE.

The rate of evaporation of oil-ether mixtures containing 25, 50 and 75 per cent. of the latter was determined at body temperature. The oils used were olive, peanut, corn, cottonseed, soya bean, cod liver and lanolin.

The speed at which the ether evaporated from the 75 per cent. mixture was found clinically to be the best for introducing and maintaining anesthesia in the human subject by insertion in the colon. The technique is indicated for operations about the head, throat, mouth and the buccal cavity.

Dr. Gwathmey, the senior collaborator has records of over a thousand cases with different operators without a single case of post-anesthesia pneumonia and with nausea reduced to the minimum.

Oral Endamebiasis: ALLEN J. SMITH.

Certain Factors Conditioning Nervous Responses: STEWART PATON.

The Rights and Obligations as to Neutralized Territory: CHARLEMAGNE TOWER.

Physiographic Features as a Factor in the European War: DOUGLAS W. JOHNSON.

The paper describes the salient features of geological structure west of the Rhine and explains the influence of this structure upon surface topography. Special attention is given to the Rhine graben and the strong contrast between the steep eastern and gentle western slope of the Vosges; the maturely dissected peneplane of western Germany and the Ardennes, trenched by the incised meandering valleys of the Rhine, Moselle and Meuse; the concentric cuestas northeast and east of Paris with their steep escarpments facing toward the Germans; and the comparatively level plains of central and northwestern Belgium. In the eastern field the East Prussian lake district, the plain of Poland, the Podolian cuesta and the Carpathian Mountains are briefly described.

It is shown that in both theaters of war landforms have exercised an important influence both upon the general plans of campaign and the detailed movements of armies. Topography limited the German invasion of France to four principal routes, which are described and illustrated by lantern views. The violation of Belgian neutrality had a very distinct topographic basis. Russia's plan of campaign has been dictated in part by topographic considerations, and the principal battles in the east have been fought with reference to natural lines of defense which are illustrated by diagrams. Suggestions are made as to the effect of landforms upon probable future movements of the armies.

Tammus and Osiris: GEORGE A. BARTON.

The Pronouns and Verbs in Sumerian: J. DYNELEY PRINCE.

Opium in the Bible: PAUL HAUPT.

In ten passages of the Old Testament Hebrew *rosh*, head, denotes a bitter and poisonous plant. It is used also of the poison of serpents. According to Pliny the venom of snakes was nothing but bile. The ancients used the same word for gall, bitterness, poison, medicine. We use "to drug" for "to narcotize," although "drug" originally means simply a dry (German *trocken*, Dutch *droog*) herb. *Rosh* is mentioned in the Bible in connection with *la'arsh*, wormwood or absinthe.

It was a plant which grew in the furrows of the fields (Hosea, x., 4). The Authorized Version renders "hemlock," but *rosh*, head, denotes poppy-head, and *me-rosh* is opium. Also the gall (k. c., bitter fluid) with wine (not vinegar) in the account of Christ's crucifixion (Matthew, xxvii., 34) and the myrrh in Mark xv., 23 denote opium. The Talmud states that a cup of wine with *lebondh* was given to criminals before their execution. *Lebondh* means "incense," as a rule, but in this case it is used for opium. In the fifth chapter of the Alexandrian festal legend for the feast of Purim, known as the Third Book of the Maccabees, we read that wine with incense was given to the elephants before they were let loose upon the Jews. This "incense" may have been a preparation of Indian hemp. *Assassin* means intoxicated with hashish (*Cannabis Indica*).

Divisions of the Pleistocene of Europe and the Periods of the Entrance of Human Races: HENRY FAIRFIELD OSBORN.

The Occurrence of Algae in Carbonaceous Deposits: CHARLES A. DAVIS.

On account of their generally small size and fragile structure, Algae have not usually been recognized as important contributors to carbonaceous rocks, and some recent students of the microscopic structure of coals have denied the probability of their existence as fossils in carbonaceous rocks. Under certain conditions of deposition and preservation, as yet unknown, Algae may constitute a large percentage of the recognizable plant remains which have accumulated to form beds of carbonaceous shales of great extent and thickness. Some micro-photographs of Algae from the oil-yielding shales of Green River are shown.

Additions to the Fauna of the Lower Pliocene Snake Creek Beds, Nebraska: W. J. SINCLAIR.

The Snake Creek beds explored by the Princeton Expedition of 1914 are found in the northwest corner of Nebraska in Sioux Co., and consist of unconsolidated gravels and sands in which water-worn bones of a large number of fossil animals of Lower Pliocene age are found. Most of these remains are fragmentary and there is almost no association of parts. We were fortunate in securing rather better material than has hitherto been collected from this formation, and have a number of new forms now described for the first time. Most of the remains are of horses, of which there were at least a dozen different species on the Lower Pliocene plains of Nebraska, most of them three-toed. There were also several different kinds

of camels, some of them quite large, at least three rhinoceroses, many carnivorous animals, some of large size, at least two mastodons, a peccary, the last of the oreodons or "ruminating hogs" as Professor Joseph Leidy called them, an antelope of entirely new type, quite different from anything hitherto reported from North America, with scimitar-shaped horns sloping backward and curving inward, circular at the base but flattening out toward the tips. There is still another antelope, *Dromomeryx*, but no trace of the pronghorn. In collections made by the American Museum from the Snake Creek beds the first of the bison appears, so the Snake Creek fauna gives us some idea of the kinds of animals on the buffalo range when the buffalo first came, and shows what great faunal changes have taken place even during the lifetime of this genus.

The Role of the Glacial Anticyclone in the Air Circulation of the Globe (illustrated by lantern slides): WILLIAM H. HOBBS.

The paper presents in outline a theory of nourishment of the great continental glaciers of the polar regions, and shows in what ways this theory, first promulgated by the author in 1910, has been confirmed and extended by the work of the numerous exploring expeditions carried out since that date. It is particularly because the expeditions across Greenland of 1912 (deQuervain) and of 1913 (Koch and Wegener), and those of Scott and Amundsen into the heart of the Antarctic continent, have for the first time penetrated the central areas of continental glaciers that the newer studies are illuminating. The penetration of higher levels of the atmosphere upon the borders of the inland ice through the aid of pilot balloons, has supplied further evidence of great value along a wholly new direction. Most recent of all, the studies of Sir Douglas Mawson within a new section of the Antarctic continental glacier has brought valuable confirmatory observations.

Note on the Sun's Temperature: HENRY NORRIS RUSSELL.

The effective temperature of the sun may be computed from Abbot's data for the radiation of each separate wave-length, using Planck's formula. The resulting temperature at the center of the disk is about 6600° when determined from the visible radiation, but 600° lower according to the radiation in the infra-red. The effective temperature at the edge of the sun is more than 1000° lower, which accords with the theory that at the

center of the disk we can see down deeper, into hotter layers.

Some Results from the Observation of Eclipsing Variables: RAYMOND S. DUGAN.

Slides showing observed light-curves of three giant eclipsing variables: RT Persei, Z Draconis and RV Ophiuchi; and diagrams of the binary systems whose revolution is supposed to give rise to the observed light variations. The importance of repeatedly observing the entire period shown in the discovery of shallow secondary minima, the oblateness of the stars, inter-radiation and periastron effects and darkening toward the limb. Evidence of the greater brilliance of the advancing side of the bright star. The variation of the periods of these three stars. Early Harvard photographs and recent photometric observations extend the observations of Z Draconis over nearly 7000 periods and of RT Persei over nearly 11,000 periods. Comparison of the visual and photographic light curves.

The Variable Stars TV, TW and TX Cassiopeiae: R. J. McDIARMID.

A brief discussion of the light curves of the variable stars TV, TW, TX Cassiopeiae and T Leonis Minoris was given, pointing out interesting features in connection with each system.

In the system TV Cass. we have two stars of nearly the same size but of different surface brightness, the ratio being 5.5 as to 1.0. In this system other points of interest are brought out, such as the reflection and ellipticity effects. The system TW Cass. represents two stars of almost equal brightness and of nearly the same size, moving in an eccentric orbit. In the third system TX Cass. the two stars are very unequal in size, with a ratio of surface brightness of 1.0 to 1.5. The stars are ellipsoidal in shape, giving rise to an ellipticity effect shown by the light curve. The system is of special interest, as there seems to be little doubt of its being similar to the sun, bright at the center, decreasing in brightness toward the limb. T Leonis Minoris is an eclipsing variable. The ratio of the surface of the two stars in the eclipsing system T. Leonis Minoris is 1 as to 25.

Radial Velocities in the Orion Nebula: EDWIN B. FROST.

The investigations of the nebula in Orion by Meers, Bourget, Fabry and Buisson, of Marseilles, published in the *Astrophysical Journal* for October, 1914, show that the photographic interferometer method can be successfully applied to the study of the radial velocities of the nebula,

both as a whole and in its separate parts. Their conclusions that there are very appreciable motions in closely adjacent portions of the nebula have been confirmed by observations made in the last few weeks with the Bruce spectrograph. Differences of over 10 km. per second in the velocity in the line of sight have been found, and the general effect of rotation of the nebula inferred by the French observers is confirmed by the spectrograph.

The Euler-Laplace Theorem on the Rounding Up of the Orbits of the Heavenly Bodies under the Secular Action of a Resisting Medium: T. J. J. See.

HORACE CLARK RICHARDS

THE AMERICAN PHYSICAL SOCIETY

A REGULAR meeting of the American Physical Society was held at the National Bureau of Standards, Washington, on Friday and Saturday, April 23 and 24, 1915.

Friday, 2 P.M.

Hon. William C. Redfield, Secretary of Commerce, opened the meeting with a cordial address of welcome in which he gave strong expression to his interest in the progress of science, and his appreciation of the vital interdependence of physics and the commercial interests of the country.

Papers were presented as follows:

"On the Distributed Capacity of Single Layer Solenoids," by J. C. Hubbard. (By title.)

"The Skin Effect in Bimetallic Wires," by John M. Miller.

"Magnetization by Rotation," by S. J. Barnett.

"Intercomparisons of the Standard Instruments at Magnetic Observatories 1905-1914," by L. A. Bauer.

"Simultaneous Readings in Electrical Measurements, with Demonstration of a New Type of Switch for Facilitating Them," by Walter P. White.

"The General Design of Critically Damped Galvanometers," by Frank Wenner. (By title.)

"Apparatus for the Simultaneous Measurement of Length, Electrical Resistance, and Magnetic Permeability as Functions of the Temperature," by Arthur W. Gray. (By title.)

"The Dielectric Constant of a Heterogeneous Dielectric," by H. L. Curtis and M. James.

"The Separately Excited Electrodynamometer

as a Sensitive Galvanometer," by Ernest Weibel.

"The Crushing of a Hollow Conductor by Lightning," by W. J. Humphreys. (By title.)

"Aneroid Barometers," by M. D. Hersey.

"A Method of Measuring Heat Conductivities," by R. W. King.

"Viscosity of Ethyl Ether near the Critical Temperature," by A. L. Clark.

"An Equation of State for Normal Substances, Tested in the Vapor Dome," by Harvey N. Davis.

"The Correction of Echoes in the Auditorium at the University of Illinois," by F. R. Watson. (By title.)

"The Transpiration of Plants in Relation to Temperature and Solar Radiation," by Lyman J. Briggs and H. L. Shantz.

"A Mercurial Barometer in which the Well Setting is Eliminated," by Lyman J. Briggs.

Saturday, 9:30 A.M.

"The Reflecting Power of Metals for the Ultra-Violet Region of the Spectrum," by Edward O. Hulburt.

"The Visibility of Radiation in the Red End of the Visible Spectrum," by Edward P. Hyde and W. E. Forsythe.

"The Effective Wave-Length of Transmission of Red Pyrometer Glasses and other Notes on Optical Pyrometry," by Edward P. Hyde, F. E. Cady and W. E. Forsythe.

"The Use of a Hollow Filament with Perforations in the Determination of the Black-body-Temperature and True-Temperature Relation for Tungsten," by A. G. Worthing.

"A Further Extension of the Spectrum in the Extreme Ultra-Violet," by Theodore Lyman.

"The Fluorescence and Absorption Spectra of Uranyl Nitrate," by E. L. Nichols and Ernest Merritt.

"A Precision Artificial Eye," by Herbert E. Ives. (By title.)

"A Flicker Photometer Attachment for a Lummer-Brodhun Photometer Head," by E. F. Kingsbury.

"Color Grading and Color Specifications by Means of the Rotary Dispersion of Quartz," by Irwin G. Priest and Chauncey G. Peters. (By title.)

"A Proposed Method for the Photometry of Lights of Different Colors," by Irwin G. Priest.

"On X-ray Wave-lengths," by William Duane and F. L. Hunt.

"The X-ray Spectrum of Tungsten at Constant Potential," by David L. Webster.

"Factors Governing the Darkening of a Photographic Plate by X-rays," by J. S. Shearer.

"The Wave-length Sensibility Curve for Isolated Crystals of Selenium between 200 μ and 450 μ ," by L. P. Sieg and F. C. Brown.

"The Variation of Equilibrium Conductivity of Selenium with the Intensity of Illumination," by F. C. Brown.

"The Effect of Variation of Temperature on the Coefficient of Recombination of Electrons in Selenium Crystals," by Kathryn J. Dietreich.

Saturday, 2 P.M.

"A Null Method with Photo-electric Cells," by F. K. Richtmyer.

"New Tests of Einstein's Photo-electric Equation," by R. A. Millikan.

"Factors Affecting the Relation between Illumination and Photo-electric Current," by Herbert E. Ives, Saul Dushman and E. Karrer.

"The Theory of Adsorption," by Irving Langmuir.

"The Law of Stokes and the Removal of Particles from Fluids," by W. W. Strong.

"Ionization Potential of an X-ray Tube," by E. C. Drew. (Introduced by Horace C. Richards.)

"Parson's Magnetron Theory of Atomic Structure," by David L. Webster.

"A Conducting Paint," by M. James.

"Mechanical Strain and Thermo-electric Power," by Walter P. White.

"Recent Results and Conclusions Regarding Specific Heats at Moderate and High Temperatures," by Walter P. White. (By title.)

"Geometrical Tripods and Stands," by Lyman J. Briggs.

"Changes in Electrical Resistance Accompanying Thermal Expansion," by Arthur W. Gray.

"The Ballistic Use of a Moving Coil Galvanometer in Measuring Discharges Obeying the Exponential Decay Law," by A. G. Worthing.

"The Mobilities of Ions in Air," by E. M. Welsh.

"The Effect of a Magnetic Field on the Initial Recombination of the Ions Produced by X-rays," by J. E. M. Jauncey. (By title.)

"An Accurate Method for the Measurement of the Conductivity of Electrolytes," by W. A. Taylor and H. L. Curtis. (By title.)

The thanks of the society were extended to the Washington members for the lunch generously provided on Saturday for all visiting physicists and to the Bureau of Standards for numerous courtesies extended.

On Friday evening a large number of the members in attendance dined together at the Cosmos Club. This pleasant feature was arranged for and carried out by Dr. L. J. Briggs of the Bureau of Plant Industry.

The attendance at all sessions was good, and there was considerable profitable discussion of papers. On account of the length of the program, a number of local members courteously yielded their time to others and presented their papers by title only.

A. D. COLE,
Secretary

THE ENTOMOLOGICAL SOCIETY OF AMERICA

THE ninth annual meeting of the Entomological Society of America was held at the University of Pennsylvania on December 31, 1914, and January 1, 1915, in affiliation with the American Association for the Advancement of Science. The meetings were all well attended, but from the shortness of the time and the amount of business to be transacted several papers had to be read by title.

The annual public address was delivered on Wednesday evening, December 30, at the Academy of Natural Sciences by Professor Stephen A. Forbes, of the University of Illinois, on the subject: "Ecological Foundations of Applied Entomology." At the same meeting Dr. Henry Skinner, of the Academy of Natural Sciences, gave "A History of the Entomological Society of America." The visiting entomologists were entertained by the local entomologists at a smoker after the addresses.

The following papers were presented:

"Food Habits of Some Colorado Aphids," by C. P. Gillette.

"The Poison Glands of *Automeris* to Fabr.," by Cornelia F. Kephart.

"Geographical Distribution of Neuropteroid Insects, together with Analysis of Our Insect Fauna," by Nathan Banks.

"The Biology of *Nymphula maculalis* Clemens," by Paul S. Welch. Read by title.

"Modification of Tiger-beetle Colors by Temperature and Moisture," by V. E. Shelford.

"Life-history, Development and Work of Unspotted Tentiform Leaf-miner of Apple," by L. Haseman. Read by title.

"Pupal Characters Used in the Classification of the Sphingids," by Edna Mosher. Presented by the secretary.

"Results of Twenty-five Years' Collecting of the Tachinidæ," by J. M. Aldrich.

"Notes on Capsid Life-histories," by Mortimer D. Leonard.

"Notes on the Life-histories of Certain Membracids," by W. D. Funkhouser.

"A Photographic Record of the Development of the Female *Lepidosaphes ulmi* Linn.," by R. A. Cooley.

"On Proper Generic Concepts," by C. H. Tyler Townsend.

"The Homology of the Genitalia of *Benacus griseus*," by Anna Grace Newell.

"The Nemocera not a Natural Group of Diptera," by Frederick Knab.

"Studies on the Morphology of the Head and Mouth-parts of Diptera," by Alvah Peterson. Read by title.

"Interpretation of the Codling-moth Data from Colorado," by C. P. Gillette.

"Modification of the Color Patterns of *Cicindela* by Temperature and Moisture," by V. E. Shelford. Read by title.

"Suggestions for Discovering Affinity and Phylogeny," by Nathan Banks.

"Insect Notes from Colorado," by C. P. Gillette.

"The Modification of the Subcostal Vein in the Wings of Insects," by Alex. D. MacGillivray. Read by title.

"The Olfactory Sense of Coleoptera," by N. E. McIndoo.

"The Ecology of Plague," by James Zetek. Read by title.

"Importance of Observations Apparently Unimportant," by F. M. Webster. Read by title.

"Life-history Studies on the Cercopidæ and Jassidæ," by Herbert Osborn.

"An Insect Enemy of the Four-lined Leaf-bug," by C. R. Crosby. Read by title.

The greater part of the morning of the first was devoted to the business meeting at which was reported the election of Rev. Charles J. S. Bethune, Professor John Henry Comstock, Professor Charles Henry Fernald and Mr. Eugene Amandus Schwarz as honorary fellows.

The following members were elected as fellows: Nathan Banks, J. Chester Bradley, W. E. Britton, C. T. Brues, H. T. Fernald, Glenn W. Herwick, J. S. Hine, O. A. Jobannese, A. L. Melander, A. P. Morse, P. J. Parrott, Edith M. Patch, A. L. Quahtance, J. A. G. Rehn, W. A. Riley, Annie

Trumbull Slosson, E. M. Walker, H. F. Wickham and E. B. Williamson.

One of the most important features of the meeting was the establishment of the Thomas Say Foundation. A serial for the publication of works dealing with American systematic entomology of such size as to preclude of their publication in the ordinary channels. The publication was placed in the charge of a temporary committee consisting of J. M. Aldrich, Nathan Banks, Morgan Hebard, E. P. Van Duzee and Alex. D. MacGillivray.

The following officers were elected for 1915:

President—Professor Lyman V. Kellogg, Leland Stanford Junior University.

First Vice-president—Professor James S. Hine, Ohio State University.

Second Vice-president—Mr. J. M. Aldrich, U. S. Bureau of Entomology.

Secretary-treasurer—Alex. D. MacGillivray, University of Illinois.

Additional Members of the Executive Committee—Mr. C. T. Brues, Bussey Institution; Professor William A. Riley, Cornell University; Professor T. D. A. Cockerell, University of Colorado; Mr. J. A. G. Rehn, Philadelphia Academy of Natural Sciences, and Professor A. L. Melander, Washington Agricultural College.

Member of Committee on Nomenclature—Nathan Banks, U. S. Bureau of Entomology.

The society decided to hold a summer meeting in August at San Francisco in affiliation with the American Association and the annual meeting in December at Columbus.

ALEX. D. MACGILLIVRAY,

Secretary

INDIANA ACADEMY OF SCIENCE

THE Indiana Academy of Science held its thirtieth annual meeting in Indianapolis, December 4-5. The attendance was the largest and the interest the greatest in many years. Over 100 new members were added to the roll this year. The following papers were presented:

"Science in Its Relation to Conservation of Human Life," address by the retiring president, Mr. Severance Burrage.

Symposium: Some Scientific and Practical Aspects of the Problem of Feeble-mindedness.

"The Feeble-minded Family," by Amos W. Butler.

"The Problem of Feeble-mindedness," by Dr. G. S. Bliss.

"The Feeble-minded and Delinquent Boy," by Dr. F. E. Paschal.

"The Feeble-minded and Delinquent Girl," by Dr. E. E. Jones.

"Feeble-mindedness in the Public School," by Miss Katrina Myers.

"The Alcohol Problem in the Light of Coniosis," by Robert Hessler.

- "Cold Storage, Practical Conservation," by H. E. Barnard.
- "Changing Conditions among the Cumberland Plateau Mountain People" (lantern), by Bernard H. Schockel.
- "The Conservation of Energy," by Arthur L. Foley.
- "Agriculture in Southern Indiana," by C. G. Phillips.
- "The Chief Reason for the Migration of Our Birds," by D. W. Dennis.
- "An Aeration Apparatus for Culture Solutions," with charts, by Paul Weatherwax.
- "Antagonism of *B. fluorescens* and *B. typhosus* in Culture," by F. A. Tetrault.
- "Notes on the Distribution of the Forest Trees of Indiana," by Stanley Coulter.
- "A New Enemy of the Black Locust," by Glenn Culbertson.
- "The Parasitic Fungi Attacking Forest Trees in Indiana," by Geo. N. Hoffer.
- "A New Disease of *Viola cucullata*" (lantern), by H. W. Anderson.
- "Oatsmut in Indiana," by F. J. Pipal.
- "Weed Seeds in Soil," by F. J. Pipal.
- "Additions to Indiana Flora," by Chas. C. Deam.
- "Some Peculiarities in *Spirogyra dubia*," by Paul Weatherwax.
- "Stomata of *Trillium nivale*," by F. M. Andrews.
- "Final Report on Cross Pollination of Corn," by M. L. Fisher.
- "The Primrose-leaved Violet in White County" (charts and specimens), by Louis F. Heimlich.
- "Continuous Rust Propagation without Sexual Reproduction," by C. A. Ludwig.
- "Correlation of Certain Long-cycled and Short-cycled Rusts," by H. C. Travelbee.
- "Some Species of Nannularia Common in Indiana," by C. E. O'Neal.
- "The Genus *Rosellinia* in Indiana," by Glenn B. Ramsey.
- "Cultivating and Breeding Medicinal Plants" (lantern), by Fred A. Miller.
- "Some Large Botanical Problems," by J. C. Arthur.
- "The Alba Gohre Collection of Birds' Eggs in the Museum of Purdue University," by Howard E. Enders.
- "A Study of the Maturation Period in the Mole-cricket" (blackboard), by F. Payne.
- "Note on a Peculiar Nesting Site of Chimney Swift," by Glenn Culbertson.
- "Mosaics in *Drosophila ampelophila*" (chart), by Horace M. Powell.
- "New Mutations in the Genus *Drosophila* and their Behavior in Heredity" (chart), by Roscoe B. Hyde.
- "Notes on Indiana Earthworms," by H. V. Heimburger.
- "Insects of the Between-tides Zone," by Chas. H. Arndt.
- "Regeneration in *Sagartia*," by D. W. Davis.
- "The Relation of Birds to Aquatic Life as Exemplified by Observation and Studies made at Lake Maxinkuckee," by Barton W. Evermann.
- "The Reptiles and Batrachians of the Lake Maxinkuckee Region," by Barton W. Evermann.
- "A Physical and Biological Survey of Lake Maxinkuckee," by Barton W. Evermann.
- "The Quantitative Determination of Copper," by W. M. Blanchard.
- "The Alundum Crucible as a Substitute for the Gooch Crucible," by George L. Clark.
- "Some Recent Work in Dairy Chemistry," by George Spitzer.
- "Analysis of Zirconium Minerals," by James Brown.
- "Correlation of High School and College Chemistry," James Brown.
- "Chemical Composition of Virgin and Cropped Indiana Soils," by S. D. Conner.
- "Sewage Disposal" (lantern), by Charles Brossmann.
- "Extension of Empirical Curve by the Addition of Estimated Values to a Series of Observations" (chart), by Albert Smith.
- "Tar-forming Temperatures of American Coals" (charts), by O. C. Berry.
- "Shawnee Mound, Tippecanoe County, A Glacial Alluvial Cone" (charts and photographs), by William A. McBeth.
- "Flood Prevention in Indiana," by W. H. Hatt.
- "Stratigraphic Correlation of the Outcrop at Spades, Indiana," by H. N. Coryell.
- "Pennsylvania Fossil Plants of the Bloomington Quadrangle," by J. F. Jackson.
- "Preliminary Geological History of Dearborn County," by A. J. Bigney.
- "Notes on the Cause of Asterism in 'Starolite'" (Asteriated Quartz) (charts and specimens), by J. W. Beede.
- "The Mississippian Section of Monroe County" (charts), by J. W. Beede.
- "The Flatwoods Region of Owen and Monroe Counties, Indiana," by Clyde A. Malott.
- "Mechanical Device for Testing Mercenne Numbers for Primes," by Thomas E. Mason.
- "Some Properties of Binomial Coefficients," by A. M. Kenyon.
- "The Watertown, S. D., Tornado of June 23, 1914," by J. Gladden Hutton.
- "A New Lantern and Projector" (lantern), by Arthur L. Foley.
- "Some Text-book Inconsistencies," by Arthur L. Foley.
- "The Mechanism of Light and Heat Radiations," by James E. Weyant.
- "A Simple Form for the Carey Foster Bridge" (lantern), by J. P. Naylor.
- "The Change of the Radioactivity of Certain Springs" (lantern), by R. R. Ramsey.
- "Radioactivity of Spring Water" (lantern), by R. R. Ramsey.
- "A Radioactive Electroscope" (lantern), by Edwin Morrison.
- "Some Results of the Indiana University Lake Survey," by Will Scott.
- "Report on Nett Lake," by A. B. Reagan.
- "Universal Cement Fence-Post," by F. W. Gottlieb.

A. J. BIGNEY,
Secretary

BEFORE AND AFTER LISTER¹

LECTURE I, "BEFORE LISTER"

On July 1, 1861, I entered the service of the State of Massachusetts as assistant surgeon of the Fifth Massachusetts, and on July 4 was sworn into the service of the United States in the shadow of yonder capitol. On August 1 I was honorably discharged and resumed my medical studies at the Jefferson Medical College. Strange as it now seems, when assistant surgeon I was not yet a graduate in medicine. As an evidence of the loose way in which medical and military matters were then conducted, I was actually appointed without any examination whatever.

After graduating in March, 1862, I again entered the service in May, after an examination, and was ordered to the Eckington Hospital in the then outskirts of Washington. Shortly afterwards I was ordered to fit up two churches as hospitals and to have them ready in five days. It was 5 P.M. on a Saturday afternoon.

People sometimes imagine that a practising physician can be transformed into an army surgeon merely by putting a uniform on him. I was not lacking in ordinary intelligence and was willing to work, but I was utterly without training. To get those two churches ready as hospitals I had to have beds, mattresses, sheets, pillow-cases, chairs, tables, kitchen utensils, knives, forks, spoons, peppers and salts, all sorts of crockery and other necessities for a dining-room, all the drugs, appliances and instruments needed for two hundred sick and wounded men; I needed orderlies, cooks and the endless odds and ends of things which go to make up a well-organized hospital. I did not know how to get a single one of these requisites. As to drugs, I did not know whether

¹ Two lectures before the U. S. Army Medical School, Washington, D. C., April 27 and 28, 1915.

to order six ounces or a gallon of laudanum, an ounce or two or a pound or two of opium, and I was in utter darkness as to the mode of getting any of the other things from a teaspoon to a cook. However, I inquired and as soon as I learned how, I set myself to work. For two nights I slept only about three hours each, and I had the satisfaction of reporting to Dr. Letterman at the end of three days, instead of five, that I was ready. On the fourth day I had one hundred wounded men in each hospital.²

I congratulate you in this more enlightened age and as students in this fine school where you are trained and drilled in matters which we had to cope with in our stumbling way, by dint of desperately hard work, without guidance, often learning only by our bitter mistakes.

We, the few surgeons still surviving those momentous four years, may well say to you *Morituri salutamur*.

I have been so very fortunate as to live during the whole period of the greatest revolution surgery has ever passed through. How strange seem these words of Erichsen, the then foremost London surgeon and Lister's early chief at University College Hospital uttered in 1874, just as surgery was on the eve of its very greatest triumph.

Surgery in its mechanical and manipulative processes, in its art in fact, is approaching, if it has not already attained to, something like finality of perfection.³

Anesthesia in 1846 and 1847 had robbed operations of the terror of agonizing pain. Quick, "slap-dash surgery"—a necessity before the days of anesthesia—then gave way to delicate, painstaking, artistic surgery. Antiseptics thirty years later relieved the patients from the terrors of death and gave to the surgeon restful nights and joyous days.

Hence when I received the kind invitation to address you it seemed to me that I could possibly render you some service by

² Keen, "Addresses and Other Papers," 1905, p. 424.

³ Wrench, "Lister's Life and Work," p. 281.

describing the state of surgery "Before and After Lister," since my testimony would be that of an eye witness.

When the Apostle Paul was about to be bound and scourged you remember that he claimed immunity as a Roman. "With a great sum obtained I this freedom," explained the chief captain. "But I," said the Apostle, with justifiable pride, "was free born." "With a great sum" of the most strenuous labor the men of my generation acquired the knowledge and the skill and the immense satisfaction of the antiseptic and aseptic era—but you, you are "free born" and have entered into a rightful heritage from your fathers. "Before Lister" and "After Lister" in the surgical calendar are the equivalents of "B.C." and "A.D." of our common chronology.

Modern military surgery may be said to begin with Ambroise Paré in the middle of the sixteenth century. Gunpowder, though long known, had been used in warfare to any large extent for only a few decades. The belief, shared fully by Paré himself, that such wounds were "poisoned," was universal. Treatment was directed to the destruction of the supposed poison by pouring boiling oil and hot pitch into such wounds. In the heat of his anger at the inhumanity of the new weapons he says in his preface to Book XI, "Of wounds made by gunshot and other fiery Engines and all sorts of Weapons":⁴

I think the deviser of this deadly Engin hath this for his recompence that his name should be hidden by the darkness of perpetual ignorance as not meriting for this his most pernicious Invention Any Mention from Posterity.

Yet with a curious inconsistency he immediately gives the name of a German monk as the "deviser."

⁴ "The Works of that Famous Chirurgion Ambrose Paré," translated by Th. Johnson, London, 1678, p. 270.

Listen to his quaint story of how he discovered that gunshot wounds were *not* poisoned. In 1536

it chanced on a time that by reason of the multitude that were hurt I wanted this Oil ["oyl of Elders Scalding hot with a little Treacle mixed therewith"]. Now because there were some few left to be dressed I was forced . . . that I might not leave them undrest to apply a digestive made of the yolk of an egg, Oil of Roses and Turpentine. I could not sleep all that night for I was troubled in mind, and the dressing of the precedent day (which I judged unfit), troubled my thoughts; and I feared that the next day I should find them dead, or at the point of death by the poison of the wounds. . . . Therefore I rose early in the morning. I visited my Patients and beyond expectation I found such as I had dressed with a digestive only, free from vehemency of pain, to have had a good rest and that their wounds were not inflamed . . . but . . . the others that were burnt with the Scalding Oyl were feverish tormented with much pain . . . and swoln. When I had many times tried this in divers others, I thought this much, that neither I nor any other should ever cauterize any wounded with Gunshot.⁵

But he still advocated the actual cautery for arresting hemorrhage even down to early in 1552. But later in that same year he changed his practise and thus describes his introduction of the ligature—a famous advance.

I confess here freely and with great regret that heretofore my practise has been entirely different from that which I describe at present after amputations. . . . I advise the young surgeon to abandon such cruelty and inhumanity and follow this better method. . . . Having several times seen the suture of veins and arteries for recent wounds which were attended by hemorrhage I have thought that it might be well to do the same after the amputation of a limb. Having consulted in reference to this matter with Etienne de la Rivière, Ordinary Surgeon to the King, and other surgeons sworn of Paris, and having declared my opinion to them, they advised that we should make the experiment [esspreuve] on the first patient that we had, but [note his cautious uncertainty] but we would have the cautery all ready in case of any

* Johnson's "Paré," p. 278.

failure of the ligature. I have done this on the person of a postillon named Pirou Garbier, whose right leg I cut off . . . following a fracture.⁶

At the Siege of Danvilliers' also in 1552 he records the amputation of the leg of a gentleman in the suite of M. de Rohan "without applying the actual cautery." In another place⁷ Paré says that he was taught this new method "by the special favor of the Sacred Deity." He also refers to Galen's advocacy of the ligature. After many trials, Paré definitely adopted the ligature and "bid eternal adieu to all hot Irons and Cauteries."

He does not seem to have lost sleep over the ligature as he did sixteen years before when he abandoned the boiling oil and the hot pitch. Both were experiments on human beings. "Human vivisection" would have been the outcry of a sixteenth-century antivivisection society. But had he or some successor *not* made these experiments we should still be filling gunshot wounds with boiling oil and hot pitch and searing amputation flaps with the actual cautery. How much greater a boon to humanity it would have been if years earlier instead of experimenting in both cases on human beings first, Paré had experimented on a few animals to determine whether gunshot wounds were poisoned and whether the ligature or the cautery *was* the best means of arresting hemorrhage.

We can also incidentally learn how the doctrine of euthanasia was applied in Paré's time in the case of the desperately wounded by the following incident.

In his first campaign, entering a stable where he expected to put up his own and his man's horses, Paré

* Malgaigne's "Paré," Chap. XXVI, pp. 227, 230.

⁷ Malgaigne's "Paré," III., 698.

⁸ Johnson's "Paré," London, 1678, Book XII, Chap. XXIV, p. 305.

found four dead soldiers and three propped against the wall, their features all changed, and they neither saw, heard nor spake, and their clothes were still smouldering where the gun-powder had burnt them. As I was looking at them with pity there came an old soldier who asked me if there was any way to cure them. I said no, and then he went up to them and cut their throats gently and without ill will toward them.⁹

Leaping over three and a half centuries of only moderate progress, let us next consider the state of surgery a hundred years ago. No better representative perhaps could be chosen than John Bell, the professor of surgery in Edinburgh, whose "Discourses on the Nature and Cure of Wounds" had reached a third edition in 1812, and his "Principles of Surgery" a new edition in 1826, to which his brother, Sir Charles Bell, also contributed.

In the former he states that tents or setons were much in use and the surgeons "were quite delighted with seeing prodigious quantities of matter spouting out when they drew their spigot away" (p. 299).

As to abdominal wounds he says:

Having put it down as a prognostic, which is but too well confirmed, by much melancholy experience, that wounds of the belly are mortal, there is no reason why we should, in recording our cases, take any note of a man having died after such a wound. Death from such a wound is a daily and expected occurrence and, therefore, is not marked; but if we find that a man has escaped, are we not to record every such escape? (p. 313).

Per contra, to-day recovery has been achieved after 19 wounds of the abdominal viscera!

He considers wounds of the joints also as mortal, and amputations even in the most favorable circumstances did not heal under four, five or six months!

In his "Principles of Surgery"¹⁰ he

⁹ Paget's "Ambroise Paré," p. 31.

¹⁰ John Bell's "Principles of Surgery," new edition, with comments by Charles Bell, London, 1826, p. 86.

pictures the wards of a hospital as follows: You look

upon limbs variously wounded, but all of them lying out, swollen, suppurating, fistulous, rotting in their own filth, having carious bones, bleeding arteries and a profusion of matter; the patients exhausted in the meanwhile, with diarrhea, fever and pain.

Again he refers to a wounded limb as "soaking in suppuration" and again, of its "lying in a slush of matter and foul poultices."

He relates the case of an officer under the care of Guérin, a French surgeon. He was wounded by a ball which had broken the fifth rib twice and traversed the entire chest. After dilating the wounds, Guérin introduced a seton ["a great strap of coarse linen"],

which, of course, went across the breast as a bow-string crosses a bow, and this seton he continued to draw with a perseverance which is truly wonderful from the first day to the thirty-eighth day of the wound; during all of which time the patient's sufferings were dreadful (p. 458).

In fifteen days the patient was bled twenty-six times. After the removal on the thirty-third day of a splinter of bone, which had been imbedded in the lung, the patient, strange to say, recovered both from the wound and from the surgeon. It is not to be wondered at that Bell condemns such treatment. But it existed in the practise of reputable surgeons.

Erysipelas, tetanus, pyemia, septicemia were rife. Hospital gangrene was endemic in many if not most hospitals, due to inevitable infection in practically every wound. Veritable epidemics were frequent. Is it any wonder that it had always been present for nearly two hundred years in the Hôtel Dieu in Paris when there were often from two to six patients (and such patients!) in one bed? Passing along the streets of Paris even during the Crimean War¹¹ "one could

¹¹ Wrench's "Life of Lord Lister," p. 239.

recognize at a distance a surgical hospital owing to the stench of the human putridity it contained." In the surgical wards, "no matter how well ventilated, there was a fetid sickening odor" up to the days of Lister himself, wrote Sir Hector Cameron, Lister's house surgeon in Glasgow. Death always stalked grimly behind the surgeon.

Secondary hemorrhage, tetanus, erysipelas, septicemia, pyemia and hospital gangrene were never all absent . . . and at times pyemia and hospital gangrene became alarmingly epidemic.¹²

After vividly describing the ravages of hospital gangrene Bell then vehemently asks:

What, then, is the surgeon to do? Is he to try experiments with ointments and plasters while the men are dying around him? Is he to seek for washes and dressings to cure such a disease as this? Is he to expend butts of wine contending, as it were, against the elements? No! Let him bear this always in mind, that no dressings have ever been found to stop this ulcer, that no quantities of wine or bark which a man can bear have ever retarded this gangrene; let him bear in mind that this is a hospital disease, that without the circle of the infected walls the men are safe; let him, therefore, hurry them out of this house of death; let him change the wards, let him take possession of some empty house and so carry his patients into good air; let him lay them in a schoolroom, a church, on a dunghill, or in a stable; let him carry them anywhere but to their graves.¹³

To-day we do not even know the bacteriology of this foul disease. I saw many cases of it during the Civil War, but since 1865 I have never seen a single case. There has been no opportunity to discover its germ if, as is probable, it is a germ disease. Lister made its return impossible.

But let us come down next to the period immediately before Lister's work.

You can not do better than read that remarkable and revolutionary paper entitled

¹² Cameron, *British Medical J.*, Dec. 13, 1902, p. 1844.

¹³ Bell, "Principles of Surgery," 1826, I., p. 149.

"Hospitalism" by Sir James Y. Simpson, of Edinburgh, published in 1867.¹⁴ It was a bombshell whose explosion aroused the profession as hardly any other paper in my lifetime. The controversy was bitter and widespread. Fortunately, antiseptics came close upon its heels and has forever done away with such a disgrace.

Simpson collected the statistics of the obstetrical mortality in hospitals and in homes with the following startling result.

Of 888,302 women delivered in hospitals, 30,394 died or 1 in 29—3.4 per cent.

Of 934,781 delivered at home, 4,045 died, or 1 in 232—0.47 per cent.

The reason for the greatly increased mortality in maternity hospitals—over seven times greater than in individual homes—was chiefly puerperal fever. After Oliver Wendell Holmes (1843) and Semmelweis (1861) had attacked the evil, Pasteur finally in 1879 showed its bacteriological cause and gave it the *coup de grâce*.

The 0.47 per cent. of Simpson's home cases has been reduced to 0.15 per cent. and even 0.08 per cent. in the maternity hospitals of to-day.

But his chief assault was upon the surgeons. He analyzed the four main amputations—arm, forearm, thigh and leg—and excluded amputations at joints and all the minor amputations (fingers, toes, etc.).

Of 2,089 such amputations in hospitals, 855 died, or 41 per cent.

Of 2,098 in country practice, 222 died, or 10.8 per cent.

The latter were collected from 374 country practitioners, thus eliminating the personal equation. The difference was clearly due to the crowding and lack of sanitation in the hospitals of that day.

He gives two very interesting tables. The first is most instructive in showing the

¹⁴ Simpson's Works, Vol. II., p. 345.

results in the then unsanitary state of all hospitals.

Mortality After the Four Selected Amputations in Proportion to the Number of Beds in the Hospitals

In the large Parisian hospitals	62 in 100 die
In British hospitals with 300 to 600 beds	41 in 100 die
In British hospitals with 300 to 201 beds	30 in 100 die
In British hospitals with 200 to 101 beds	23 in 100 die
In British hospitals with 100 to 26 beds	18 in 100 die
In British hospitals with 25 beds or less	14 in 100 die
In isolated rooms in country practise.	11 in 100 die

In the second he tabulates the mortality according to the experience of the operator.

Death Rate After the same Four Amputations in Accordance with the Experience of the 374 Operators

Those who had done less than 6 amputations	lost 1 in 7
Those who had done from 6 to 12 amputations	lost 1 in 9
Those who had done 12 or more amputations	lost 1 in 12

What an argument for the necessity for a year in a hospital for the recent graduate before allowing him full liberty of action!

In France matters were as bad if not even worse. T. Holmes and Bristowe in 1861 had found that in Paris, of 102 of the four amputations in question, 67 died, a mortality of 65.7 per cent., or two out of every three. Out of 1,656 amputations in the Paris hospitals collected by Malgaigne and Trélat 803 died, 48.5 per cent., almost one in every two (Simpson, p. 291).

To-day, how entirely changed is all this. Listerism has transformed what Bell well called "Houses of Death" into "Havens of Safety." No home, however wealthy its inmate, can be as sanitary, as surgically clean or give as good results as a modern hospital.

The best evidence of the truth of this statement I can give you is the statistics of Dr. W. L. Estes,¹⁵ of South Bethlehem, Pennsylvania. They are of especial value in that they are the statistics of the same surgeon in the same hospital and on the same class of patients. He reports the result in 724 major amputations. In 616 single amputations there were 28 deaths, a mortality rate of 4.54 per cent. Of 469 of the four selected amputations, 25 died, a mortality of 5.3 per cent. Of synchronous double, triple and one quadruple amputation, many of them complicated with other wounds and operations, there were 108, with 19 deaths, a mortality of only 18 per cent. It is very noticeable that in an earlier paper in 1894 in which he had reported the first 46 cases of synchronous double, triple and quadruple and complicated amputations, there were 13 deaths, 28.3 per cent., whereas from 1894 to 1913 in the last 62 such cases there were only six deaths, a mortality of 9.6 per cent., showing again the value of still larger experience even to an already experienced surgeon. In the second series there was no quadruple amputation.

But as officers of the Medical Corps of the Army you will be especially interested in the facts as to military surgery before and after Lister. Capt. Louis C. Duncan of our corps published a very interesting and comprehensive article¹⁶ just before the present European war broke out.

He states that in Motley's "Rise of the Dutch Republic" in three volumes covering "30 years of almost constant sanguinary warfare" in the sixteenth century he "never once alludes to an army surgeon or an army hospital"! The surgeons were undoubtedly not officially attached to the army, but were in the suites of kings,

¹⁵ *Annals of Surgery*, July, 1913.

¹⁶ *Journal of the Military Service Institutions of the United States*, March-April, 1914.

princes or great nobles, as was Paré, in the same century.

To Sir James McGrigor in the Peninsular Campaign (1808-11) only fifty years before our Civil War, is given the credit by Duncan of first collecting accurate military medical statistics.

One hundred and fifty years ago 25 per cent. or more of the wounded died. In the Civil War and in the Franco-Prussian War of 1870-1 the rate had fallen to about 15 per cent., while to-day up to the present war not over 5 or 6 per cent. die of wounds.

The Crimean War will always be an example of utter inefficiency in the English and even worse in the French army. Its one bright spot is the splendid epoch-making work of a woman, Florence Nightingale, whose labors were unceasing and effective. Every war since then has seen less sickness and fewer deaths because of what she then accomplished.

Chenu, the French medical historian of that war, has made one curious and interesting calculation, partly official, partly estimated. The number of projectiles of all kinds actually fired he gives as 89,595,363. The total number of killed and wounded was 175,057. This would show that it took 512 projectiles to kill or wound one man. Such a disproportion would more than justify a cartoon during our Civil War. Two soldiers were surprised by a hundred of the enemy. One proposed to the other to run for it. "No," was the cool reply, "There's no danger, for they say only one ball in 200 ever hits and there are only one hundred of those fellows."

Duncan's figures give 82,901 British soldiers sent to the Crimea, but the average strength was only 34,559, or only about 40 per cent., of effectives. The killed (2,755) and the deaths from wounds (2,019) gave a battle death rate of 69 per 1,000 per annum, while the disease death rate rose to 230 per 1,000 per annum.

In all, 300 men out of each 1,000 perished each year!

But the French statistics are still worse. While 315,000 were sent out, the average strength was less than 104,000 effectives, or only 33 per cent. The killed numbered 7,607 and the deaths from wounds 8,813. The battle death rate was 70, the disease death rate 341, per 1,000 per annum. Over 6,000 died from typhus alone.

Could there be a nobler example of the altruism of our profession—an altruism often tested and never in vain—than that shown by Drs. Richard P. Strong, Thomas W. Jackson, and many other doctors and trained nurses, and now finally by the chief of our corps—the friend of humanity—Major General William C. Gorgas in hastening, regardless of danger, to the relief of Serbia, sorely smitten by the deadly typhus fever?

Chenu's report gives a summary of the English as well as the French losses. Comparing it with Simpson's civil statistics eleven years later the mortality of the four selected amputations (arm, forearm, thigh and leg) was as follows: Of 2,089 of these four amputations in civil hospitals the mortality in Simpson's table was 41 per cent. In the Crimean War among the British there were 460 such amputations and 183 deaths, or 40 per cent. In the French army there were 5,972 such amputations with 4,023 deaths, a mortality of 67.4 per cent. In both armies disarticulation at the hip-joint had a mortality of 100 per cent., *i. e.*, every case died. It is instructive also to compare the fate of those who had an amputation of the thigh (1,666 French cases) with a mortality of 92 per cent., and 487 cases treated conservatively, *i. e.*, without amputation, with a mortality of only 70 per cent.!

In our Civil War Duncan quotes the figures of Fox, which are "the latest revised

statistics and are all larger than those of the Medical and Surgical History of the War." The average strength of the Union Armies was 806,755, and the deaths 359,528, of whom 67,058 were killed in battle and 43,012 died of wounds. This gives a battle death rate of 33 per 1,000 per annum. The disease death rate was 65 per 1,000 per annum. The case death rate from disease was only 3.4 per cent., a very low figure.

I can testify to the excellent condition of the Civil War hospitals, of which I saw many, but only in the East. When I say "excellent condition" it must be with the reserve that we knew nothing as to bacteriology, which did not exist, nor of infection, which was utterly unknown as to its causes and prevention. The general sanitary conditions, and by this I mean shelter, ventilation, cleanliness, good food, as good nursing as intelligent orderlies could give, etc., were all excellent. But the surgical conditions as we now know were simply dreadful. Practically every wound suppurated, and in summer I have seen many wounds swarming with squirming maggots as large as chestnut worms—disgusting, but, fortunately, not especially dangerous.

In my "Surgical Reminiscences of the Civil War"¹⁷ I have given many statistics taken from the official Medical and Surgical History of the War, a few of which I will reproduce that you may see what blessed conditions you "free born" men have inherited. Pyemia (blood-poisoning) was one of our worst scourges. There were 2,818 cases, and of these only 71 recovered, a death rate of 97.4 per cent. Few of you probably have seen even one such case. I have given a matter-of-fact description of it in my "Surgical Reminiscences," but if you wish to see it sketched by a master's

hand read that most touching and beautiful of all medical stories I know—"Rab and his Friends," by dear old Dr. John Brown, of Edinburgh. He vividly paints the sudden change in the wound, the pulse, the eye, the mind, on and on, worse and worse, until "*that animula, blandula, vagula, hospes comesque* was about to flee."

Tetanus had a mortality of 89.3 per cent. Of amputations at the hip-joint 83.3 per cent. died. Trephining had a mortality of 61 per cent. Even of ligations of the femoral artery, 374 in number, 281 died, or over 75 per cent. Of 2,235 cases of secondary hemorrhage, 61.7 per cent. died. Hospital gangrene, of which there were several hundred cases, had only a mortality of about 25 per cent., because we early learned the correct though empirical treatment, viz., the application of the actual cautery, pure bromine, strong nitric acid or similar destructive agents which killed the germ, whatever it was, and arrested the disease.

The Franco-Prussian War of 1870-71 was marked by notable progress in military sanitation in the German army, yet in spite of this there were 74,205 cases of typhoid fever, almost 10 per cent. of the entire average strength (788,213) and 8,904 deaths, a mortality of 11.3 per cent.

Surgically the results were nothing to boast of. Listerism had as yet made but little progress in the profession. Carbolic acid was used to some extent, but there was no thorough antiseptic system, for the germ theory was as yet neither understood nor accepted.

Of tetanus there were 294 cases, and 268 died, a mortality of 91.1 per cent.

The total of the four selected amputations was 2,194 with 1,196 deaths, a mortality of 54.5 per cent.—over one half.

Disarticulation at joints showed an average mortality of 56 per cent. Fifteen

¹⁷ Keen, "Addresses and Other Papers," 1905, p. 420.

amputations at the hip-joint gave a mortality of 100 per cent., and resections claimed 40.2 per cent. of deaths. Even at the knee-joint Stromeyer amputated 36 times with 36 deaths and Nussbaum 34 times with 34 deaths.¹⁸

The French results were naturally worse, for their armies were constantly being defeated and retreating, and, especially in the latter part of the war, they consisted largely of volunteers, while the Germans were mostly veterans of the Schleswig-Holstein and Austro-Prussian wars.

Of the Boer War (1899-1901) only two features need be noticed. First, that typhoid attacked 57,684 men and killed 8,022, while the Boers only killed 7,781. Bacteria were more deadly than bullets, as Osler has said.

Secondly, the modern missile was for the first time in general use, with the result that instead of about 15 per cent. of the wounded losing their lives, only about 8.8 per cent. died. The wounds from the new missile were much less severe and healed more quickly than ever before. The first aid packet also had come to the aid of the soldier.

The Spanish American War, surgically speaking, was of little moment, as the numbers killed and wounded were too small to make the statistics of any great value, but it is gratifying to find that only 4.6 per cent. of the wounded died.

Typhoid, however, held high carnival. It caused 86.24 per cent. of all the deaths! Happily we can say that hereafter—thanks chiefly to the anti-typhoid inoculations—there will never be another such holocaust. (*Vide* Lecture II.)

The statistics of the Russo-Japanese War also need detain us for only a moment. I shall only quote the Japanese official statistics, as given by Major Lynch, of our

army.¹⁹ There were 47,387 killed. Of 173,425 wounded 11,500 died, a mortality of 6.7 per cent. The killed and those who died of wounds numbered in all 58,887, while the deaths from disease numbered only 27,158, a remarkable showing.

The present war naturally has yielded so far very few statistics. These can only be collected and tabulated after some years of peace. So far as I can judge, I fear that, while the mortality from disease (except perhaps from typhus, especially in Serbia) will be less than in former wars, the military conditions are such that the larger number of artillery wounds, the unavoidable delay in gathering the wounded into hospitals, the apparent absence of any truce for collecting the wounded and burying the dead, and the virulent infection from the soil may result in a large mortality rate and possibly a larger percentage than in previous wars in spite of the benefits of Listerism. But were the first-aid packet and the Listerian treatment not available the mortality ratio in this present horrible war unquestionably would be far greater than that which will be recorded.

This short résumé gives us some idea of surgical conditions preceding the great revolution inaugurated by Lister to which we will next proceed.

W. W. KEEN

LADY HUGGINS

LADY MARGARET LINDSAY HUGGINS, who passed into the higher life March 24, was a personality worthy to be classed with the group of pioneer women of the last century who, under difficulties, achieved distinction in intellectual fields.

Mary Somerville was deprived of her candle when her mother found that she was secretly studying Euclid; Anna Swanwick was denied

¹⁹ "Reports of Military Observers attached to the Armies in Manchuria during the Russo-Japanese War," Part IV., p. 399.

by her father any teaching in Greek as out of all propriety for girls; Agnes Clerke when a young girl could get no one to tell her about the stars, neither could Margaret Lindsay Murray, but they all struggled against odds and reached the goal of knowledge. Lady Huggins in a letter speaking of the death of Miss Swanwick, the distinguished translator of the tragedies of *Æschylus*, remarked:

It is curious to me to notice what seems an inferiority in some very important ways among the young women coming on, who have had every possible educational advantage, when I compare them with such women as Anna Swanwick, who had to struggle for her education. I think perhaps everything at present tends to be made too easy. The present generation have more knowledge, I know, and they ought to do more; will they?

Lady Huggins said she was born a lover of the stars. Before she reached her teens she worked with a little telescope making drawings of the constellations and sunspots. Later, inspired by anonymous articles in the magazine, *Good Words*, she became interested in the spectrum, and made a little spectroscope for herself by which she detected the Fraunhofer lines. It was the romance of her life that she afterwards became the wife of the astronomer who wrote the papers, and with him made many discoveries with the magic instrument. The *London Times* in its notice of Lady Huggins remarks that Richard Proctor called Huggins the "Herschel of the Spectroscope" and that his wife was to him what Caroline Herschel had been to her brother, an unwearied coworker.

She took upon herself to guide the telescope for the long-exposure photographs of the spectra of stars, she developed the plates with great skill, and her husband remarked on the keenness of her eye and judgment in arranging the plates in sequences representing stellar development.

The quest for knowledge of this pair was unremitting. Their absence from a notable scientific gathering in London was once noted, when she remarked:

Astronomy is a heartbreaking science in England. We rarely go anywhere in the evening but

wait for breaks in the clouds. We discover something which seems to be a clue to further knowledge and wish to pursue it; night after night the clouds disappoint us and sometimes we have to wait a year to take up that clue again.

Lady Huggins constantly shared the excitement of her husband in the early days of astrophysics when, as he said, "every observation revealed a new fact and almost every night's work was red-lettered by some discovery." She once remarked to a visitor passing in her laboratory a tray in which a fresh print was being washed:

There is a bomb to be thrown into the astronomers' camp. It will be harmless, but effective.

Her name appears as joint author of ten of the scientific papers of the second volume of *Tulse Hill Publications*, and as joint editor of all. Of the epoch-making first volume, "The Atlas of Representative Stellar Spectra," she is joint author. These two and a third volume, entitled "The Royal Society," containing the addresses delivered by Sir William as president, are superb specimens of book-making, perfect in type work, illustration and binding, and this achieved by the taste and skill of Lady Huggins.

The great delight of her vacations was to unearth strange old astronomical drawings and reproduce them in India ink for the initial letters of the chapters of her books, or to make sketches in water-colors or by etching. An appreciation in an English paper remarks:

Lady Huggins's striking and attractive personality expressed itself in her appearance and manner. There was in her not only the conscientiousness, thoroughness and care which should be the characteristic of the scientist, but also the imagination and love of beauty which distinguish the artistic temperament.

She published a paper on an astrolabe of rare workmanship, which appealed to her not only for its astronomical association, but for its "charm," as she expressed it.

Lady Huggins was greatly interested in the educational and scientific developments in the New World and especially in the "educational justice" now given women there. Entirely on her own initiative she presented to Wellesley

College Observatory some of her personal astronomical treasures, including stained glass panels once in the Tulsa Hill home. Further bequests to Wellesley College are found in her will. In a letter written in her extreme illness, stating her decision to make this gift, occurs a passage which shows her vision of what America and the students of the American colleges ought to be and do.

The first sentence refers to the superb carrying out of the fire drill, which saved so many lives in the great fire of a year ago at Wellesley, and the energy and devotion of the alumnae which raised the three million restoration and endowment fund. She says:

I rejoice over the splendid spirit shown by the old Wellesleyans! I believe in the real great America! I believe in Wellesley College, one of its far-seeing creations! It is to such colleges for the training of young life to create the New Heaven and New Earth to which we all look forward.

SARAH F. WHITING

WHITING OBSERVATORY,
WELLESLEY COLLEGE

THE UNIVERSITY OF MINNESOTA AND THE MAYO FOUNDATION

THE executive committee of the board of regents of the University of Minnesota has prepared a report in which it recommends that the university establish graduate work at Rochester, Minnesota, that such work be directed by the graduate school through its dean and the medical school graduate committee, that professors and other teachers be appointed on the nomination of the same committee, to carry on graduate teaching and research at Rochester, and that the offer of clinical and other facilities and gifts made by the Mayo Foundation be accepted.

The terms of the agreement are to be as follows:

1. The agreement is made between William J. Mayo and Charles H. Mayo as founders; the Mayo Foundation; Burt W. Eaton, George W. Granger and Harry J. Harwick, trustees of the \$1,500,000; and the university. It sets forth copies of the articles of the foundation and of the two trust agreements and asserts or provides:

2. That the Mayos and their associates have entered into an agreement with the foundation for the period of six years after September 1, 1915, to pay all moneys and provide all subjects, facilities and material necessary to enable the foundation to carry out its agreement with the university.

3. That the board of regents is by law required to manage the university and appoint its professors and employees and fix their salaries and may accept in trust gifts and bequests upon the terms and conditions on which they are granted.

4. That the university is maintaining a medical school and is carrying on graduate medical and surgical instruction and has determined to increase its faculty, secure additional facilities, sites and material, appoint additional professors and assistants and carry on part of the work of the school of medicine at Rochester.

5. That the foundation gives and grants to the university free of charge the right to use for medical and surgical education and research space and rooms and equipment in a certain building in Rochester, together with all clinical and other materials and opportunities for graduate medical and surgical work available at the Mayo Clinic, St. Mary's Hospital, the Kahler Sanatorium and the Colonial Sanatorium in Rochester, for a period of six years after September 1, 1915.

6. That the foundation also agrees during that period to pay all salaries fixed by the board of regents and payable to professors, assistant professors and instructors appointed by the board.

7. That until September 1, 1921, the net income of each of the trust funds shall remain in the hands of the trustees as an added increment to the principal of the funds.

8. That from and after September 1, 1921, the principal of the funds and all accumulations to that date shall be turned over to and become the property of the university.

9. That the funds and the income therefrom are granted in trust to be used by the university as follows: (a) The principal shall always be kept intact by the board of regents and be

invested in suitable securities; (b) The income from the funds shall be used for the purpose of graduate medical and surgical instruction and research carried on under the direction of the board of regents at Rochester, Minn., with the understanding that appropriations may be made for carrying on medical investigations anywhere within or outside the state of Minnesota.

10. That the agreement may be terminated at any time on or before September 1, 1921, upon one year's notice given by either of the parties to the other, subject to the cooperation of all parties to discharge to the satisfaction of the university outstanding obligations to graduate students.

11. That the university accepts the gifts and grants, and obligates itself annually to furnish to the foundation until September 1, 1921, a budget stating the needs of this branch of the work at Rochester.

CONDITIONS AT THE UNIVERSITY OF UTAH

THE committee of inquiry of the American Association of University Professors, appointed to report upon conditions at the University of Utah which have led to the resignation of seventeen members of the university faculty, has made a preliminary report. Its findings are concurred in by all the members of the committee who have been able to examine the evidence, who are: E. R. A. Seligman, chairman, Columbia University; John Dewey, Columbia University; Frank Fetter, Princeton University; J. P. Lichtenberger, University of Pennsylvania; A. O. Lovejoy, Johns Hopkins University; H. C. Warren, Princeton University.

The report is printed in full in *The Nation* and in *School and Society*. Of the eight findings of the committee three are as follows:

I. With regard to the nature of the grounds given by the president as his reasons for recommending the dismissal of certain professors on March 17 last, the committee finds as follows: (1) Of the four charges brought against these professors, two specify acts—namely (a) uttering in a private conversation with a colleague an unfavorable opinion of the chairman of the board of

regents, and (b) speaking, in private conversation, in "a very uncomplimentary way of the university administration"—which are not proper grounds for the dismissal of university teachers. (2) The president of the university and the chairman of the board of regents, by sanctioning the recent action and publication of the board, virtually gave notice that the expression by a professor, in private conversation, of an unfavorable judgment of their qualifications for office would be a ground for dismissal. This attitude, unjustifiable in general, the committee regards as especially unsuitable in officials of a state university.

IV. One of the causes of the resignation of members of the university faculty was the existence of conditions before March 17, such that the faculty had no proper means of bringing its views on university matters—when its views differed from those of the president—to the notice of the governing body. It was, in the opinion of the resigning professors, partly in consequence of these conditions that the board, on March 17, took action which those professors regarded as unjust to individuals and injurious to the interests of the university. Since the resignations, the board has adopted radical and excellently conceived alterations in the plan of administration of the university; these changes should give the University of Utah an exceptionally advanced position among American colleges, in respect to provision for consultation between faculty and trustees. The committee hopes that great good will result from these modifications of the university's administrative machinery; it feels constrained, however, to reserve final judgment as to the actual effect of the plans until their working under local conditions has been tested by experience. The committee deeply regrets that the board has refused to apply its new procedure at once to the cases which have recently come before it. The committee deems itself bound, in simple justice, to note that the credit for whatever benefits may accrue to the university from the reforms mentioned, must be given primarily to the professors who by their resignations made effective protest against the antecedent conditions certain of which these reforms are designed to correct.

VIII. One of the gravest and most regrettable features of the crisis at this university, in the committee's opinion, is the attitude still maintained by the board of regents towards numerous petitions asking for a thorough public investigation of the recent incidents and of general university conditions. These petitions, which have come

from the faculty, the alumni association, the students, and a large number of citizens of the state of Utah, the board has in all cases rejected, declaring that it alone is responsible for the management of the university, that it has no doubts as to the correctness of its past action and the rectitude of its own motives and those of the president, and that it therefore can not permit its action to be influenced by protests coming from others. This position seems to the committee to show that the board fails to understand, or at least to act upon, three fundamental facts: namely, that every institution of public education, and especially a state university, requires for its success the confidence and respect of the public; that there can be no sure hold upon public confidence without an unflinching readiness to face publicity in regard to all official acts and policies; and that the only effective way in which any public body can meet serious charges brought by responsible persons is by not merely permitting, but demanding a searching and open inquiry into its methods. The committee gathers that the attitude taken by the board has aroused on the part of a large section of the local public, including a majority of the alumni and of the students, a degree of suspicion, and even hostility, which must be a continuing detriment to the university's efficiency as an instrument of public education, and must affect disadvantageously the position and the work of teachers in the institution.

THE PACIFIC DIVISION OF THE AMERICAN ASSOCIATION

At a recent meeting of the Pacific Coast Committee of the American Association for the Advancement of Science, the first executive committee of the Pacific Division was elected in accordance with the provisions of the constitution of the division. The officers of the division have been elected by the executive committee. The result of these elections is as follows:

President: Dr. W. W. Campbell, Lick Observatory, Mt. Hamilton.

Vice-president: Dr. D. T. MacDougal, Carnegie Desert Laboratory, Tucson.

Secretary-Treasurer: Albert L. Barrows, University of California.

Executive Committee: Theodore C. Frye, University of Washington; Edward C. Franklin, Stanford University; C. E. Grunsky, San Francisco;

George E. Hale, Mt. Wilson Solar Observatory, Pasadena; Vernon L. Kellogg, Stanford University; Andrew C. Lawson, University of California; E. Percival Lewis, University of California.

The Pacific Division is now supported by about one thousand of the members of the American Association resident within the region and by affiliations with twelve local scientific societies. After the San Francisco meeting of the American Association during the first week of next August, the recently elected officers of the division will carry on the work of the association on the Pacific coast which up to this time has been conducted by the Pacific Coast Committee. The first meeting of the Pacific Division will be held in the spring of 1916.

SCIENTIFIC NOTES AND NEWS

COLUMBIA UNIVERSITY has conferred its doctorate of science on Robert S. Griffin, rear-admiral and engineer-in-chief, U. S. Navy, and Arthur L. Day, director of the geophysical laboratory, Carnegie Institution of Washington.

THE Stevens Institute of Technology has conferred the degree of doctor of science on Otto H. Tittmann, for many years superintendent of the United States Coast and Geodetic Survey.

DR. V. G. HEISER has resigned as director of health in the Philippines, to accept the position of director for the Orient of the work of the Rockefeller Foundation.

DR. RICHARD H. CREEL, of the Federal Health Bureau, has declined the offer of the post of health commissioner of Boston.

DR. ELWOOD MEAD, who has accepted a call to the newly established professorship of rural institutions in the University of California, has been appointed by Secretary Lane chairman of a central board of review of the committees on revision of reclamation project costs.

A TESTIMONIAL dinner was tendered to Dr. Leo Loeb at the University Club, St. Louis, on May 25, by members of the medical profession of St. Louis, the scientific faculties

of Washington University and St. Louis University and members of the Biological Society of St. Louis.

A TESTIMONIAL dinner to Henry Smith Munroe, professor of mining in Columbia University, 1877-1915, was given by his old students in the schools of mines, engineering and chemistry at the Chemists' Club, New York, on May 28. The special occasion for this was the approaching retirement of Professor Munroe at the close of the present collegiate year. Professor Munroe, who is the senior member of the faculty, will then have completed thirty-eight years of service. The speaking following the dinner was begun by R. V. Norris, president of the Alumni Association, who introduced Professor J. F. Kemp as toastmaster. The other speakers were President Nicholas Murray Butler for the university; Thomas Haight Leggett for the American Institute of Mining Engineers; Walter Renton Ingalls for the Mining and Metallurgical Society of America, and John Parke Channing for the alumni. In concluding his remarks, Mr. Channing presented to Professor Munroe, on behalf of his former students, a massive bronze—the Sluice-Miner—by Louis Potter. To these speeches Professor Munroe replied.

The Alpha Chapter of the Society of Sigma Xi has elected the following officers for 1915-1916: *President*, J. G. Needham; *Vice-president*, F. K. Richtmeyer; *Recording Secretary*, J. G. Pertach; *Corresponding Secretary*, James McMahon; *Treasurer*, O. A. Johannsen.

At the annual meeting of the Yale Chapter of Sigma Xi, Professor L. L. Woodruff was elected president and Dr. H. L. Seward vice-president. Professor R. S. Lull will give the address at the joint commencement meeting of Sigma Xi and Phi Beta Kappa at Yale.

DR. JAMES W. JOBLING, of the Vanderbilt School of Medicine, Nashville, Tenn., was elected president of the American Association of Immunologists at its recent Washington meeting.

PROFESSOR ALFRED DACHNOWSKI, in charge of plant physiology and ecology at Ohio State

University, has accepted a position in the bureau of plant industry, U. S. Department of Agriculture. He will continue his investigations upon peat soils and their agricultural utilization.

MR. G. L. FAWCETT, plant pathologist of the Porto Rico Experiment Station at Mayaguez, resigned in February and has gone to Argentina, where he has accepted a position as plant pathologist of the Experiment Station at Tucuman.

MR. LOUIS G. SCHULTZ, director of the Argentine Central Magnetic Observatory at Pilar, since its foundation in 1903, has recently resigned and returned to the United States.

POUL LINDHOLM, engineer of highways, Copenhagen, Denmark, has been awarded the traveling fellowship of the American Scandinavian Foundation for 1915-16. He will devote the year to graduate work in highway engineering at Columbia University.

PROFESSOR HANS LUDENDORFF has been appointed head observer in the Astrophysical Observatory at Potsdam.

DR. R. TAIT MCKENZIE, director of the department of physical education at the University of Pennsylvania, sailed on May 29, for London, where he will take charge of the new physical department established by the British government to care for the health of recruits.

PROFESSOR JOHN M. COULTER, of the University of Chicago, will give two courses of lectures in the University of California during their summer session, which begins on June 21. One of them is an elementary course in evolution and heredity; the other is an advanced course in the evolution of sex in plants.

PROFESSOR GRAHAM J. MITCHELL, of the department of geology of the University of Oregon, will spend the coming summer in Curry County with Professor B. S. Butler, of the school of mines of the Oregon Agricultural College. Professor Warren D. Smith, head of the department of geology of the University of Oregon, will spend a part of

the summer studying the stratigraphy of the western slope of the Cascades. Both of these pieces of work will be carried on for the Oregon Bureau of Mines and Geology. During three weeks of the summer between July 12 and August 1, Professor Smith in cooperation with Professor Sweetser, of the botany department, University of Oregon, will conduct a field class to Crater Lake.

PROFESSOR JOHN H. SCHAFFNER, of the Ohio State University, will spend two months this summer in Kansas, Arizona and California, making a detailed study of the conifers of North America.

DR. W. RALPH JONES, scientific assistant in plant pathology in the office of Fruit Disease Investigations, of the U. S. Department of Agriculture, died on May 17, in the thirty-second year of his age. Dr. Jones was a graduate of Johns Hopkins University and had been engaged in the study of small-fruit diseases for several years.

DR. SAMUEL BALDWIN WARD, since 1884 dean of the Albany Medical College and professor of the theory and practice of medicine, died on June 3 at the age of seventy-three years. He was graduated from Columbia University in 1861 and from the medical department of Georgetown University in 1864. From 1867 to 1869 Dr. Ward was curator of the medical museum of Columbia University. He was professor of anatomy at the Woman's Medical College of the New York Infirmary from 1867 to 1870, and of surgery from 1870 to 1876. From 1876 to 1884 he was professor of surgical pathology at the Albany Medical College.

MANY American men of science, especially the geologists who participated in the Gaspé excursion of the Twelfth International Geological Congress, 1913, will learn with regret of the recent death at Gaspé, of Commander William Wakeham, Dominion inspector of marine fisheries in the Lower River and Gulf of St. Lawrence. Commander Wakeham was the courteous and delightful host on this occasion, of the geological party on board his cruiser *Princess* in a trip down Gaspé Bay. Dr. Wakeham's entire professional life was

spent on that coast, first as physician, then as magistrate and inspector of fisheries for the Quebec coast, and subsequently as His Majesty's commissioner for the preservation of the fisheries in Canadian Atlantic waters. He attained distinction for his intimate knowledge of fish, fish breeding and fisheries procedures and was recognized as a leading authority in these fields, while his long life and intimate concern with all the activities of the coast made him the most influential and most widely informed personality of the Gaspé country.

AMONG the passengers on the *Lusitania* was James Blaine Miller, of the Coast and Geodetic Survey. No information in regard to him has been received and there is practically no doubt that he went down with the vessel. James Blaine Miller was born in Erie County, Pennsylvania, October 30, 1883. He graduated from Oberlin College, Ohio, in June, 1903, with the degree of bachelor of arts. He was appointed an aid in the survey June 18, 1903, was promoted to assistant September 1, 1906, and during his twelve years of service was employed chiefly on hydrographic and leveling work in various localities. In 1904 he was engaged in surveys in Porto Rico. In 1906 he was in command of the steamer *Endeavor* in the survey of Chesapeake Bay; in 1906 he was placed in command of the steamer *Research* in the Philippine Islands; in 1909 he was transferred to the command of the *Fathomer*; in 1911 he returned to the United States and in the fall of that year he was placed in command of the steamer *Patterson* for surveying work in the Hawaiian Islands and on the coast of Alaska. He was detached from the command of the *Patterson* in March of the present year, and had been granted leave for several months to take a trip abroad.

SCIENCE of June 4 mentions the death in the European war of Joseph Déchelette and Captain M. Bournon, both of whom have made valuable contributions to French archeology. The last number of *L'Anthropologie* adds to these Captain René Avelot, known for his contributions to geography and especially those dealing with the ancient populations of cen-

tral and eastern Africa; and Captain Maurice Cortier, an eminent topographer, active in archeology in the territory of Sahara.

SM ARTHUR HERBERT CHURCH, formerly professor of chemistry at the Royal Academy of Arts, London, known for his contributions to chemistry and mineralogy, has died at the age of eighty-one years.

DR. ERNST MEUMANN, professor of psychology at Hamburg, known for his contributions to experimental and educational psychology, has died at the age of fifty-three years.

THE death is also announced of Dr. Stefan Witasek, director of the psychological laboratory at Gratz, at the age of forty-five years.

DR. OSKAR SIMONY, emeritus professor of mathematics and physics in the Agricultural School at Vienna, has died at the age of sixty-three years.

THE Brooklyn Botanic Garden was opened on June 5 for inspection by its members and invited friends and, on the following day, it was opened to the general public, and will remain open, free to all, daily hereafter.

THE third annual meeting of the American Association of Anesthetists will be held in the New Auditorium, San Francisco, on June 21, under the presidency of Dr. Charles K. Teter, of Cleveland. There will be two scientific sessions, the first item on the program being the address of the president, who will speak on the subject "Nitrous Oxide Oxygen Anesthesia in Obstetrics."

THERE has been founded by the graduate and undergraduate students of the department of geology and mining of the University of Kansas a professional fraternity, Sigma Gamma Epsilon. It is proposed to establish chapters of the organization in the leading educational institutions of the United States and Canada. At present there does not appear to be any such fraternity and it is hoped that its organization will promote an increased interest in geological science.

At the election of members to the Society of the Sigma Xi held recently by the Omega Chapter of the Ohio State University the following candidates were chosen: Professor J.

Warren Smith, professor of meteorology from the faculty; seventeen young men and two young women from the graduate school and fourteen young men from the fourth year or senior class. This is the largest number ever elected by the Omega chapter. The greater increase is from the graduate school, as candidates from this class are not eligible unless they have done creditable research work as well as shown an inclination and ability to continue such work.

THE newly established chapter of Sigma Xi was installed at the University of Texas on the evening of May 17. The installation exercises were conducted by Professor S. W. Williston of the University of Chicago. Professor Williston gave an interesting public lecture on "The Contribution of Texas to our Knowledge of Early Land Life." Following the lecture the installation proper took place at the university club house in the presence of the charter members, initiates and invited guests. The chapter consists of twenty-one charter members and eleven newly elected members. The following are charter members: C. L. Baker, E. C. H. Bantel, S. L. Brown, J. M. Bryant, H. P. Bybee, D. B. Castool, E. L. Dodd, W. S. Hunter, D. J. Jones, T. L. Kelley, J. M. Kuehne, I. M. Lewis, F. McAllister, J. T. Patterson, M. B. Porter, A. Richards, E. P. Schoch, F. W. Simonds, F. L. Whitney, C. S. Yoakum and M. S. Young. The newly elected members are: F. D. Barrow, Mrs. L. T. Binkley, A. Deussen, W. A. Felsing, O. G. Hartman, Miss Goldie Horton, W. T. Read, E. W. Schuhmann, B. C. Tharp, T. U. Taylor and J. A. Udden. The following officers have been elected for the coming year: :

President: Professor J. T. Patterson.

Vice-president: Professor F. W. Simonds.

Recording Secretary: Professor E. L. Dodd.

Corresponding Secretary: Professor I. M. Lewis.

Treasurer: Professor S. L. Brown.

MT. LASSEN, California, whose violent eruption of May 19 places it in the first rank of volcanoes now dangerously active, has become the subject of an informal cooperative study by the geological survey and the forest service. At the request of the survey, a tele-

gram has been sent from Washington instructing the officers of the Lassen national forest, in which the peak stands, to continue observations of the volcano's activity and keep a record to be used as a basis for a scientific investigation by J. S. Diller, the government geologist, who is expected at Lassen early in July. The observations are being made by forest rangers at the scene and from a fire lookout tower on Brokeoff Mountain, a few miles north of the crater, where the forest service last year kept watch on the numerous eruptions which occurred from May to September. It is not known whether a cloudburst started the last eruption by precipitating rain down upon the molten lava in the crater, or whether melting of the snow on the peak, with consequent flowing of water into the crater, caused the accumulation of steam which blew a river of mud out of the mountain. Mr. Diller, who made a study of the volcano last year, said that he inclined toward the melted snow theory, adding that the bright glow reported as appearing on the clouds of smoke and steam over the crater is a reflection of the red-hot matter uncovered by the eruption, indicating that the volcano is in a more or less dangerous mood. The river of mud which was shot out of the north side of the crater and down Hat Creek has damaged government and private property, destroying bridges which were necessary to permit the entrance of livestock that are grazed on the forest range during the summer. Some 12,000 cattle and 30,000 sheep are grazed on the Lassen forest every year.

SPECIAL arrangements have been made for the members of the Geological Society of America and of the Association of American Geographers attending their summer meetings and the sessions of the American Association for the Advancement of Science at San Francisco beginning August 2, 1915, for a "special" over the Santa Fe Railroad leaving Chicago on July 23 at 10:30 p.m. and Kansas City at 11 a.m. on July 24. Numerous stops and short side-trips are provided for to visit points of particular geological interest and especially places best showing the features of desert erosion, the latter subject being one of

the main themes of discussion at the sessions. For a limited number of other members of the American Association for the Advancement of Science who are intending to be present at the San Francisco meetings and who wish to join the special party, ample provision will be made. Those joining the special party may return home individually at any time and over any route. The cheapest way will be for each person to purchase a round-trip railroad ticket at his home town, via the Santa Fe route from Chicago and Kansas City to San Francisco, with returning privileges over any other route he wishes; this includes stop-overs at Los Angeles and San Diego without additional cost. Pullman reservations, Chicago or Kansas City to San Francisco, should be made early by direct communication with Mr. Samuel Larimer, general agent, passenger department, Santa Fe Lines, 315 7th St., Des Moines, Iowa. The geological direction of the special party will be under the supervision of Dr. Charles Keyes, Des Moines, Iowa, to whom communications may be addressed concerning full information and detailed itinerary. The cost of the side-trips, etc., for the five extra days on the way going will be about \$25.00 above regular individual fares, or about \$35.00 if the Painted Desert trip is taken.

THE third annual joint field meet of the United States Bureau of Mines, the American Mine Safety Association and the California Metal Producers' Association will be held at the Panama-Pacific Exposition on September 23 and 24. It is expected that there will be a large attendance of mining men, as the joint meet will either precede or follow the annual meetings of a number of institutions allied to the mining interests, such as the American Institute of Mining Engineers, September 17 and 18; the International Engineering Congress, September 20 to 25; the American Mining Congress, September 20 to 22; the California State Mine Rescue and First Aid Contest, September 22; and the National Safety Conference, under the joint auspices of the National Safety Council and the California Industrial Acci-

dents Commission, September 27 to 30. On September 28, on the athletic field of the Panama-Pacific International Exposition, there will be a mine-rescue demonstration at 10 o'clock; at 2 o'clock in the afternoon there will be a first-aid demonstration; and at 4 o'clock a demonstration of the explosibility of coal dust. On September 24, at 10 o'clock, will be held a first-aid contest for inter-state supremacy; at 2 in the afternoon a rescue contest for inter-state supremacy; at 4 in the afternoon a rock drilling contest, and at 8 o'clock in the evening, there will be an award of prizes and souvenirs at the convention hall.

UNIVERSITY AND EDUCATIONAL NEWS

THE Illinois legislature has passed a bill appropriating \$5,000,000 for the use of the University of Illinois for the biennium beginning July 1, 1916. This amount lacks but little of being the whole of the fund that has accumulated in the state treasury from the one-mill tax voted four years ago for the support of the state university.

By the will of Miss Helen Collamore, of Boston, \$100,000 is bequeathed to Simmons College, \$20,000 to Radcliffe College and \$10,000 primarily to aid women students in post-graduate courses in the Massachusetts Institute of Technology.

THE General Education Board plans to enter the field of educational research by assisting workers of institutions of learning, as well as supporting experiments and inquiries. Further progress is reported in the project for establishing an institute for training public health workers. A model county organization will be perfected in Mississippi, with the cooperation of the state superintendent. Several appropriations are also announced. Two hundred thousand dollars are subscribed to the Vassar College endowment fund, \$125,000 to that of Denison University, Granville, Ohio, and \$100,000 to Pomona College, Claremont, Cal. The sum of \$140,850 is appropriated for the current year's work in developing secondary and rural schools for both white and Negro races. The board has contributed \$21,000 for

continuing the farm demonstration work for children's clubs in Maine and \$10,000 in New Hampshire, undertaken with the agricultural colleges of these states.

PROFESSOR R. J. POOL has been chosen by the board of regents of the University of Nebraska to be acting head of the department of botany, to fill the place made vacant by the death of Professor Charles E. Bessey. J. E. Weaver, for two and one half years connected with the botanical department of Washington State College, and for the past year with the botanical department of the University of Minnesota, has been appointed assistant professor of botany in the department.

DR. JOSEPH PETERSON, the circumstances of whose resignation from the chair of psychology in the University of Utah have been noted in this journal, has been appointed professorial lecturer in the University of Minnesota. Other appointments at Minnesota are: Elmer J. Lund, assistant professor of zoology; Robert C. Ashby, assistant professor of animal husbandry; Jean MacKinnon, assistant professor of nutrition; Lucile Wheeler, assistant professor of foods and cookery; Merritt R. Grose, instructor in chemistry, and John C. West, instructor in physical education.

DR. GEORGE W. CORNER, now on the staff for gynecology of Johns Hopkins University, has been appointed assistant professor of anatomy, and I. C. Hall, formerly of the Cutter laboratories, assistant professor of bacteriology, in the University of California.

At the University of Illinois Robert Stewart, professor of chemistry in the Utah Agricultural College has been appointed associate professor of soil fertility and assistant chief in soil fertility in the Agricultural Experiment Station. Gilbert Gussler, of the University of Ohio, has been appointed associate in animal husbandry in the College of Agriculture. R. D. Carmichael, of the University of Indiana, has been appointed to be assistant professor of mathematics in the university.

LEE R. DICE, Ph.D. (California, '15), has been appointed instructor in zoology at the Kansas State Agricultural College.

PROFESSOR GILBERT GUSLER, of the Ohio State University, has been appointed to a position as associate in the department of animal husbandry of the University of Illinois.

DISCUSSION AND CORRESPONDENCE

COMPLEXITY OF THE ALEXANDRIAN SERIES

UNDER the tacit encouragement of our federal and state geological bureaus the unfortunate practise of continually displacing already well-defined and useful terranall titles by new ones, often of very doubtful utility, with the idea in mind that such continual change in nomenclature is the only essential element in the advancement of knowledge, seems to be notably increasing rather than showing any appreciable signs of wane. Lest the shadow permanently be mistaken for the substance every contemplated case of renaming demands beforehand the closest scrutiny.

It was a similar tendency, a generation ago, that led the various geological surveys to dispense with the services of the paleontologist and to adopt the lithologic unit in stratigraphic classification and in cartographic representation. In new form the remaining mania still refuses to be downed.

A recent concrete case is the proposal of the name Alexandrian for an Early Siluric series in the Mississippi Valley. This instance is no worse than a multitude of others. It is selected at random, chiefly because it illustrates in small compass more points than any other that comes to mind. Moreover, it emphasizes three facts of universal application.

There is first the doubtful expedient of erecting groups so large as that of series by merely throwing together all strata lying between two well-known horizons. Second, there is the pernicious habit of making inconsequential additions to or subtractions from already defined formations and proposing therefor entirely new names, when the old terms easily answer without violation of a single canon of nomenclature. In the third place there is little or no consideration of paleogeographical conditions. Until the last-named factor is recognized in something of its true perspective there can be little real progress in

the solution of the broader problems of local stratigraphy.

Now the Siluric section of northeastern Missouri is quite remarkable because of the fact that it is so meagerly represented, because it is divided medially by a marked plane of unconformity, and because there is an overlapping of a southern earlier Siluric deposition by a northern later one.

In the proposal of the term Edgewood formation to include the Bowling Green limestone, the Noix oölite, a local phase of what was later called the normal Noix limestone as noted by Ulrich, and the lower normal limestone to which recently the name Gyrene limestone was given, the significance of the notable plane of unconformity at the base of the Bowling Green member was completely overlooked. It now transpires that the stratigraphic affinities of this formation are with the northern, or Iowa, section instead of with the southern or southern Missouri sequence; that its time relations are with the Mid Siluric rather than with the Early Siluric sub-period. In consequence of these facts Edgement as a terranall designation becomes at once invalidated.

By slight change in the original significance of the term Noix, as applied to a limestone member, this name assumes a useful and valid rôle. The appellation Cyrene for a limestone becomes wholly unnecessary. If in the north Missouri region the term Alexandrian series is to be retained as a permanent stratigraphic title with a taxonomic rank of series it will have to be restricted in its application to the Siluric strata below the plane of unconformity marking the base of the Bowling Green limestone.

According to the rule of nomenclature laid down by its author the term Alexandrian would have to be abandoned and a new title proposed. There is urgent need of a serial term for the Early Siluric section of the Ozark region. It appears a happier treatment of the problem to retain a name already in use, modifying its delimiting application slightly to meet the exigencies of newly discovered relationships. Only in this way can the interests of stable geologic nomenclature be best sub-

served and a term like Alexandrian series be established as a valid stratigraphic title.

CHARLES KEYES

ALABAMA ARGILLACEA IN MINNESOTA

THE cotton-worm moth, *Alabama argillacea* Hubn., appeared in Minnesota during the past season at several different places. The first recorded appearance was at Garden City, Blue Earth County, September 21, where it was proving injurious to a variety of ever-bearing strawberries. The moths punctured the fruit and apparently did considerable injury.

Between the tenth and the fifteenth of October, several other inquiries from other places were received, complaining of this moth injuring strawberries. One complaint came from Rochester, Minn., one from St. Paul, and one from Excelsior, which is on Lake Minnetonka, west of Minneapolis. The moths apparently stayed but a very short time in each of these places. Between the fifteenth and nineteenth of October the nurseryman at Garden City, Minn., had further trouble from these moths. He sent in a letter that they were most abundant about the twentieth of September, after which they disappeared, becoming rather scarce, but appearing again in numbers about the fifteenth of October.

These few notes may be of interest to entomologists, as they show the northern flight of the moths; also that they will feed on fruit, if fruit is available at that time.

CHEMIDROMETRY

THE writer has been searching for a name for the new method of measuring the flow of rivers, the discharge of turbines and the capacities of reservoirs by means of chemicals mixed with liquids. *Chemidrometry* seems to convey the idea exactly, but it can be criticized in at least two respects. It is a compound whose component parts are derived from two different languages, which is not good form, and the second part is almost exclusively used when it refers to the determination of density or specific gravity.

An appropriate name for this new branch of engineering will soon be in demand and it is, therefore, suggested that other names be submitted by your readers for consideration.

B. F. Groat

EYE SHADES FOR MICROSCOPICAL WORK

TO THE EDITOR OF SCIENCE: The eye shade described in SCIENCE for May 28 is identical in plan though not quite as perfect in construction as one sold for many years by dealers in microscopic supplies. It was designed by Dr. R. H. Ward and is illustrated in earlier editions of Gage, "The Microscope" (e. g., VI. ed., p. 59), and in various catalogues of micro accessories as Ward's Eye Shade. In the later editions of Professor Gage's book it is replaced by another form which in the author's judgment probably meets the needs of the case more satisfactorily.

The discussion which Professor Gage gives in connection with the figure of the eye shade regarding the care of the eyes is worthy the more careful consideration of the laboratory teacher. Such problems receive little, if any, attention in the training of graduate students, and college classes suffer when every new generation of teachers comes to practice on them.

X

SCIENTIFIC BOOKS

The Climatic Factor as illustrated in Arid North America. By ELLSWORTH HUNTINGTON, with contributions by CHARLES SCHUCHERT, ANDREW E. DOUGLASS and CHARLES J. FULLMER. Carnegie Institution of Washington, Publ. 192, 1914. 4to. Pp. 841, richly illustrated.

The senior author of "The Climatic Factor" has for a number of years endeavored to throw light upon the relations between changes in climate and human activity, and the wealth of fact which he personally has hitherto brought to light and correlated with the investigations of others, especially archeologists, in that region called the cradle of western civilization, together with interpretation in terms of climatic oscillation, have won for him much recognition both from a wide circle of the

intellectual laity and within the narrower circle of more critical students. A more fascinating volume to those who endeavor to glimpse the ancients as living beings overcoming and being overcome by their environments, than "Palestine and Its Transformation" has rarely been written, and in it Professor Huntington in a measure has anticipated the feature of the present volume which to the biologist especially will make the most intimate appeal. As the author remarks in his preface, his thesis of climatic pulsations within measurably recent times may till now have been open to the criticism that the facts may have been arranged to fit the theory, but granting this to be so, we have now given us indubitable evidence, mathematically treated, derived from growth rates of the "big trees," so that in the absence of instrumentation we are supplied with a rainfall curve dating back over 3,000 years, which, viewed broadly, is little less dependable for that lack.

The method of attaining this end is credited to Professor A. E. Douglass, who, while resident in Flagstaff, conceived the idea of showing association between meteorological variations and astronomical phenomena during long periods of time for which records are not available. This method is presented by him in Chapter XI. of the volume. The fundamental data are the measurements of the growth rings in old trees obtained in numbers sufficient to allow the determination of the amount of error due to various causes and their elimination. The errors considered by Douglass are those introduced by the irregularities of growth due to discontinuity of moisture supply during the growing season, such errors being of relatively greater importance in comparing growth and recorded rainfall, during a comparatively short period of years. The results of the investigation are correct within a range of 70 to 82 per cent., and certainly sufficiently so to warrant reliance upon tree growth as an indicator of climatic variations. Growth rates for a period of 500 years were then studied, a correction for age being indicated, and from the result it is clearly to be inferred that climatic pulsations have occurred during the period in question. These, it is finally argued,

are expressions of weather changes due to sun-spot activity, a view supported by data from German trees.

In the following chapters Huntington applies the above method, introducing an additional correction for "longevity," the effect of which is to still further rectify the curve embodying a correction for age, and to make the sinuosities of the growth curve comparable at all points throughout its extent. The evidence for pulsations of growth is further found in trees widely scattered from Maine to California. It is, however, to be noted that inverse growth fluctuations occur, as for example when a change which produces a "drought in the north may produce an excess of moisture in the south." This extension of method then leads the way to a dramatic climax in the following two chapters in which the special difficulties presented by the "big trees" of California are dealt with and the interpretation of their growth curves is presented. The original data are recorded in the statistical portion of the volume, where 28 pages are found crowded with tabulated figures at which one must look in order to form some conception of the enormous amount of work of a purely inductive kind upon which the author's conclusions rest. The derived curve of tree growth for 3,000 years and the curve for climatic change in western Asia based upon historical data, on page 172, must remain, whatever the minor inaccuracies may turn out to be, of preponderating interest for students of climate, and will become an item of classical value.

From these curves there emerges the conclusion that beyond the cycles of lesser amplitude embraced within shorter time periods (120, 21 and 11 years) others occur "of the length of centuries" but without recognizable periodicity, and that these pulsations, to use the author's favorite term, have been synchronous in western America and western and central Asia. His methods, tested against each other in this volume, point also to a condition 300 years ago on the whole moister than now obtains.

Inquiry into the possible causes of the discoverable fluctuations occupies Chapter XIX., in which a variety of evidence, including solar

constants, sun-spots, the prices of wheat, size of crops, growth of trees and comparative temperature fluctuations at various points of the earth's surface, contributes to support the conclusion that the "solar hypothesis," meaning the occurrence of sun-spots and a correspondingly cyclic change in the sun's radiation are sufficient to and do account for the causation of measurable meteorological results. The larger question of climatic change during the vast extent of geological time is attacked by Dr. Charles Schuchert in a paleometeorological monograph incorporated into the volume as Part II., in which the crustal deformation of the earth due to gravitational agencies is seen as the cause of change and redistribution of climatic zones. It seems conclusive that periods of mountain-making have been followed by cooler times, though, as Huntington and Schuchert both admit, there still remains the difficulty of accounting for the apparent causal relation between these, for the minor fluctuations of climate which are now in progress, and for the interglacial climates characterized by higher temperatures. At this point the solar hypothesis appears to articulate with that of crustal deformation. A full and impartial discussion of all the theories, in itself quite exemplary, strengthens the authors' positions, but for these details the original volume must be examined.

There remains of the reviewer's task a necessarily brief and equally inadequate mention of the body of evidence from the point of view chiefly of human activity, but including certain topographic facts.

The salient condition for the studies lies in the sensitiveness of the semi-arid desert to apparently minor deviations from the normal course of rainfall, and, for the author's purpose, its effect upon human economy. That these fluctuations of precipitation have occurred, there is abundant evidence in records, and in the fate of modern enterprises; and, according to Huntington, in the making of terraces, new and old, but all embraced within comparatively recent times, which can be seen at the present time well illustrated in the Santa Cruz River at Tucson, in the different levels of lake beds, in the fixation of older and move-

ment of later sand dunes, as illustrated in the White Sands of the Otero basin and in the different ages of ancient aboriginal villages. Evidences of an earlier large population were studied in localities found in the whole wide region from south New Mexico to northern Sonora. The close examination of these evidences is so masterfully done, and with such intimacy of touch, that one feels, as it were, a thread of drama running through it. While the contemplation of history seems to lengthen the years ago, that of the earlier culture of the desert seems, in these studies, to bring us nearer to the past. In particular, the account of the condition on the lower Altar may be cited in illustration of method and treatment. This valley, beginning at the village of Altar and ending at Disemboque on the Gulf of California, contains a string of villages either occupied, as Caborca, with 1,500 inhabitants, and Buzani with a mere handful, but with the ruins of a mission, or uninhabited—and recognizable only from the usual signs—artefacts, foundations, canals, villages extensive enough to accommodate 1,500 folk, perhaps more. Lands now either cultivated opportunistically, but less and less as the gulf is approached or not at all, but always extensive enough for the support of large numbers of the primitive people, together with signs of irrigation works, combine with the ruins, to form a setting for a numerous people. But the people are not there. All the facts point to a condition when agriculture was possible and water was in quantities sufficient to supply the villages by means of canals, in the absence of wells (as at Buzani). A feature of especial interest described is the curious terraces or *trincheras* found at various localities. These merge with rectangular areas, discernible now only from an eminence, on the lower gentler slopes. These *trincheras* were undoubtedly for agricultural use, and this view taken by Huntington, receives support from the occurrence of similar *trincheras* observed by the reviewer in the fastnesses of the Sierra Madre of Oahuahua, associated with the ruins of ancient villages. But if for agriculture, whence the water? A little arithmetic shows pretty conclusively that they could not have been irri-

gated, since the work, which would have been done by the women, would have amounted in the case of the Great Trincheras to enough to demand a population of 15,000, "where now there are scarcely more than 200," in view of which it seems far more likely that dry farming was possible, and this in turn supposes a greater rainfall than occurs at present.

But the main effort is to show that not only has there been a change in rainfall during the last few hundred years, but that the whole region studied presents evidences of successive stages of culture. The evidence derived from human agencies is of course the more difficult to obtain and interpret, but taken together with that from other sources, it gives more than suggestive strength to the discussion. For example, the early Spaniards found no inhabitants in the Chaco Canyon, while their artefacts show them to have been different from the more modern Pajaritans. The extremely dry character of the region indicates that it would have become uninhabitable earlier than other localities which have been occupied at later dates.

In this connection southern Mexico is treated as a test case and similar conclusions are arrived at, while three other chapters deal with Yucatan, with Guatemala and the Highest Native American Civilization, and with the Relation of Climatic Changes to Mayan History. The rich indications, buried now in well-nigh impenetrable jungle, of a highly able and intelligent people, are found in a region which forbids at the present any approach to civilization at all, in view of the great heat, disease and the consequent debilitating effects. But a small decrease in rainfall would alter these conditions, so that what would cause the disappearance of people in temperate regions would permit their greater development in the tropics, since a diminution of rainfall sufficient to allow the development of dense forests would cause them to be replaced by jungle, and the jungle, in turn, by bush. A healthful atmosphere would thus displace a noxious one, and human progress, otherwise inhibited, would be stimulated. But this means that while the deserts of the south-

west are drier now than formerly, the scenes of former Mayan greatness are now moister, in apparent contradiction to the major thesis of the volume. At this point a paper is contributed by Dr. Charles J. Kellmer on "The Shift of the Storm Track." It is shown that during an interval of 21 years the storm track has shifted a small distance to the west and south, and it is perhaps more than a mere coincidence that the magnetic pole has also shifted (according to Bauer) westward and (chiefly) southward. This broaches the subject of the latitudinal change of climate due to this cause, and if, as Huntington contends, such changes have occurred in the lands of the Mayas, the general contention that the profound changes in human culture, indicated by their reliquies, are due to them. In this light, the Mayan history is reviewed in Chapter XVIII., and a parallel is drawn between the climatic changes as registered by tree growth and the rise, decline, renaissance and ultimate reduction to a rather low grade of culture, of the Mayan people, not so low, however, as that of other tropical peoples. In this study, history and archeology are brought together, and if the results are, as Huntington says, not too much to be depended on, the treatment again illustrates the method of coordinating evidence from these and other sources in order to get a broader view of the possible causes of culture changes in the past. The sum total of the work is to strongly indicate a general parallelism between these changes in central America and the desert regions to the north and those of central and southwestern Asia as correlated with the climatic pulsations indicated in the growth records drawn from a minute's study of the California trees.

The volume is a big one, and really too big and too detailed, and with evidence drawn from too many kinds of sources for competent review by a single reader. If this review fails in the critical attitude, a good purpose will be served if, besides indicating the scope of the studies, the general attention is directed to large and conscientious effort, supported by great if restrained enthusiasm, to work out an intricate problem which has an intimate bear-

ing on the history of the human race, that of the relation of culture to climate. Much as has been done, the author would be the last to say that more than a breaking of the ground has been accomplished. He himself is as busily engaged now as before, deriving evidence from all sources available to him, as witness the recent papers on the relation of climate and civilization, work and weather, in *Harper's Magazine*, forecast doubtless of more extensive study of the same kind.

A single matter of book-making should be especially mentioned. In a note to the reader, following the table of contents, a list of segregations of chapters is given for the direction of those more especially interested in one field of thought than another. Such schemes are helpful in these days of much publication.

FRANCIS E. LLOYD

McGILL UNIVERSITY

THE PROCEEDINGS OF THE NATIONAL
ACADEMY OF SCIENCES
(NUMBERS 1-4)

Four numbers of the *Proceedings of the National Academy of Sciences* have now been issued. These contained in 258 pages a total of 70 articles, including the report of the autumn meeting of the Academy. The average length of the contributions was therefore 3.7 pages, which lies well within the limit of 6 pages, or 2,500 words, set by the editors.

The number of articles in the various branches of science is as follows:

Mathematics	11	Astronomy	11
Chemistry	13	Geology	2
Paleontology	1	Botany	4
Zoology	5	Genetics	5
Bacteriology	2	Physiology	8
Anthropology	5	Psychology	2

The inadequate representation of certain sciences, such as physics, geology and pathology, is largely accidental, as many authors in these fields have indicated their intention of contributing to the *Proceedings*.

The arrangement of the articles according to geographical distribution into Eastern, Middle West, and Pacific also shows a reasonable distribution over the whole United States. The figures are:

Eastern ... 35 Middle west ... 21 Pacific ... 13

The Pacific figures show the activities of the great Lick and Mt. Wilson observatories in astronomy; and the Middle West has an exceptional representation in mathematics.

A number of the papers which have appeared in the *Proceedings* were read before the Academy at its autumn meeting and have therefore appeared in abstract in *SCIENCE*. Without making exceptions in the case of these papers, the contents of the first four issues of the *Proceedings* may be outlined as follows:

Astronomy.—An analysis of the radial velocities of nebulae by W. W. Campbell shows that the planetary nebulae are on the average moving much faster than the helium stars, which are supposed to be nearest to the nebular condition; and this leads to the suggestion that these nebulae may have arisen by the collision of fast moving stars with resisting media.

H. D. Curtis, from a study of photographs of nebulae taken at various times throughout a period of thirteen years, concludes that there are upon the plates no evidences of internal motion and little if any of proper motion, indicating great distance and enormous size for these objects.

The announcement of the discovery of the ninth satellite of Jupiter is made by S. B. Nicholson.

R. E. Wilson reports abnormally high radial velocities (some 250 km. per sec.) for nebulae in the Magellanic Clouds, and calls attention to the importance of determining the velocities of stars in the clouds to ascertain whether the clouds as a whole may have such a velocity.

Kapteyn's theory that the universe is mainly composed of two great streams of stars is strongly supported by a statistical study of stellar radial velocities by J. O. Kapteyn and W. S. Adams. New observations of faint stars show that the streams extend to the greatest distances for which data are available.

A. van Maanen's measures of stellar parallaxes with the sixty-inch reflector are apparently of very high precision.

Solar physics is represented by a number of contributions. G. E. Hale and H. D. Babcock seek with the aid of the Stark effect to measure the potential-gradient in the solar atmosphere, and find that at the level in question it does not exceed two hundred times the average value in the earth's atmosphere. A study of the flash spectrum of the uneclipsed sun leads W. S. Adams and E. G. Burwell to infer that the observations without an eclipse represented a lower level than those during eclipse, and that there is a considerable gain in accuracy (owing to the greater linear scale of the Mt. Wilson photographs); the results do not support the hypothesis of anomalous dispersion as explanatory of solar phenomena. C. E. St. John offers an extensive critique of this hypothesis, and concludes that the theory which bases the shifts in the spectral lines on supposed velocities in the solar atmosphere is far more satisfactory than that which explains these shifts by anomalous dispersion.

That spherical aberration may be induced in a thoroughly corrected objective by rapidly changing temperatures is noted by F. Schlesinger, and mechanical devices for removing the inequalities of temperature are described.

C. E. St. John and H. D. Babcock have examined the spectral lines in the iron arc and have discovered that the wave-lengths of many of the lines depend upon the portion of the arc from which the light is taken, a fact which must be recognized in fixing precise standards in spectroscopy.

Chemistry.—Revisions of the atomic weights of cadmium, lead and praseodymium are reported by G. P. Baxter and various collaborators. The values obtained are: cadmium, 112.417; lead, 207.20; praseodymium, 140.92; $\text{Cl}=35.457$ and $\text{Ag}=107.880$ being assumed in the computations. There appeared to be no difference between specimens of lead from different geographical sources.

W. A. Jacobs and M. Heidelberger offer a proof of Dimroth's monomolecular formulas for *p*-aminophenylmercuric compounds as against Pesci's more complicated formulas.

P. A. Løvene and F. B. La Forge state that the 2-aminoheptose isolated by them and named

chondrosamine has the configuration of either 2-altrosamine or of 2-allosamine.

In a series of papers on potassium ammonio argentate, barate, calcate, and sodate, on metallic salts of ammonio acids, and on ammonobasic iodides of aluminium, E. C. Franklin reports further progress on his extensive investigation on the analogies between aqueous and liquid-ammonia solutions.

The use of J. J. Thomson's electron theory of valence and of various modifications of that theory is discussed by J. Stieglitz, both descriptively and (with collaborators) experimentally, in papers on the molecular rearrangements of triphenylmethane derivatives with the conclusion that the original Thomson theory is extremely useful, but that its newer modifications are not necessary so far as the present investigation is concerned.

An extended investigation of the effects of lipases in hydrolyzing esters is described by K. G. Falk. He comes to the conclusion that the specific character of these effects is due in some cases to the influence of the ester on the enzyme in causing its coagulation or precipitation, and in other cases to the influence of the enzyme on the ester arising from the presence in the former of special groupings similar to those in amino-acids and peptides, which also bring about hydrolysis of esters, as shown by the experiments of the author made in collaboration with M. L. Hamlin.

E. W. Washburn and J. W. Read show that the freezing-points and the eutectic point of solutions, however concentrated, of two substances which conform to the laws of ideal solutions can be calculated; and they communicate experiments which show close concordance of the observed eutectic points with those calculated. They derive from their considerations the following quantitative principle relating to solubility: When a crystalline substance *A* is dissolved in any solvent *B* with which it forms an ideal solution, its solubility is independent of the nature of the solvent *B*, and depends merely on the temperature and on the melting-point and heat of fusion of the crystals *A*.

E. W. Washburn and E. B. Millard show that the electrolysis of a solution of cesium

chloride containing raffinose at low concentration is attended by a decrease in the anode-portion, and an increase in the cathode-portion, of the ratio of the quantity of water to that of raffinose. This result proves that there is a net transfer of water to the cathode, and therefore that the cesium ion is hydrated to a greater extent than the chloride ion. The cesium ion is shown to be the least hydrated of the ions of all the alkali elements previously studied.

Geology.—A voyage through the Pacific to visit coral reefs for the purpose of discriminating between various theories proposed to account for their formation convinced W. M. Davis that Darwin's original theory of subsidence gives by far the most satisfactory explanation of all the barrier reefs he visited.

G. F. Becker proposes to consider the earth as a heat engine competent to bring about all the dynamical effects with which geology has to deal by the stress and strains which would arise during cooling, due to local differences of the tendency of the surface layer to lose heat.

Paleontology.—The hypothesis advanced by C. D. Walcott that bacteria probably were an important factor in the deposition of the Algonkian limestones has received strong support by his discovery of bacteria resembling Micrococci in the fossil alga of the Newland limestone.

Botany.—C. J. Chamberlain presents a phylogenetic study of Cycads based upon detailed field-work extending over a decade.

Phoradendron is classified by W. Trelease into two primary groups: Boreales containing 60 and *Aequatoriales* containing 202 differentiable forms, most of which he regards as species.

From a study of the morphology and relationships of *Podomitrium malaccense* D. H. Campbell decided that *Podomitrium* is much more like *Blyttia* than like *Metzgeria* and should be placed in the Blyttiaceae rather than Aneuraceae.

That the loss of viability in seeds with storage is a matter of coagulation of cell proteins, and that there is a possibility of determining a quantitative statement of the significance of various storage conditions, is indicated by a

study of the germination of wheat by W. Crocker and J. F. Groves.

Zoology.—Experiments on the fertilizing power of sperm dilutions of *Arbacia* indicate to F. R. Lillie that the loss of fertilizing power is due not to loss of motility of the spermatozoa, but to loss of their activating substance, which he designates as sperm receptors; light is also thereby thrown on the process of fertilization.

C. Zeleny and E. C. Faust investigate dimorphism in size of spermatozoa with its relation to the chromosomes, and come to the conclusion that such dimorphism must exist very generally and is probably the result of chromosomal dimorphism present in the spermatozoa.

R. Goldschmidt reports experiments which point to the probability that the general processes of spermatogenesis are necessary reactions of the cells to a systematic regulation of the osmotic conditions on the part of the follicular membrane; the individual specific processes are caused by the specific properties of the reacting cells.

Extensive experiments on flounders show that their remarkable ability to simulate the color and pattern of the background against which they rest is controlled by their visual perception of the background and that the rapidity of the adaptation to surroundings is greatly increased by frequent practice, according to S. O. Mast.

A quantitative ecological study of the Madreporian corals of the fringing reef of Maer Island is presented by A. G. Mayer; the destructive effects of temperature, silt, etc., are discussed.

Genetics.—C. B. Davenport has two articles upon the feebly inhibited: I. Violent temper and its inheritance; II. Nomadism or the wandering impulse with special reference to heredity. The nomadic instinct is fundamental in man, but is inhibited in well-regulated individuals. The tendency to outbursts of temper is probably a dominant trait.

By studying quantitatively the color patterns of a race of rabbits bred especially for the purpose W. E. Castle and P. B. Hadley obtain what they regard as conclusive evidence

against the idea of unit-character constancy or "gametic purity."

Experiments on self-sterility incline E. M. East away from simple Mendelian formulas of the type suggested by Correns and toward Jost's idea of "Individual stoffe" and a near-Mendelian interpretation.

In an attempt to analyze the normal variation of an organism from the standpoint of *Entwicklungsmechanik*, R. Pearl and F. M. Surface study growth and variation in maize. They find that the differences in the manner of growth of individual plants and of groups of plants can not be explained as the effect of environmental factors, but should be regarded as due to internal factors; they regard the differences as due to independent Mendelian factors distributed at random in any population of open fertilized maize plants.

Bacteriology.—W. A. Jacobs and M. Heidelberger report upon a new group of bactericidal substances obtained from hexamethylene-tetramine.

In experiments upon *B. coli*, E. O. Jordan finds an instance of bacterial mutation which seems to fulfil the requirements of appearing suddenly without intermediate stages, of being irreversible, of comprising change of two characters, and of not involving all of the cells of the parent strain.

Physiology.—In a series of short notes F. G. Benedict (with collaborators) sets forth these results: The gaseous metabolic processes of vegetarians are qualitatively and quantitatively essentially those of non-vegetarians of similar height and weight. There is a distinct tendency for athletes to have a measurably larger basal resting metabolism than non-athletes. Men disclose a basal metabolism some 5 or 6 per cent. greater than women of similar height and weight. The general conclusion is that the basal metabolism of an individual is a function, first, of the total mass of active protoplasmic tissue, and second, of the stimulus to cellular activity, existing at the time the measurements are made. The 416-page monograph containing chemical and physiological studies of a man fasting thirty-one days, recently published by the Carnegie Institution, is represented in the *Proceedings*

by a chart indicating the trend of the most important factors measured.

An exposition of a dynamic conception of the organic individual is given by C. M. Child in terms of metabolic gradients. The region of high metabolic rate determining the gradient arises from the differential action of factors external to the organism and becomes the chief determinant of the rate in near-by regions, thus finally dominating the whole individual and affording a basis for the orderly development of the whole which is observed throughout nature.

According to S. Tashiro the nerve impulse is a propagation of chemical change, a propagation due to restoration of an equilibrium disturbed by the increase of metabolism at the point of stimulus and proceeding toward the point where there is less chemical activity as measured by production of carbon dioxide.

J. Loeb and H. Wasteneys find that heliotropism in animals and plants is essentially the same.

Anthropology.—Caribou and related types of culture among the Indians and the diffusion of horse culture among them are treated in two articles by C. Wissler.

A. C. Fletcher reports upon her studies of Indian music.

An examination of Barbados convinces J. W. Fewkes that Barbados had in prehistoric times a large local population whose culture resembled that on the other West Indies.

A. Hrdlicka gives an account of the anthropological expeditions sent out to collect material for the exposition at San Diego.

Psychology.—An outline of a point scale for measuring mental ability, a revision of the Binet scale, is given by R. M. Yerkes. The same author sketches the results of his experiments upon color vision in the ring dove.

Mathematics.—L. E. Dickson offers two papers upon his new modular geometry. Two notes on abstract groups are due to G. A. Miller. Point sets and allied Cremona groups are treated by A. B. Coble, and H. S. White gives an account of his investigation of triad systems. The theory of surface is discussed by E. J. Wilczynski and L. P. Eisenhart, and F. L. Hitchcock submits a classification

of quadratic vector functions. Analysis is represented by a contribution from G. A. Bliss on functions of lines and one from A. Dresden upon the calculus of variations.

A MODIFICATION OF THE BELLANI POROUS CUP ATMOMETER

A RECENTLY renewed and increased interest in the direct measurement of the evaporating power of the air¹ has brought the atmometer (incorrectly called evaporimeter, etc.) into greater prominence than has heretofore been enjoyed by that instrument. Atmometers are now being used more than ever before, especially in plant physiology, plant and animal ecology, and the agricultural aspect of climatology.² This newer development of atmometry

¹The evaporating power of the air may be thought of as the reciprocal of the resistance offered by the air to evaporation from exposed liquid water. The term is a misnomer to a degree, for evaporation proceeds from a water surface in spite of the conditions obtaining in the surrounding air. *Ceteris paribus*, the greater is the air pressure, the less rapid is evaporation; the less water is contained in the air the more rapid is evaporation, etc. The term has come into rather general use, however, and may as well stand till a better is suggested; it is logically no worse than the word suction, and, like it, is readily understood by everybody. *Condensing* power or *water supplying* power can not here be used in place of *resistance*, because air without water-vapor offers resistance to evaporation but has no condensing power; it can not deposit water upon a surface, no matter what its pressure may be. The resistance offered by much dry air can be expressed in terms of an equivalent condensing power, however.

Chicago Bull. 5, 1913, pages 162-65. Livingston, B. E., and L. A. Hawkins, "The Water Relation between Plant and Soil," Carnegie Inst. Wash. Pub. 204, 1915 (the first paper of that publication). Shive, J. W., "An Improved Non-absorbing Porous Cup Atmometer," *Plant World*, 18: 7-10, 1915. Livingston, B. E., "Atmometry

has emphasized the employment of water-impregnated solids to furnish the evaporating surface from which the rate of evaporation is studied, and has discouraged the use, for many purposes at least, of the open pan or tank of water so commonly met with in meteorological and general climatological literature. It has thus come about that considerable misunderstanding has arisen as to what atmometry is really aiming at and as to the relative desirability of studying evaporation from one or another kind of evaporating surface.

Of all the different forms of water-impregnated surfaces employed in the study of atmospheric evaporating power, the cylindrical porous clay cup of Babinet³ has met with the most favor among biological and agricultural workers, and the standardized porous cups now in general use follow the principle of Babinet's device. This type of atmometer possesses a number of pronounced advantages over the free water surface, when atmospheric evaporating power is to be studied as an environmental condition affecting animals and plants. Among these advantages may be mentioned the fact that the evaporating surface of the cup projects up into the air like most animal and plant surfaces. Thus it does not so readily become clogged, as it were, by its own vapor blanket, as does a horizontal surface. Furthermore, the porous cup instrument is much more readily and precisely read than is the open tank, and very short time intervals may consequently be employed. I have frequently constructed graphs showing the march of evaporating power by minute or 5-minute rates, a procedure hardly possible with any form of pan atmometer. More important than any other of the advantages here in question, however, is the one depending upon comparative variability of the evaporating surface with and the Porous Cup Atmometer," *Plant World*, 18: 21-30, 51-74, 95-111, 143-149, 1915. reference to wind action. When ripples or waves are formed on a free water surface the surface is very markedly altered, and this kind of alteration occurs so generally and so uncontrollably with pan or tank atmometers exposed in the open, that it renders futile any detailed study of evaporating power carried out with such instruments. Properly cared for and properly operated, the porous cup surface does not appreciably alter, at any rate it is never altered by wind action. Other advantages of the porous cup over the free water surface are related to errors in reading the latter type of atmometer arising from splashing and spray, the removal of water by animals and the capture of animals, wind-blown leaves, etc., in the tank; none of these errors are encountered in the operation of the Babinet atmometer. Also, the porous cup may be so mounted as not to absorb rain, which always plays havoc with readings from open pans.

For certain purposes, however, such as the study of atmospheric evaporating power at or near the soil surface or the surfaces of reservoirs, etc., the porous cylinder is not well suited; here a plane evaporating surface is frequently requisite. The well-known Piche atmometer, or Cantoni's* or Houdaille's* modification of the latter, all three employing blotting-paper disks, may be used in such cases, but these instruments are less convenient in operation than is the porous cup, in various ways. It therefore seemed desirable to bring into use what amounts to a porous clay cup with a plane evaporating surface. Just such an instrument was devised and described

very long ago by Bellani,[†] who appears to deserve credit for first employing a water-impregnated solid connected by a simple water column with a reservoir at a lower level. The principle here involved forms the basis of the Piche-Cantoni and Babinet instruments as afterwards constructed.

It is hard to understand why Bellani's device should have remained unmentioned during nearly a century of climatological and meteorological advance. Especially surprising is this lack of recognition when it is appreciated that this horizontal plate of Bellani is exactly the form of instrument that should have replaced the open pan in the vain struggles of meteorological students to obtain the long-sought "evaporation formula"; thus might have been avoided, perhaps, some of the wasted effort expended in attempts to express by a single term the influence of wind upon evaporation, when the latter was measured from the variously rippled surface of free water.

In Bellani's atmometer, a horizontal porous clay disk closed the top of a vessel completely filled with distilled water, so that the lower surface of the disk was in contact with the liquid, while the upper surface was exposed to the air. A horizontal, graduated glass tube, of small bore, open at its distal end, projected laterally from the vessel, and the air-water meniscus in the tube progressed toward the vessel as evaporation occurred, the tube thus becoming more or less rapidly emptied of water. A suitable reservoir and cock allowed the meniscus to be pushed back over the scale, by admitting more water into the vessel. As water evaporates from the porous surface of such an instrument more is imbibed from below, and air pressure drives the meniscus inward along the scale, keeping the vessel completely filled and the plate continuously in contact with the water below. The instrument may be mounted with a burette reservoir, as is frequent with the porous cups now in use, instead of the horizontal graduated tube.

After some preliminary discouragement I have at length been able to obtain circular

porous clay plates (77 mm.—3 in.—in diameter) mounted across the large end of a glazed porcelain funnel. The apparatus is made as a single piece, the funnel wall and the disk being continuous, and the lateral surface is afterwards heavily glazed externally. The funnel part is nearly hemispherical, with the cylindrical neck projecting outward from the spherical surface, opposite the center of the porous disk which closes the hemisphere at the top. A vertical section of such a piece is shown in Fig. 1. In operation, the opening

FIG. 1.

is closed by a rubber stopper bearing a tube reaching to the water reservoir below, just as in the case of the ordinary porous cup atmometer. Of course it is not at all essential that the plate be horizontal; it may be exposed in any direction, even downward. All that is necessary is that the water level in the reservoir be at a lower level. It may be mounted on a bottle or a burette, or any convenient form of reservoir, and the non-absorbing mounting may be employed to prevent the absorption of rain. In general, these Bellani plates are to be operated just as are the ordinary porous cups. Where a plane evaporating surface is required, they possess all the advantages of the free water surface and none of its disadvantages. They also possess all the general advantages of the porous cup instrument.

BURTON E. LIVINGSTON

THE EFFECT OF TEMPERATURE ON THE LIFE CYCLE OF *MUSCA DOMESTICA* AND *CULEX PIPIENS*

OWING to a scarcity of data necessary to illustrate the relation of the temperature to the rate of breeding of flies and mosquitoes, a set of experiments was undertaken at the sug-

gestion of Professor C.-E. A. Winslow, to determine (approximately) this relation.

These experiments were made possible through the courtesy of the department of natural history of the College of the City of New York in loaning us three incubators for the purpose.

The experiments began late in July, 1914, and ran through to the middle of September.

An effort was made to eliminate all factors but that of temperature.

Individual variations among different batches of eggs were eliminated by dividing the same batch into three portions to be incubated at the three temperatures.

Larvæ reared from the batches of eggs compared were fed on the same food.

The light, throughout, was either diffused or absent, and the same condition obtained in the batches compared with each other.

By exposing several tumblers of water in each incubator, the atmosphere was kept in a high state of saturation.

All vials containing the breeding fly larvæ were of the same cross section and the height of manure was about the same in each, *i. e.*, from 1½ to 2 inches; the mosquito-larvæ vials and infusions were also uniform.

From the above it will be seen, that although the results may not indicate a breeding rate generally true for each temperature, they nevertheless offer a fair comparative study of the rate at the three temperatures.

Experiments with Flies

Experiments with the life cycle of flies will be treated first.

Egg batches were obtained in the following way: Flies were caught by net and females with gorged abdomens selected. These were first placed together in large fruit jars containing rotten fruit (plums), and the jar was

observed from time to time for deposits. This method proved too cumbersome, and another method was later employed, that of isolating two or three gorged females in a 2-oz. vial over a portion of egg-free manure. Manure from the same dropping was used for all vials in each series.

As egg batches were deposited their removal followed as soon as they were observed.

Each batch was divided into three parts, and the eggs placed in vials on about an inch and a half of egg-free manure and incubated at 20°, 30° and 35° C., respectively.

The manure was examined twice daily, morning and afternoon, by carefully stirring up the manure, and any changes were recorded. Records were made under the following heads: Date of incubation; date of appearance of larvæ; date of appearance of pupæ; date of appearance of adult.

The first series of experiments was greatly hampered by fluctuation in temperatures of the incubators and by the appearance of molds in the fly cultures which in almost all cases prevented the completion of the life cycle. These first experiments are omitted and only those broods that came through without mishap or nearly so are recorded.

The accompanying table gives the average periods for each stage at the three temperatures. (Complete data are appended.)

EXPERIMENTS WITH MOSQUITOES

Batches of eggs were collected every morning from a rain barrel and each batch was divided into three portions, and each portion placed in a 2-oz. vial on the surface of a manure infusion. The manure infusion was selected from a series of tested media since it proved a most satisfactory medium for the larvæ and pupæ. About 1½ grams of manure were added to 40 c.c. of tap water. The vials were incubated at 20° C., room temperature, and 30°, respectively; 35° proved fatal to these insects in most cases. The vials at room temperature were kept out of air currents by placing them in a box. This precaution, however, did not prevent an evening drop in temperature of 5 to 8 degrees, but on the whole the room tempera-

ture was between the two incubator temperatures.

The following table gives the average length of period of each stage:

TABLE II
Average Duration of Each Stage—Mosquitoes

Temp.	Egg Stage	Larva Stage	Pupa Stage	Total

DISCUSSION

A study of Tables I. and II. brings to mind the interesting results of Snyder on the rate of heart beat of the tortoise heart. He found that between temperatures 5° and 30° C., the number of heart beats is doubled to trebled for every rise of 10° C. temperature.

SNYDER'S RESULTS ON THE RELATION OF TEMPERATURE TO THE RATE OF HEART BEAT

Time. Minutes	T=10°		T=20°		T=30°	
	Heart 1	Heart 2	Heart 3	Heart 4	Heart 5	Heart 6
5	9.5	9.5	21.5	21	48	48
10	7	9	21	24	48	44
15	6.7	8.7	19	18	48	40
20	7	8.2	19	16.5	41	
30	7	7	16	14		
40	6.5	7.9	15.5	15.5		
50	6.5	7.9	13.5	16		
60	6.2	7.4	13	15		
80	6.2	6.8	11	14.5		
100	6.5	7.1	10	10		
120	6.4	6.6	8	10		
140	6.5	6	8	9		
160	6.5	5.9	7.6	9		

These results agree with the work of Clausen (reference 2, below) on the amount of CO₂ produced by 100 gr. seeds of lupines in one hour at different temperatures.

CLAUSEN'S RESULTS ON THE RELATION OF TEMPERATURE TO THE AMOUNT OF CO₂ PRODUCED

Temperature	CO ₂ Produced
0°	7.27
5°	13.88
10°	18.11
15°	34.37
20°	43.55
25°	58.76
30°	85.00
35°	100.00
40°	115.90
45°	104.45
50°	46.20
55°	17.70

Both the above tables as well as my own show a general agreement with the chemical-physical law of van't Hoff and Arrhenius (reference 2, below) which states that the velocity of chemical reactions is raised to between two and three times its original amount, whenever the temperature advances 10° C.

The more recent work of E. D. Sanderson and L. M. Peairs indicates this same relation of temperature to insect life.

S. D. KRAMER

AMERICAN MUSEUM OF NATURAL HISTORY

SOCIETIES AND ACADEMIES

THE BIOLOGICAL SOCIETY OF WASHINGTON

The 540th meeting of the society was held in the Assembly Hall of the Cosmos Club, Saturday, April 17, 1915, called to order by Vice-president Rose at 8 P.M., with 50 persons present.

Under the heading Brief Notes, Dr. L. O. Howard called attention to the development of mosquito larvae and adults in pools of water formed by melting snow in the mountains of New York state, the eggs having been laid on the ground the previous summer in places where pools would be formed.

The first paper of the regular program was by J. D. Hood, "Some Features in the Morphology of the Insect Order Thysanoptera." Mr. Hood gave a general account of the Thysanoptera, called attention to the large amount of systematic work that had been done in it during recent years, and said that it was estimated that about 25,000 forms would be found to exist in the order. He called particular attention to the structure and mechanics of the foot, and to the asymmetrical mouth parts, illustrating the peculiarities of each by diagrams. Mr. Hood's paper was discussed by Dr. Howard.

The second paper of the regular program was by Mr. E. A. Goldman, "Biological Explorations in Eastern Panama." Mr. Goldman gave an account of his work in connection with the Smithsonian Biological Survey of the Panama Canal Zone, in 1912, in extreme eastern Panama, with a view to determining the faunal relations of that section to the Canal Zone and to western Panama. Very little zoological collecting had previously been done in the region which was scarcely better known than in the sixteenth century, at the time of the Conquest.

The region proved to be mainly southern American in faunal characters, with a slight admixture of north and middle American elements. Many South American species apparently reach their northern limits here. The collections of birds and mammals have been identified, and about forty of the mammals and thirty of the birds have been described as new. Among the birds are three new genera, two of them of humming birds. No new genera of mammals were taken, but several had not previously been reported from Panama. A new species of *Capybara* was among the more notable mammals. Spiny rats of the genus *Proechimys* were found common. The tail, normally long in this animal, is lost through some pathological condition in many individuals, and owing to this circumstance the natives believe in the existence of two species.

Mr. Goldman's paper was illustrated by lantern slide views of the country explored, and of objects pertaining to its natural history. It was discussed by Messrs. Wetmore and Lyon.

The third and last paper of the program was by Vernon Bailey, "Notes on Variation Distribution and Habits of the Pocket-Gophers of the Genus *Thomomys*." Mr. Bailey said these rodents constituting a genus of the peculiar American family Geomyidae are distributed over the western United States extending from Alberta and British Columbia to southern Mexico. They range from the Arctic Alpine to the Tropical zonal areas and are generally abundant in the regions they inhabit. They are burrowers, live almost entirely underground and are probably more restricted in their individual habitats than any other of our native mammals. This to some extent accounts for their great range of variation and the large number of recognizable forms, nearly ninety. Almost every change in climate, soil and environment is reflected by some change in the color, size, proportions, or cranial characters. There is wonderful adaptation in their color to that of the soil inhabited by them, varying from creamy white on the light sands of the lower Colorado River flats to dark browns on the volcanic plateaus of Mexico and Arizona, and almost black along the humid Pacific coast region of northwestern California. There is also a pure black form on the coast of Oregon which may be an extreme case of dichromatism, as there are several species with a well-marked black phase.

Their habit of burrowing enables the gophers to escape many enemies and to adapt themselves to rigorous climatic conditions. In the past this

habit was useful in keeping the soil upturned and "ploughed," but under artificial cultivation by man this habit renders the animals a pest. They are very destructive to root crops, clover, alfalfa and grain. By cutting roots they often do much damage to orchards, nurseries and vineyards. They may be destroyed by trapping or on a large scale by placing poisoned food in their burrows. In a revision of the genus just submitted for publication as a number of the *North American Fauna* a general discussion of the habits is given as well as descriptions of species and subspecies, and maps showing distribution.

Mr. Bailey's communication was illustrated by lantern slides from photographs of living animals and of their work.

Messrs. Cooke, Wilcox, Howard and others took part in the discussion.

THE 541st meeting of the society was held in the Assembly Hall of the Cosmos Club, Saturday, May 1, 1915, called to order by Vice-president Rose at 8 P.M., with twenty-six persons present.

On recommendation of the council, Admiral G. W. Baird was elected to active membership.

Under the heading of Brief Notes and Exhibition of Specimens, Dr. O. P. Hay made remarks on the extinct ground sloths of America and called attention to the existence of a specimen of *Nothrotherium* from the North American Pleistocene, in Baylor University, Texas. Mr. Wm. Palmer announced that he had lately seen an apparently wild specimen of the European skylark in near-by Virginia. He also exhibited the jaws of a ray, *Rhinoptera bonasus*, collected at Cheapeake Beach, Maryland. Mr. E. W. Nelson called attention to the newspaper notoriety attained by the San Antonio (Texas) bat roost erected under the misconception that bats were destructive to mosquitoes. He said there was no evidence that the species of bats (*Nyctinomus mexicanus*) in these roosts consumed mosquitoes, and that they foraged so far from these roosts that there would be little likelihood of their consuming insects in the vicinity of San Antonio.

The first communication of the regular program was by C. W. Gilmore, "Observations on New Dinosaurian Reptiles."

The speaker discussed briefly some of the more important discoveries of dinosaurian fossils made in North America during the past two or three years, referring especially to the explorations conducted by the American Museum of Natural History and Canadian Geological Survey in the Ed-

monton and Belly River formations in the Province of Alberta, Canada. He stated that the recent finding of several specimens with which was preserved impressions of considerable parts of the epidermal covering, leads us to hope that the time is not far distant when the external appearance of these animals will be as well known as is the internal skeleton.

Lantern slides of many of the more striking specimens were shown, the speaker confining himself to brief explanatory remarks regarding their systematic position and their more striking characteristics. The following forms were discussed, *Saurolophus* and *Corithosaurus* of the Trachodont dinosaurs; *Ankylosaurus*, an armored reptile; *Monoclonius*, *Anchiceratops*, *Ceratops*, *Styracosaurus* and *Brachyceratops*, all of the Ceratopsia or horned dinosaurs. In conclusion, life restorations of *Brachyceratops*, *Thecelosaurus* and *Stegosaurus* modeled by the speaker were exhibited for the first time.

Mr. Gilmore's communication was discussed by Messrs. O. P. Hay, Nelson and Lyon.

The second communication was by William Palmer, "The Basic Factors of Bird Coloration."

The complex and varied coloration of birds was explained as due to several causes, which were grouped as pigmental, structural, chemical and a mixture of two of these. The basic pigmentation was considered as composed of blackish, reddish and yellowish cells, the latter being much subdued and principally diluting the others. This coloration group was classed as physiological, in contradistinction to all other tints, colors and glossiness, which were considered as psychological results due to semi-consciousness, especially to eyesight, food and certain phases of light.

This arrangement was based on the experience of the speaker on the forest slopes of Mt. Gede, in western Java, where it was found that non-glossy, dark and dingy colored birds were confined almost entirely to a habitat of damp, dense ground-cover vegetation, while those clothed in more or less brilliant colors were inhabitants of the intermediate areas above the ground cover and below the dense canopy of the branches of the tall forest growth.

In the tops of the forest trees a different type of coloration was evident; glossy blacks, whites and grays, were exclusively characteristic, or predominant. These types of coloration were continued down into the lowlands in the same order, but with different species or genera, and with the tree-top type spreading through the more open

and drier areas of the lowlands to near and on the ground.

Less definite intermediate areas between the ground cover and the tree tops, less dense, or with a different vegetation, were shown to be habitats of birds largely green or yellow, the result being that given the general and special coloration of a bird its habitat could be largely or clearly indicated, apparent exceptions having been greatly influenced by other factors.

A correlation was made of these distributional results with the birds of eastern North America, which were considered as governed by the same influences, though forest changes have in modern times greatly complicated the question.

The coloration of other animals is governed by the same laws with similar results, so that where white, glossy black, bright and highly colored areas exist on animals, it is due to psychological progressive adaptations, based on a less complex and simpler dull coloration to be considered as basic, primitive, and thus more purely physiological in contrast.

Mr. Palmer's communication was discussed by Mr. Nelson and Hon. George Shiras, 3d.

M. W. LYON, JR.,
Recording Secretary

THE BOTANICAL SOCIETY OF WASHINGTON

THE one hundred and fourth regular meeting of the Botanical Society of Washington was held in the Assembly Hall of the Cosmos Club at 8 P.M., on Tuesday, April 6, 1915. Forty-five members and fifty-three guests were present. Mr. W. R. Chapline, Jr., was elected to membership. The following scientific program was presented:

Prepalaeozoic Algal Deposits: CHARLES D. WALCOTT.

Mr. Walcott described the stratigraphic position of the great Prepalaeozoic Beltian series of central Montana, which he considered to be of fresh or brackish water origin. They were deposited in a large inland lake or lakes covering approximately 8,000 square miles of area, also on river flood plains as sand and gravel, or as fine dust carried by the wind. The formations now consist of sandstone, siliceous shales, calcareous shales and beds of limestone, the last varying in thickness from a few inches to several thousand feet. The same type of deposits also occurs in the Grand Canyon region of Arizona, and they extend northward along the main ranges of the

Rocky Mountains far into Alberta and British Columbia.

At a horizon approximately 9,000 feet below the base of the Cambrian numerous reefs of algal deposits occur at several horizons in the Newland limestone formation of the Beltian in Montana, and isolated concretionary-like forms occur scattered at various levels in the overlying Spokane shales of the Belt Mountains. The algal remains occur in many forms, some of which are surprisingly similar to those of the fresh-water lake and stream, blue-green algal, deposits of Pennsylvania, New York, Michigan, etc. Others are similar in appearance to the blue-green and green algal deposits of the thermal waters of the Yellowstone National Park.

Mr. Walcott illustrated by lantern slides the various forms of algal deposits as they occur in the Pre-Cambrian rocks and also recent deposits. Photographs of thin sections of both the fossil and recent deposits showed similar chains of cells which are characteristic of the blue-green alga. Other photographs illustrated recent bacteria and those associated with the algal remains in the Prepalaeozoic of Montana. These included the Micrococci, with both round and oval cells. Some of the sections appear to carry rodlike bacilli.

The Algal Flora of Some Eocene Oil Shales:

CHARLES A. DAVIS.

Extensive beds of petroleum-yielding shales of Eocene age occur in northwestern Colorado and westward. They are carbonaceous, and when fresh are dark brown, hard, tough and compact, with a bituminous odor. So far as observed, they contain no free oil, but yield petroleum on distillation.

By modifying methods of sectioning employed by various investigators in studying coals, the author successfully sectioned these shales by microtome. The sections show an organic detrital magma containing an extensive microscopic flora, which includes a large number of perfectly preserved micro-algae related to blue-green and higher types.

Thirty-five lantern slides showed the various algae found in these shales.

Algae in the Upper Palaeozoic: DAVID WHITE.

Corresponding Secretary

ANTHROPOLOGICAL SOCIETY OF WASHINGTON

At the 484th meeting of the society, held March 2, Mr. E. T. Williams, of the Department

of State, read a paper on "Confucianism." It existed before Confucius was born but was called by his name because its sacred books were in large part edited by him and he is now one of the chief objects of worship in the system. Confucianism is not merely a system of ethics, as an elaborate description of its rites and sacrifices showed. In 1907 the Empress Dowager raised Confucius to equal rank with the Supreme Deity in the pantheon. President Yuan Shih-kai participated last September in the worship of Confucius at the temple in Peking and offered sacrifice to Shangti in the Temple of Heaven. Ancestor worship prescribed by Confucianism is kept up in private life but Buddhism also is popular in its modified form, which offers immortality in the "Western Heaven." Freedom of worship is claimed in China.

DANIEL FOLKMAR,
Secretary

THE NEW ORLEANS ACADEMY OF SCIENCES

THE regular monthly meeting of the academy was held on Tuesday, April 19, at Tulane University. The president, Dr. Gustav Mann, in the chair and thirty-two members and fellows present. The first paper of the evening was read by Professor Hugh Mercer Blain, of Louisiana State University, "The Old South in Humorous Sketch and Story." Following Professor Blain's paper were two short papers, the first by Dr. J. H. Clo, "A New Form of Conductivity Bridge." A description of a direct-reading device for measuring the electrical conductivity of conductors between the limits 10^{-6} and 10^{-8} with a modification by which the instrument may become an ohmmeter of wide range. The second was by Dr. F. P. Chillingworth, "Some Notes on the Mechanism of the Heart," illustrated by an original model devised by the speaker. All three papers were the subject of discussion.

R. S. COCKS,
Secretary

THE AMERICAN PHILOSOPHICAL SOCIETY

At the meeting of the society held on May 7, the following paper was read:
Oil Concentration of Ores: HOWARD W. DuBOIS.

Oil has recently been found to be very efficient in the concentration of ores of the base metals, especially copper and zinc. Many of the largest mining companies are adopting this process where water concentration methods have given an unsatisfactory recovery due to the metals having a specific gravity similar to the gangue.

The exact action of the oil is rather imperfectly understood, as the exceedingly small quantities (less than $\frac{1}{10}$ of one per cent. in some cases) employed have a concentrating action quite disproportionate to the quantities of oil used. In brief, the concentration seems to be due to the selective action developed by the oil, which coats the metallic particles with a thin film forming an attractive medium for the attachment of gas bubbles produced in the process. These bubbles act like so many life preservers, causing the metallic particles to float on the surface and are collected continuously. The gangue is precipitated through the mass of the oil-water mixture and is drawn off continuously. Some ores which would only give a 50-per-cent. extraction by the standard water concentration methods have given a recovery as high as 93 per cent., by the oil process.

The process is a very cheap one and can be applied to a great variety of ores. The courts have declared that the process is open for use without royalty obligations. The installations already made indicate that it will revolutionize concentrating methods for the base metals and will play the same part in cheapening the extraction of the base metals as the cyanide process has in the case of the precious metals.

THE INDIANA ACADEMY OF SCIENCES

THE Indiana Academy of Sciences met at Bloomington, Ind., on Thursday, Friday and Saturday, May 20, 21 and 22. On Friday evening Professor Foley, of the physics department of Indiana University, gave a lecture on "Electrical Discharges," which was illustrated by about fifty experiments. A "smoker" followed the lecture. On Friday morning fifty members tramped to the reservoir belonging to the university, making a study of the geology and botany of the region en route, and at noon a picnic luncheon was served by the local members. On Friday afternoon automobiles were provided and the party visited a number of the limestone quarries and stone mills of the district. Many interesting operations were witnessed, among them the diamond sawing and the turning of limestone. On Friday evening the Bloomington members of the academy gave a banquet to the visiting members. On Saturday morning a number of members visited the cave region near Mitchell, Ind. The fall meeting of the academy is to take place at Indianapolis early in December.

MEM. Intended for publication and books, etc., intended for review should be sent to Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

YESTERDAY the dominant note was one of despair and defeat. To-day the dominant note shall be one of joy and victory.

Instead of hospitals reeking with pus and emptied by death, of operation after operation, when the roll was called, reporting a mortality of 40 per cent., 50, 75, 90, and even 100 per cent.—we have hospitals of immaculate whiteness and emptied by quick recovery, while the roll-call of operations reveals very few mortalities exceeding 10 per cent.; most of them having fallen to 5 per cent., 2 per cent., 1 per cent., and even small fractions of 1 per cent.

The story of Lister's work as recorded in his successive papers¹ is one of the most fascinating in all surgery. His earliest studies, from 1853 to 1863, were in physiology and pathology. Next he took up his researches on putrefaction (or as we should now say infection and suppuration) which led to his devising the antiseptic system. He was influenced to make these observations and experiments, which he applied with such signal success to surgical problems, by Pasteur's earlier researches. He always cheerfully acknowledged his debt to the eminent Frenchman. When a student in Paris in 1865 I knew Pouchet fils and was an interested spectator in the fight between Pasteur and Pouchet's father as to spontaneous generation. Lemaire's book on "Acide Phénique" (carbolic acid) was published in that same year.

Bacteriology did not exist as a science, but Pasteur, Lister and a few of the elect

¹ Lister's Collected Papers, 2 vols., Oxford, 1909.

in the upper realms of imagination saw the "germs" or "microbes" and firmly believed them to be the cause of infection. In 1900, at the age of seventy-three, Lister restated his earlier work² and illuminated it by many observations, experiments and drawings made in these early years, but first published fifty years after they were made.

If you wish to know the man, his fertility in devising new and convincing experiments, and his mental acumen in interpreting them "read, mark, learn and inwardly digest" that paper and use it as a model.

Paré in his naïve way tells us that he sought various applications which might "mitigate the pains [of his patients] and happily"—mark the word "*happily*"—"bring them to suppuration." That is the "laudable pus" of the pre-Listerian days. Lister, on the contrary, believing that infection and suppuration were evils, and avoidable evils, sought by various means to prevent them. But he says "all my efforts [during his work in Glasgow, 1860-69] proved abortive," and then adds significantly "as I could hardly wonder when I believed with chemists generally that putrefaction was caused by the oxygen of the air."

They and he were deeply impressed with the absence of putrefaction in simple fractures when the air and its oxygen had no access to the fracture. In my own lectures, as I often used to express it, "The very best antiseptic dressing is an unbroken skin." In compound fractures on the other hand when the air and its oxygen *had* access to the lesion, putrefaction always took place and caused a frightful mortality.

To test this supposed noxious influence of oxygen he devised many experiments, and among them one which may be well called

an "experimentum crucis." He filled four flasks one third full of urine (a quickly putrescible liquid) and drew out the necks to tubes one twelfth of an inch in diameter. All these tubes were *left open*. Three of these long necks he bent at various angles downwards; the fourth was left vertical upwards and also open. He then boiled all four flasks and awaited the result. The air and its oxygen had free access to the urine, being slowly drawn in during the colder night hours and driven out in the warmer daytime. Any supposed "germs" floating in the air, he reasoned, being heavier than air, could not climb up the slanting necks and fall into the liquid. In a short time the urine in the flask with the vertical open neck was decomposed, but the other three flasks, also with open necks but bent downward, *remained undecomposed for four years!*³

Could there be a more convincing proof that the oxygen had no influence whatever in producing putrefaction, but that it was due to living matter, "germs," in the air? It was a fine instance of the "scientific use of the imagination." "Germs" had been observed from time to time, but had not been generally accepted as the *vera causa* of putrefaction. The experiment just related was tried about 1867. The commonest, all-pervading germs, the staphylococcus and streptococcus, were not identified and proved to be the chief pyogenic (pus-producing) organisms until 1881, fourteen years after Lister had seen them so clearly with his mind's eye! Even in 1898 when I published my "Surgical Complications and Sequels of Typhoid Fever" I had to prove by elaborate citations of experimental and clinical evidence that the typhoid bacillus itself could cause suppuration, and that it

³ For a fuller account of this interesting experiment with references see my "Animal Experimentation and Medical Progress," pp. 204-205.

² *Brit. Med. Jour.*, 1900, II., 969.

had actually been observed in the circulating blood—for the past ten years or more a work of supererogation.

From Glasgow Lister went to Edinburgh (1869) as the successor of his father-in-law, Syme, and continued to experiment, to practise and to publish, but only a few were convinced, among them being Syme himself.

On the continent in the early 70's Saxtorph in Copenhagen, Thiersch in Leipzig, Volkmann in Halle, Nussbaum in Munich, and Championnière in Paris were among Lister's earliest and enthusiastic disciples. In America not much attention was paid to his work until he visited Philadelphia in September, 1876, to attend the International Medical Congress held in connection with the Centennial Exhibition. He was made president of the Section on Surgery and read a paper on the antiseptic method.

At that time I heard him and became fully convinced of the truth of the "germ theory" and of the value of his antiseptic method. When I went on duty at St. Mary's Hospital, October 1, 1876, I adopted the system (and was the first surgeon in Philadelphia to do so) and have never abandoned it. For me it changed surgery from Purgatory to Paradise.

But the reception given to his paper at our congress was anything but enthusiastic. The only surgeon who practically accepted Lister's method was that excellent St. Louis surgeon, John T. Hodgen. But so hazy were the general ideas of bacteria that in his own paper Hodgen speaks only of "germs" and "germinal matter" and had no idea of bacteriology as we now know it, for the science, and even its name, did not yet exist.

In the discussion of Hodgen's paper Hewson advocated his then well-known views on the value of dry earth as an "antiseptic." Canniff of Toronto rejected *in*

toto the germ theory of putrefaction. Frank Hamilton, of New York, while claiming extraordinarily good results from the open-air treatment and the warm-water treatment and other rival methods, "damned with faint praise" the antiseptic method. Kinloch, of Charleston, took the same attitude; Carpenter, of Pottsville, a Civil War surgeon, advocated chlorine in septic cases. Others sang psalms in praise of "perfect cleanliness" and said they "used both carbolic and salicylic acids, but *not* for the purpose of excluding germs." In the discussion on Lister's paper, Van Buren, of New York, doubted the safety of the spray in hernia and abdominal sections and Satterthwaite, of New York, rejected the germ theory of putrefaction.

In 1877 Girard, of the U. S. Army,⁴ became the enthusiastic supporter of Listerism.

In 1880 Markoe, of New York, while admitting the fine results of Listerism, spoke of "its somewhat arrogant pretension to be the true and only gospel of the surgery of wounds."

In 1882 Listerism was again discussed in the American Surgical Association. Briggs, of Nashville, endorsed Lister's method as "an epoch in surgery." Yet so limited was our knowledge of "germs" even then that warfare was waged only upon those "in the air." When these could be excluded he said "putrefaction . . . fails to occur." Yet Briggs qualifies his endorsement by saying that the

supremacy [of the antiseptic method as contrasted with other methods of treatment] . . . can not be demonstrated by statistics . . . and the present unsettled opinion concerning the proper status of his [Lister's] method is due in great measure to that fact.

⁴ Circular No. 3, Surgeon General's Office, August 20, 1877.

⁵ *Amer. Jour. Med. Sci.*, LXXIX., 1880, p. 305.

He emphatically dissented from the germ theory, and added

Carbolic acid is the keystone of the Listerian wound treatment. . . . The germ theory is at fault and furnishes a very unstable foundation for a system of wound treatment.

Moore, of Rochester, N. Y., proposed to exclude the air

by passing carbonic acid gas directly into the place where the operation is to be performed. In consequence of its being heavier than the atmosphere it preoccupies the space (!).

Campbell, of Georgia, "did not believe that bacteria . . . are the cause of that condition [suppuration]." The various men named were among our foremost American surgeons.

Lister's opponents entirely missed the great fundamental facts underlying the germ theory and Lister's antiseptic method, viz., that infection in all its various forms was always of bacterial origin—a wholly novel and momentous idea. Each form of infection, *e. g.*, tetanus, tuberculosis, typhoid, etc., it was soon proved, arose invariably and solely from its own specific kind of germ. Whether carbolic acid or any other germicide was the best was a mere matter of detail and not of principle.

In commenting on this discussion in which one prominent speaker is said to have asserted that Listerism "is now dead"—a remark I do not find in the *Transactions*—*The Lancet*,* a belated, but then, and ever since, a real convert, truly said

Surely it is too late in the day to contest the truth of the germ theory.

Yet even a year later (1883) at the American Surgical Association while B. A. Watson, of Jersey City, fully accepted Listerism, other prominent surgeons of Philadelphia, New York, New Orleans, Mobile, and other cities even declared in the discussion that no surgeon in their

* July 1, 1882, p. 1088.

cities or states used the method. McGraw, of Detroit; Dawson, of Cincinnati; Campbell, of Georgia; Prince, of Illinois, were "doubting Thomases," while Kinloch, of Charleston, and Nancrede, then of Philadelphia, advocated it.

But if its progress was obstructed in the United States, its foes in Great Britain were even more strenuous and for a season more successful.

In spite of the striking results in Glasgow and in Edinburgh Lister was looked at askance as "unorthodox."

In 1875 *The Lancet*† had said there is less antiseptic surgery practised in the metropolitan hospitals than ever there was.

At the Clinical Society‡ in a debate on antiseptic surgery in 1875, Mr. Maunier said with a fine, but, as the event showed, a too precipitate sarcasm:

Mr. Lister expects to prevent traumatic fever and . . . suppuration.

Timothy Holmes, while professing to have used antiseptics "for some years," declared his disbelief in Mr. Lister's theory with regard to "germs." *The Lancet's* editorial on the debate said it was "evident that few of the speakers either place faith in Lister's theory or carry out his practise in full."

After eight years in Edinburgh Lister was chosen professor of surgery in King's College, London, in 1877. This was the last stand of his opponents. The *British Medical Journal*, however, heartily urged the appointment of "the great surgeon of Edinburgh."

October 1, Lister gave his first lecture. He took as his subject "Bacteriology," though not using that title for, as Stewart said, "as yet the science had not a name."

† October 16, 1875, p. 565.

* *Lancet*, October 30, 1875, p. 628.

‡ The earliest instance of the use of the word "bacteriology" I have found is a quotation dated 1884 in the Oxford Dictionary.

Stewart¹⁰ gives a vivid account of the dreary days during which he and the other assistants whom Lister had brought with him from Edinburgh wandered in the wards of other hospitals "heavy with the odor of suppuration" while Lister's own small wards were filled with empty beds. Instead of the Edinburgh crowds of "500 eager listeners" their "hearts were chilled by the listless air of the 12 or 20 students who lounged into lecture at King's"—only 12 or 20 students!

But a month later the tide turned.¹¹ A case of fractured patella was admitted and in violation of all surgical precedent, for in that septic era to open a knee-joint meant too often the loss of limb or even of life, Lister boldly opened the joint, but with every antiseptic precaution, and wired the two fragments together. This elicited the remark from a distinguished London surgeon:

When this poor fellow dies, some one ought to proceed against that man for mal-practice.

But the man *got well*. Soon after this a case with an enormous malignant tumor of the thigh, which had been declined by other surgeons, came to Lister. He amputated the limb and,

the members of the staff and students visiting this interesting patient were astonished to find him in a day or two sitting up in bed and reading a paper, being free from pain and free from fever.

A little later Paget and Hewitt both refused to operate on a lady of social importance with a large tumor of the shoulder-blade. Lister operated in the presence of Paget and Hewitt and she recovered without suppuration, fever or pain.

Yet two years later still (1879) Savory, Thomas Bryant, Tait and Spence, while claiming to practise antiseptic surgery so far as strict cleanliness was concerned, de-

clined to subscribe to Lister's doctrines or to practise his method.

But the enthusiastic acclaim of the International Medical Congress in Amsterdam in that same year set the seal of approval of the profession at large. This may be said to be the date of the general acceptance of Lister's theory and Lister's method. London then capitulated.

In 1902, twenty-three years later, London made ample amends for its persistent early skepticism by a most generous outburst. The Royal Society, of which Lister had been president and from which he had received two medals, gave a banquet in honor of the jubilee of his doctorate. It was a most distinguished occasion and was made preeminent by a happy sentiment by Mr. Bayard the American Ambassador. Said he, addressing Lister:

My Lord, it is not a Profession, it is not a Nation, it is Humanity itself which, with uncovered head, salutes you.

Better, far better, such a eulogium than the peerage which had been already bestowed upon him.

Having now traced so imperfectly the fortunes of the germ theory, let us see the results of Lister's labors. The first results are his own, especially in Glasgow. There the horrible conditions he has so startlingly portrayed¹² should have made his wards a charnal house.

The mortality in the other accident ward was so excessive that it had to be closed. But in Lister's ward, separated from the other only by a corridor twelve feet wide, for the nine months "in which his antiseptic system had been fairly in operation . . . not a single case of pyemia, erysipelas or hospital gangrene had occurred."

The reason for his first attempt to apply

¹⁰ Wrench, p. 274 et seq.

¹¹ Wrench, p. 278 et seq.

¹² Lenoet, 1870, I., pp. 4, 40, and quoted in my "Animal Experimentation and Medical Progress," pp. 216-18.

the antiseptic system to man is well stated in his very first paper on the antiseptic method in 1867.¹² He wrote

The frequency of disastrous consequences in compound fracture, contrasted with the complete immunity from danger to life or limb in simple fracture, is one of the most striking as well as melancholy facts in surgical practise.

Well might he say this, for while simple fractures had practically no mortality, the mortality of compound fractures was all the way from 28 to 68 per cent.! In this, his first paper, he reported in detail eleven cases, with one death, an unheard of mortality of only 9 per cent.!

Thus encouraged, he attacked with an equally happy outcome abscesses, especially that bane of surgery in those septic days, abscesses of the spine. Be it observed too that fifteen long years were to elapse before the tubercle bacillus, the cause of such abscesses, was discovered by Koch (1882).

From accidental wounds it was but a step to deliberately inflicted wounds, i. e., surgical operations. Here too preventive antiseptics gave equally valuable results.

Lister, however, was much more given to establishing principles and methods than to statistics, but some of his early disciples published striking proofs of the value of his method by contrasting their former results with those which followed the acceptance of the germ theory and the adoption of Lister's antiseptic treatment.

Thus Dennis¹⁴ (1890) says that

The time is within my own recollection when, in Bellevue Hospital, amputation was immediately performed as a routine treatment to prevent blood poisoning, upon the admittance of a compound fracture; and this operation was considered by surgeons as offering to the patient the only chance of recovery.

This but corroborates what Syme had

already said in Edinburgh, that on the whole he was inclined to think

it would be better if in every case of compound fracture of the leg amputation were done without any attempt to save the limb.¹⁵

Dennis in his paper reported 681 cases of compound fracture, with only 19 deaths, a mortality of only 2.8 per cent., and only one of these 19 deaths was from sepsis, or 1/7 of 1 per cent.!

In Nussbaum's insanitary hospital in Munich, which Lister visited in the summer or autumn of 1875, he states¹⁶ that pyemia had been

very frequent and hospital gangrene which made its appearance in 1872, had become annually a more and more frightful scourge until in 1874 it had reached the astounding proportion of 80 per cent. of all wounds that occurred in the hospital, whether accidental or inflicted by the surgeon!

After trying every possible different method of treatment and still being unable to combat hospital gangrene and pyemia, Nussbaum finally adopted Lister's full antiseptic treatment and from the beginning of 1875 they had "not had one single case of hospital gangrene . . . and were doubtful whether they had had one case of pyemia"; and

the convalescent wards—which previously had been filled and overflowing constantly—Lister saw standing one after another empty, because patients, no longer affected with hospital gangrene, recovered much more rapidly.

In Halle Volkmann¹⁷ was operating in an extremely unhealthy hospital in small, overcrowded wards, with the toilet rooms opening directly into them and a large drain running directly underneath. It was so

¹⁴ "Lister's Works," II., pp. 249-51, *Brit. Med. Jour.*, 1875, II., p. 769, and Lindpainter (Volkmann's assistant), *Deutsch. Zeit. f. Chir.*, October, 1876, p. 187.

¹⁵ *Lancet*, 1867, I., p. 326 et seq. and II., p. 95, and Lister's "Collected Papers," II., p. 1.

¹⁶ *Medical News*, April 19, 1890, p. 423.

bad that it had been condemned to demolition. In the two years after his introduction of the antiseptic method in 1872, no single patient suffering from compound fracture had died either from the fracture or from a necessary amputation, nor was there a single death from secondary hemorrhage or gangrene. No case of blood poisoning had occurred for a year and a half, though sixty amputations had been done. Just before Lister's method had been introduced, of 17 amputations 11 had died from pyemia alone, a mortality of 65 per cent. Just after adopting Listerism the death rate of his amputations fell to 4 or 5 per cent.¹⁸

Hospital gangrene had been as it were "blown away" by a puff ("weggeblasen"); not a single case occurred. In Lindpainter's extensive tables of Nussbaum's cases one is struck, on glancing over them, to see how before the antiseptic method was adopted case after case is marked "died," "died," "died," and in the later tables, after its adoption, almost a uniform "recovered," "recovered," "recovered."

But the most striking testimony to the value of Lister's services to suffering humanity is not the statistics of the mortality in amputations, compound fractures, puerperal fever¹⁹ or in any single disease or operation, but in the enormous and successful enlargement of the beneficent field of surgery. In my own early days "before Lister" the common operations were

1. Amputations.
2. Ligation of arteries.
3. Removal of external tumors.
4. Lithotomy.
5. Tracheotomy, chiefly for croup and foreign bodies.

A few resections, colostomies, trephining

¹⁸ *Lancet*, 1881, II., p. 281.

¹⁹ See the extraordinarily interesting paper by J. Whitridge Williams, *Jour. Am. Med. Ass.*, April 22, 1911.

(when unavoidable) and herniotomies (for strangulation) were done. Ovariectomy was never done until the tumor had become so large as to threaten life, and even then operation was denounced by many as wholly unjustifiable, for it had a mortality as high as two out of every three cases. The head, the chest, the abdomen were ticketed "*Noli me tangere*" except in the rare cases when operation was absolutely unavoidable.

I used to wonder why the students in "Rab and His Friends" rushed to the amphitheater to get the best seats to see Syme amputate a breast—a so very common operation nowadays. But then I recalled the fact that even in my student days, when anesthesia was the rule, capital operations were rare. But in the preanesthetic days operations were far rarer. In the five years preceding the introduction of ether at the Massachusetts General Hospital the entire staff only performed in all 184 operations or three operations a month. When operations had become not only painless, but safe, then the number performed increased almost at a geometrical ratio, so that at present the numbers even of single operations by single surgeons—e. g., of ovariectomies, appendectomies, goiters—mount into the thousands. What is still more gratifying, the usual death rates of most capital operations in the pre-Listerian days of one patient in four, in three, or in two, or even two out of three (!) have been changed to one in twenty, thirty, fifty, or to even less than one life lost in one hundred or even one in two hundred operations!

It is impressive—most impressive—to call the list of only the most frequent and the most important of our present operations. Were Mott, Bigelow or Pancoast—all of whom I remember well—to come to life again they would wonder whether we were not stark crazy.

The following list I have made—*currente calamo*—on the instant.

Amputations are far *less* frequent. After a single battle in the Russian campaign, Larrey, Napoleon's great surgeon, performed not less than 200 amputations. To-day of 200 similar cases, sometimes even with wounds involving joints, the great majority would recover without amputation.

Formal ligations are far fewer.

External tumors of any size are now removed from all parts of the body without fear of erysipelas, which so worried Sir Astley Cooper before he operated on the king for a simple wen. The mere fact that any tumor is internal—inside the head, the chest, the abdomen, or the pelvis—has practically no influence on the decision whether it should or should not be removed.

Trephining—even for exploration—is frequent and *per se* involves slight danger, as in decompression.

Martin, of Berlin, has done over 1,000 ovariectomies, with a mortality of less than 2 per cent., and the Mayos from 1905 to 1914, inclusive (the only period for which I had the annual reports at hand), reported 609 cases with 5 deaths, or eight tenths of 1 per cent. Colostomy and enterostomy are frequent. Many thousands of hernias have been cured by operation, with practically no mortality; and if done early in strangulation, with slight mortality.

The new surgery of the head attacks tumors even of the hypophysis, punctures the lateral and the fourth ventricles with impunity, successfully extracts foreign bodies and in some cases relieves epilepsy and mental derangements.

In the neck simple goiters even of large size are removed, with a mortality of 1 and 2 per cent.; and laryngectomy is common.

In the chest, that very citadel of life, the heart itself is sutured for gunshot and stab wounds, saving one life out of two; the

esophagus is attacked for cancer and the removal of foreign bodies; large portions of the chest wall are removed for old empyemas, and the lungs can now be operated on at leisure, thanks to insufflation anesthesia.

In the abdomen, the various operations on the stomach, even to its total extirpation, are too many to name in detail; and with a success that is truly marvellous. We play with the intestines at will, opening them for foreign bodies and for drainage of the contents, removing what we wish, anastomosing them and short circuiting their contents. Tumors of the liver unless malignant are extirpated with a very low mortality and wounds of its substance are treated with success; gall stones and gall bladders are removed every day; the spleen is anchored, sutured or removed as we find best; the pancreas is no longer inaccessible; the kidney and the ureter, like the stomach, have their own list of operations far too long to rehearse.

In the pelvis the bladder is opened and partly or even wholly extirpated; the prostate removed; the uterus, the ovary, the tubes, the parovaria have a long list of life-saving, comfort-giving operations to their credit.

We suture and anastomose nerves; we suture and anastomose blood vessels even in the new-born, we criss-cross the circulating blood to prevent gangrene, and endo-aneurismorrhaphy has practically banished the Hunterian operation for aneurism and saved many a limb and life. We transplant skin and bones and joints, and even half joints, with success. To all these we have added the X-rays, the serum and vaccine treatment of many surgical disorders and are gradually throttling disease, sometimes at its very birth.

It almost takes one's breath away! Yet

it is an incomplete and ever-lengthening list! As Mumford²⁰ well says:

Daring has become conservatism; rashness has become common sense.

Practically our ability to do all these life-saving operations is the result of the researches, the experiments, and the achievements of Lister and his followers. Had antiseptics not made all operations, including the opening of the head, the chest, the abdomen, and the pelvis, safe, we should still be practising the very limited surgery of the 60's. Every year thousands whom now we restore to life and health would still be dying.

What now are the prospects of Listerism in the present horrible war? I have so far used the term "antiseptics." Asepsis is a later and a natural development of antiseptics and in civil life is of course preferable. The underlying and enduring principle of Listerism—the germ theory—is the same in both. There is no fundamental antagonism, but really a fundamental agreement between the two methods.

In the present war the surgeons whose papers I have so far read are almost a unit in favor of the antiseptic rather than the aseptic treatment of the wounded. They are right in my opinion, and the reason is plain. Comparatively few of the wounded reach hospitals with uninfected wounds. Mild wounds, and even in some cases severe ones, if they can be dressed soon after being inflicted, heal readily.

Sir Anthony Bowlby's²¹ striking description of the conditions in the trenches shows the difficulties very clearly:

In this trench warfare, if a man is hit, he often falls into filthy mud and water, which may be three feet deep or more. The trench is only two and a half feet wide. It is night, you can only grope about in the dark and can do no dressing of any kind, for you can't even get any clothes off in the dark, and in so cramped a space, and you

must try to get the man away to a "dressing station" half a mile distant, and thence to a field ambulance. If it is daylight, you can't get the man out of the trench at all, and he may have to be kept there for many hours, because he would certainly be killed if he were got out of the trench. And the water in the trenches is hopelessly polluted and soaks his clothes and his wound. Large lacerated wounds, and especially bad bone smashes, are so contaminated that it can never be possible to render them aseptic.

There is a noteworthy difference between the results of the wounds in the case of the trench-inhabiting soldiers and the wounds of sailors. The latter escape the dangers of the soil-infected trenches.

Sailors with the most severe type of wound, ragged, irregular, with uneven surface produced by herniated muscle and retracted severed fibers, usually have recovered promptly. Soldiers suffering from slight wounds have often had them contaminated with bacilli from the soil; particularly the anaerobes.

Hypertonic salt solutions like sea water are actually remedial by promoting the flow of lymph and serum in the wounded tissues.

But in a very large number of wounded soldiers, possibly the majority, hours and sometimes even days of delay ensure infection and then the surgeon is face to face with the one overwhelming surgical problem which has so far baffled all our efforts, viz., *how to transform a septic wound into an aseptic wound and keep it so, and at the same time how to combat the toxins already diffused throughout the body, but without doing harm to the patient himself.* Cheyne,²² Ehrlich, Wright and Carrel are all at work and it may be that the happy day when this, the most pressing and urgent problem in surgery, shall be solved, may come through this devastating war.²³

²⁰ *Lancet*, February 27, 1915, p. 419.

²¹ In the *British Medical Journal* of April 10, 1915, a most important article by Sir Almroth E. Wright on "Wound Infections" is begun. This should be very carefully read. On pp. 735-38 of

²² Keen's "Surgery," I, p. 76.

²³ *Jour. Am. Med. Ass.*, April 10, 1915, p. 1257.

Meantime Souttar²⁴ extols plenty of fresh air or better still of oxygen (our old supposed enemies in the 60's) and says

Men with wounds so foul that their presence in the wards could not be permitted, were placed, suitably protected, in the open air, the wounds being left exposed to the winds of heaven, covered only with a thin piece of gauze. The results were almost magical, for in two or three days the wounds lost their odor and began to look clean, while the patient lost all signs of the poisoning which had been so marked before.

Of tetanus in our Civil War there were in the Union army in all 505 cases and 451 deaths, 89.3 per cent. In the War of 1870-1 in the German army there were 294 cases and 268 deaths, or 91.1 per cent. In the present war there have been many cases in the allied armies in the west, but I have seen no numbers or percentages. In the German army, however, Czerny²⁵ says that the greatest danger to the wounded had been tetanus. Of 60,000 wounded Bavarians, 420 developed tetanus, which proved fatal in 240 cases (57.1 per cent.). The prophylactic value of the tetanus serum had been established, but its extensive employment was not always feasible.

This is a far larger percentage of cases than in our Civil War, or the Franco-Prussian War, but the mortality is far less—probably due to the even partial employment of the serum.

During the Civil War I never saw a case of "gas gangrene" which has been so prevalent and dangerous in the present war. The soil of Belgium and France, which has been cultivated and roamed over by animals for more than twenty centuries, is highly infected. Over ten different gas-producing bacteria have been found.

the same *Journal* for April 24, 1915, is another very important paper giving full directions for treatment. See also an interesting editorial in the *Journal American Medical Association*, May 23, 1915, p. 1765.

²⁴ *Brit. Med. Jour.*, March 20, 1915, p. 504.

²⁵ *Brit. Med. Jour.*, March 20, 1915, p. 521.

Sidney Rowland's experiment²⁶ well shows the virulent infection of the soil. Shaking up some of the soil from the trenches with some water, he injected a few drops into a guinea-pig and it was dead in eighteen hours with widely diffused gas gangrene. Soldiers have died from the disease in thirty-six hours.

Delorme has advised, as the germ is anaerobic, the injection of peroxide of hydrogen. Hartmann believes it needful to open the wounds freely and employ thorough irrigation with the peroxide²⁷—a most important procedure. Early treatment of infected wounds even in cases of gas gangrene resulted favorably in the hands of Cazin. Of 158 cases received even up to forty-eight hours after battle all recovered in spite of their serious nature. Among those received after four or five days' transportation the mortality reached 10 and even 20 per cent.²⁸

I have related the terrible mortality from typhoid in the Boer and the Spanish-American wars. The one bright spot in the present war is the conquest of typhoid. In spite of greatly increased numbers and of most unfavorable sanitary conditions in the trenches as I have shown, conditions which in former wars would have given rise to dreadful epidemics of typhoid, the following statistics in the British army officially given to Parliament on March 4, 1915,²⁹ show emphatically how well this scourge of every past campaign has been conquered. There had been only 606 cases in all: 247 among the partially (136) and fully (111) inoculated, with two deaths (0.81 per cent.), and 359 among the unprotected, with 48 deaths (7.47 per cent.), over nine times as many deaths proportionately! The one

²⁶ *Brit. Med. Jour.*, November 28, 1914, p. 913.

²⁷ *Jour. Am. Med. Ass.*, January 16, 1915, p. 259. See also Lawson and Whitehouse, *Brit. Jour. Surg.*, January 9, 1915, p. 444.

²⁸ *Jour. Am. Med. Ass.*, January 16, 1915, p. 259.

²⁹ *Brit. Med. Jour.*, March 13, 1915, p. 485.

reason for this splendid showing is the use of the antityphoid inoculation. If instead of its being only voluntary in the British army it had been compulsory as in our own army, the results would have been even better. And yet a blatant band of men and women both in England and our own country are doing all they can to oppose the use of this life-preserving remedy!

Let us now in conclusion take a general review of the surgical progress I have so inadequately sketched.

During the horrible days of Paré, Bell, Simpson, and our own Civil War there was still gradual improvement, but no *fundamental* change occurred for three centuries after Paré introduced the ligature and banished the boiling oil.

But about the middle of the nineteenth century, and especially in its last quarter, experimental research took the field. Everything that could be put to the test of accurate experiment in medicine and surgery was thoroughly investigated physically, physiologically, chemically, microscopically, biologically, bacteriologically. Laboratories were founded and research workers vied with each other in countless investigations. A flood of light was thrown upon every problem. And see the result in the long list I have just read to you! Medicine proper, obstetrics, all the specialties, sanitation and hygiene, furnish equally impressive calendars of progress—principally the result of experimental research.

Chief among these experimental researches were those of Pasteur (of whom I have said far too little for want of time) and of Lister. They inaugurated a wholly new era in surgery.

Then followed the battle for the germ theory and antiseptic surgery, ending in final victory. Meantime a new science, bacteriology, was born.

Next came the wide extension and appli-

cation of the new surgery to almost all the surgical ills that flesh is heir to. The wonderful results to both life and limb that I have recounted have naturally followed.

Even amid the disabilities and obstacles of war itself Lister's work has been a boon beyond price.

While the soldier and the scientist have been busy devising ever more frightful engines of destruction to maim and to kill, we surgeons have been equally busy devising means for saving thousands of lives and limbs in civil life, and even amid the carnage and savagery of war.

Surely our hearts should be lifted in gratitude to God for giving us such splendid powers of reasoning, experiment and research—all for the service of our fellow men.

W. W. KEEN

THE TWENTIETH ANNIVERSARY OF THE NEW YORK BOTANICAL GARDEN

The twentieth anniversary of the appropriation by the City of New York of 250 acres of land in Bronx Park for the use of the New York Botanical Garden will be commemorated at the garden during the week commencing September 6, 1915. Botanists from all parts of North America are invited to attend. The following program is planned:

Monday, September 6

Assemble at the Garden as convenient in the morning.

1:30: Lunch at the Garden.

2:30: Addresses of welcome and an account of the history of the Garden.

3:30-5:30: Inspection of a portion of the grounds and buildings.

5:30-7: Visit to the Zoological Park.

Tuesday, September 7

10:30-1: Session for the reading of papers.

1:30: Lunch at the Garden.

2:30-4: Session for the reading of papers.

4-6: Inspection of portions of the buildings and grounds.

Wednesday, September 8

Salt Water Day on Staten Island, for a study of the coastal flora.

Lunch at 1:30, with subsequent opportunity for scientific oratory.

Thursday, September 9

10:30-1: Session for the reading of papers.

1:30: Lunch at the Garden.

2:30-4: Session for the reading of papers.

4-6: Inspection of portions of the grounds and buildings.

Friday, September 10

Visit to the pine barrens of New Jersey, under the guidance of the Torrey Botanical Club.

Saturday, September 11

Visit to the Brooklyn Botanic Garden and an excursion to some Long Island locality.

Other excursions of more special character will be organized if opportunity offers.

THE CORNELL MEDICAL SOCIETY OF NEW YORK CITY

On February 4, 1915, twenty members of the teaching staff of Cornell University Medical College in New York City met at the college building and organized the Cornell Medical Society. The objects of this society, as stated in its constitution, are

to foster a better acquaintanceship among its members, to create an atmosphere of helpful and sympathetic criticism of the original work done in all departments of the Cornell University Medical College, and to promote the best interests of the college as an educational and research institution.

Four meetings, consisting of a scientific program followed by a smoker, are to be held each year in the months of October, December, February and April.

For the purpose of keeping in closer touch with the alumni of the college an annual day is to be observed in May, at which time

the regular college duties being suspended by vote of the faculty, the society shall conduct scientific demonstrations in the various laboratories of the college and in the hospital wards.

In the evening of this day the society, alumni and friends of the college shall give a dinner at

which the graduating class shall be the guests of the society.

The first regular meeting of the society this year was held in March and was attended by fifty members of the teaching staff; the second, held in April, was attended by sixty men, most of whom had become members.

The first annual day was held Friday, May 21. The regular classes, except those for the fourth year, were held, but a special program was prepared for the visiting alumni. About sixty alumni visited the college, some of them coming from a distance.

The first annual dinner was attended by 126. The president of the society, Dr. John A. Hartwell, presided and toasts were responded to by Drs. W. Gilman Thompson, Graham Lusk, Frank S. Meara, for the faculty; by Dr. Arthur M. Wright, class of 1905, for the alumni, and Mr. Douglas Palmer, for the graduating class.

The organization of such a society has fully justified the belief of its originators that it would serve a useful purpose. The meetings already held have demonstrated the advantages of bringing the members of the various departments into closer contact with the work being done in departments other than their own and of arousing in the alumni an interest in the progress which has been made since their graduation.

HOTEL RESERVATIONS FOR THE SAN FRANCISCO MEETING OF THE AMERICAN ASSOCIATION

THE Pacific Coast Committee of the American Association respectfully suggests that those who plan to attend the San Francisco meeting of the association during the week beginning August 2 should consider making their hotel reservations at once. A deposit amounting to ten per cent. of the anticipated total cost of the service should accompany the request for the reservation. This sum will be credited upon the hotel account.

The hotels on the appended list are comfortable and conveniently located. There are many other excellent hotels in San Francisco and vicinity, and printed information concerning them may be secured by addressing Mr.

Kirk Harris, Manager, Official Exposition Hotel Bureau, Flannery Bldg., Corner Kearny and Market Streets, San Francisco.

In selecting a location, it should be borne in mind that the opening session of the convocation week, for the presentation of the addresses of welcome and the response thereto, for announcements and for the president's address, will be held in San Francisco at 10:00 o'clock, Monday morning, August 2, in the Scottish Rite Auditorium, corner of Sutter Street and Van Ness Avenue; and that the social reception to visiting scientists and their friends on Monday evening and the general sessions of the association, including four lectures on Pacific-region subjects on Tuesday, Thursday, Friday and Saturday evenings, will be held in San Francisco. On Wednesday, August 4, the association will hold its sessions at Stanford University, near Palo Alto, thirty miles southeast of San Francisco. It is expected that a special train will leave San Francisco at a convenient hour on Wednesday morning for Palo Alto and return to San Francisco late in the afternoon. All other sessions of the week for the sections and participating societies will be held at the University of California, in Berkeley, where the main headquarters of the association for the week will be located. An information and service bureau will also be maintained in San Francisco.

Berkeley and Oakland are connected by several lines of electric railway (thirty minutes in transit; fare five cents). These cities are connected with San Francisco by rapid electric-car and ferry service operating every twenty minutes throughout day and evening (thirty-five to forty minutes in transit; fare ten cents), and with the exposition grounds by electric railway and direct ferry service at frequent intervals (fifty-five minutes in transit; fare fifteen cents).

SAN FRANCISCO HOTELS

(E, European plan; A, American plan)

Argonaut, 44 Fourth St. (E), 380 rooms, from \$1.

Cedille, 380 Eddy St. (E-A), 115 rooms from \$1; American plan from \$2.50.

Carlton, 245 Turk St. (E-A), 150 rooms, from \$1; American plan from \$2.50.

Clift, Geary and Taylor (E-A), 300 rooms, from \$2.50; American plan, from \$5.

Dale, 34 Turk St. (E), 180 rooms, from \$1.50. Exposition Inn, 2610 California (E), 110 rooms, from \$1.

Fairmont, California and Mason (E), 500 rooms, from \$4.

Golden West, 112 Powell (E), 190 rooms, from \$1.50.

Goodfriend, 245 Powell St. (E), 100 rooms, from \$1.50.

Granada, 1000 Sutter St. (E-A), 300 rooms, from \$2; American plan, from \$4.

Inside Inn, Exposition Grounds (E-A), 650 rooms, from \$1.50.

Normandie, 1499 Sutter (E-A), 200 rooms, from \$1.50; American plan, from \$3.50.

Palace, Market and New Montgomery (E), 500 rooms, from \$2.

Plaza, Post and Stockton (E-A), 282 rooms, from \$1.50; American plan, from \$3.50.

Stewart, 353 Geary St. (E-A), 250 rooms, from \$2; American plan, from \$4.

St. Francis, Geary and Powell (E), 1,000 rooms, from \$2.

Sutter, Kearney and Sutter (E-A), from \$1.50 American plan, from \$3.50.

Terminal, 60 Market St. (E), 165 rooms, from \$1.

Turpin, 17 Powell St. (E), 195 rooms, from \$1.50.

Von Dorn, 242 Turk St. (E), 150 rooms, from \$1.50.

Windemere, 776 Bush St. (E), 100 rooms, from \$1.50.

OAKLAND HOTELS

Key Route Inn, 22d and Broadway (E-A), 115 rooms, from \$1.50; American plan, from \$3.50.

Oakland, 13th and Harrison (E), 250 rooms, from \$2.

BERKELEY HOTELS

Bancroft, 2248 Telegraph (E-A), 56 rooms, from 50 cents.

Carlton, 2318 Telegraph (E-A), 108 rooms, from \$1; American plan, from \$3.

Claremont, Federal Realty Building (E), 175 rooms, from \$1.

Shattuck, Shattuck and Allston (A), 211 rooms, from \$1.50.

THE SCRIPPS INSTITUTE FOR BIOLOGICAL RESEARCH

The Scripps Institution at La Jolla, near San Diego, California, is to have its facilities

greatly improved. Miss Ellen B. Scripps has announced to the regents of the University of California her intention to give to the university during the next two years \$100,000 for further equipment.

A concrete pier a thousand feet in length will be built, at which can lie the *Alexander Agassiz*, the sea-going vessel owned by the institution and used exclusively for its work. Additional aquarium facilities will be provided, all planned to be useful for scientific purposes, but in part to be available for public educational objects. A salt-water pumping plant and settling basin are also to be provided, and living quarters for a group of scientific assistants, graduate students, etc.

The Scripps Institution has a site of 177 acres, with a half mile of ocean frontage, well-equipped laboratories, residences for the scientific staff, a good working library, and excellent equipment. The land was given by the city of San Diego, while for the most part the other equipment has come by the gift of Miss Scripps, who has created also an endowment of \$150,000 for its work. The state of California gives to the University of California \$7,500 per annum as a contribution toward the work of the institution, and Director William E. Ritter and his staff give their whole time to the research work. It is much resorted to also by visiting investigators and special facilities are arranged every summer for competent graduate students.

SCIENTIFIC NOTES AND NEWS

THE Albert medal of the Royal Society of Arts for the current year has been awarded to Sir J. J. Thomson, for his researches in physics and chemistry, and their application to the advancement of arts, manufactures and commerce.

THE gold medal of the first class of the Panama-Pacific Exposition has been awarded to Mr. Thomas A. Edison, for his storage battery.

DR. SIMON FLEXNER, director of medical research of the Rockefeller Institute, has been given the honorary degree of LL.D. by the University of Maryland.

THE University of Maine has conferred its doctorate of laws on Professor E. F. Ladd, professor of chemistry in the North Dakota College and food commissioner of the state.

A COMPLIMENTARY dinner was given at the Harvard Club of Boston on the evening of June 2 to Dr. Theobald Smith, who has resigned the George Fabyan professorship of comparative pathology in Harvard University to take charge of the department of animal pathology in the Rockefeller Institute. About 200 men, many of whom are prominent in the scientific world, were present, and President Lowell, who presided, said he had received a great number of letters and telegrams from all parts of the world. The speakers at the dinner were: Dr. Frederick C. Shattuck; Dr. William S. Thayer, of the Johns Hopkins University; Dr. Simon Flexner, of the Rockefeller Institute; President Emeritus Charles W. Eliot; Dr. William H. Welch, of the Johns Hopkins University; Dr. E. H. Bradford, dean of the Harvard Medical School, and Dr. Smith.

As the coming commencement at Amherst College marks the fiftieth anniversary of Professor B. K. Emerson's graduation from the college and the forty-fifth year of his work as a teacher, the forthcoming number of the *Amherst Graduates' Quarterly* will contain an editorial in appreciation of his work in geology. The article will be illustrated with a portrait of Professor Emerson, and with views of the old and new geological lecture rooms in which most of his college instruction has been conducted.

A TESTIMONIAL dinner was given, on June 8, in honor of Dr. Francis Clifford Phillips and Mrs. Phillips at the German Club, Pittsburgh, Pa., by one hundred former students and friends who desired to show their love and esteem upon the occasion of Dr. Phillips's retirement from active service as professor of chemistry in the University of Pittsburgh. Dr. Phillips, who is well known professionally because of his contributions to the chemistry of gases and his active participation in the interests of the American Chemical Society, has occupied the chair of chemistry at Pittsburgh

since 1875 and is retiring under the terms of the Carnegie Foundation. Among the speakers at the dinner were Drs. Walther Riddle, Albert E. Frost, R. B. Carnahan and J. H. James, and Professor Alexander Silverman. As an expression of their high regard for his devotion to the University of Pittsburgh, the old students of Dr. Phillips presented him with a check for \$1,000.

Dr. A. F. BLAKESLEE, professor of botany and genetics at the Connecticut Agricultural College, Storrs, Conn., has accepted the position of plant geneticist on the staff of the Carnegie Station for Experimental Evolution of the Carnegie Institution. His address after October 1 will be Cold Spring Harbor, Long Island.

Dr. ALLAN J. McLAUGHLIN, commissioner of health, has established in Boston a new department to be known as the division of hygiene and has appointed Professor Selskar M. Gunn of the Massachusetts Institute of Technology and Simmons College as its chief. Some of the duties of the division will consist in directing child welfare work, public health nursing, promoting traveling exhibits, public lectures and distributing health bulletins and pamphlets.

Dr. MATTHIAS NICOLL, JR., has been appointed assistant director of laboratories of the Department of Health, New York City.

Dr. SAMUEL H. HURWITZ (M.D., Johns Hopkins, '12), formerly of the Harvard Medical School, has been appointed instructor in research medicine in the George Williams Hooper Foundation for medical research of the University of California.

HERBERT R. COX is leaving the U. S. Department of Agriculture to become an associate editor of *The Country Gentleman*, with headquarters in Philadelphia.

THE Cancer Research Institute connected with the Charité Hospital at Berlin has been placed in charge of Professor F. Blumenthal, formerly Leyden's assistant, during Professor Klemperer's absence at the front.

Mr. J. E. CULLUM has retired from his position as superintendent of the Valencia

Meteorological Observatory, Cahirciveen, and the Meteorological Office has appointed Mr. L. H. G. Dines as his successor.

HERBERT M. WILSON, engineer in charge of the Pittsburgh Experiment Station of the United States Bureau of Mines, has resigned from the government service to become the director of a newly-formed organization to be known as the Coal Mine Insurance Association. Mr. Wilson was closely associated with Director Joseph A. Holmes in the inception and development of the Bureau of Mines. Early in 1907, when Secretary James R. Garfield added a technologic branch to the United States Geological Survey, Director Charles D. Walcott, of the survey, selected Joseph A. Holmes as chief of the new division and Mr. Wilson was appointed as his principal assistant. With the creation of the Bureau of Mines, Mr. Wilson became engineer in charge of the Pittsburgh station, a position which he has held ever since. The Coal Mine Insurance Association is a combination of ten American and British insurance companies that have associated themselves for the joint underwriting of coal-mine accident insurance.

UNIVERSITY AND EDUCATIONAL NEWS

Two anonymous gifts of \$150,000 and \$100,000 have been made to the Massachusetts Institute of Technology for dormitories. Funds with which to construct the mining building, some \$225,000, have been offered to the institute by Charles Hayden, '90, of Boston, and T. Coleman du Pont, '83, and S. Pierre du Pont, '90, of Wilmington, Del., past and present presidents of the du Pont de Nemours Powder Co. Coleman du Pont, it will be remembered, with his gift of \$500,000, made the purchase of the Technology site in Cambridge possible. Charles A. Stone, '88, and Edwin S. Webster, '88, of Boston, will provide a residence for the president.

Mr. JOHN R. LINDGREN, of Chicago, has bequeathed half his estate, valued at \$1,050,000 to Northwestern University, subject to certain life annuities.

By unanimous vote of the ten members present, the board of regents of the University of Minnesota adopted on June 10, the report of the sub-committee for the establishment of courses in graduate medical instruction at Rochester, Minn., in connection with the Mayo Foundation for Medical Education and Research, as printed in last week's issue of SCIENCE.

THE sum of \$30,000 has been given to Dalhousie University, Halifax, N. S., toward the endowment of a chair of anatomy, and announcement is made that in the near future the sum will be doubled.

MESSRS. G. A. AND H. H. WILLS have made an additional gift of £40,000 to the University of Bristol. Originally they gave £180,000 for the purpose of erecting additional buildings, but as the accepted tender exceeds that amount, they have now added £40,000.

THE department of geology of the University of Oregon will next year occupy new quarters in the large new administration building just completed. These quarters include a museum, a small classroom, a large laboratory in the basement, and an office, with probably an extra room for grinding apparatus, etc. The large general classes will be held in the new theater which is located in the same building. The geological laboratory is being equipped with a large new relief map of the state made by the Oregon Bureau of Mines and Geology and a set of Shaler-Davis physiographic models, besides other equipment.

DR. HERMON CAREY BUMPUS was installed as president of Tufts College on June 12. The speakers included President Lawrence A. Lowell, of Harvard University; Dr. Charles E. Fay, senior professor of the faculty of arts and sciences; Dean Charles F. Painter, of the Medical and Dental Schools, and Dr. Samuel P. Capen, of the United States Department of Education, president of the Tufts College Alumni Association. The inaugural address of President Bumpus was then given.

DR. JOHN CASPER BRANNER, who, when he assumed the presidency of Stanford University in 1913, announced that he would hold the office for only two years, and who recently

made this announcement effective by tendering his official resignation, has been persuaded by the board of trustees to continue in the office for another year. Dr. Branner reaches the retiring age of sixty-five this coming July.

DR. KENNETH L. MARK, associate professor of chemistry at Simmons College, Boston, has been placed in charge of the department of chemistry to fill the vacancy caused by the resignation of Professor J. F. Norris.

PROFESSOR JOHN PHELAN, of the University of Wisconsin, has been elected professor of rural sociology in the Massachusetts Agricultural College.

DR. WILLIAM M. SMITH, professor of mathematics in the University of Oregon, has been elected to succeed the late Professor J. J. Hardy at Lafayette College.

THE following changes have been made in the department of biology at Vassar College: Miss Cora Jipson Beckwith, assistant professor of zoology, promoted to associate professor of zoology; Miss Virginia Langworthy has been appointed assistant in botany, and Miss Alvalyn Woodward assistant in zoology.

At the University of Kansas, the following promotions have been announced: Assistant Professor Charles A. Shull to associate professor of plant physiology and genetics; Assistant Professor U. G. Mitchell to associate professor of mathematics; Associate Professor C. H. Ashton to professor of mathematics; Associate Professor A. J. Boynton to professor of economics; Assistant Professor A. H. Slus to associate professor of mechanical engineering.

DONALD BRUCE, formerly supervisor of the Flathead National Forest at Kalispell, Montana, has been appointed assistant professor of forestry in the University of California.

AMONG new appointments in the University of California Medical School are those of Dr. A. W. Johnson as instructor in laryngology, otology and rhinology; Dr. Olga Louise Bridgman as instructor in pediatrics and mental abnormalities of childhood, and Drs. Alfred E. Meyers, Howard E. Ruggles and Viola Belle Appleton, instructors in pediatrics.

Dr. A. E. BOWDITT, F.R.S., has been appointed director of the Graham Research Laboratory, the University of London, in succession to Dr. Charles Bolton.

Dr. A. CASTELLANI, distinguished for his researches on pathogenic bacteria, has been elected to a newly established professorship of tropical diseases at the University of Naples.

DISCUSSION AND CORRESPONDENCE

THE HALL OF FAME

THE most accurate expression of opinion of the people of the United States regarding

plorers, with missionaries; surgeons, with physicians; architects, with engineers. Musicians, painters, sculptors, etc., are designated as artists. The order is that of the number of members elected and of votes received. Three elections have been held, in 1900, 1905 and 1910. The number of candidates elected in each and all of these elections, the number of candidates who have received votes, and the percentage of the votes for each class are given in the later columns. A few scattering votes are not included. The last column gives the three highest votes cast in 1910 for candidates not yet elected.

Hall of Fame

famous Americans is to be found in the elections of the Hall of Fame. This institution has been organized with the greatest care, and, although it is probable that some worthy names are omitted, no unworthy person is likely to be elected. It appears, however, from the following table, that equal prominence is not given to different departments of human knowledge. Steps are being taken in the election of 1915 to remedy this difficulty. It is hoped that it will be successful. The urgent need of the change is the object of this paper. The class is given in the first column of the table. Rulers are included with statesmen; theologians, with preachers; judges, with lawyers; reformers, with philanthropists; ex-

The disparity in the numbers elected from the different classes is very marked. It is hard to believe that there are more famous authors and statesmen than in all other walks of life, or that there are twelve authors more famous than any American missionary, physician, engineer or business man. Apparently, the only reason that the number of statesmen elected was not greater than that of authors, was owing to the greater number of candidates. Among so many, the votes were scattered. The low position in the table of the physicians is noteworthy, and the absence of votes for the philanthropists after two were elected. Under the past system few men could be elected unless they were authors or

statesmen. Of the eleven writers of fiction, nine were elected, while, of the ten authors who wrote on serious subjects, only three were chosen. As the judges are men of literary tastes, they were more familiar with the work of the authors than of men in the other classes. The uniformity of the percentages in different years is very marked. This renders more conspicuous the relatively small vote for authors in 1900. If forty votes had elected in 1910, three of the six who were chosen would have been statesmen.

As the total number of votes cast was 8,645, three fourths of them were wasted; 2,050 votes would have given the forty-one men elected fifty votes each.

EDWARD C. PICKERING

May 25, 1915

A METHOD FOR IMBEDDING SMALL OBJECTS

It is quite a task to carry minute objects, as protozoa or eggs of sea urchins, etc., through the alcohols and get them safely imbedded in paraffin, without losing most if not all of them on the way. Lefevre¹ described a watch crystal designed by him for the purpose of imbedding small objects. This crystal had a small rectangular-shaped slit in the bottom about $12 \times 2 \times 3$ mm. This could be given a thin coat of glycerine and the objects placed in it by means of a pipette, and then the melted paraffin poured over them. When cold the paraffin can be removed with the objects imbedded in the small rectangular block which is easily trimmed for cutting. Lefevre suggested that the objects might be carried through the dehydration stages in the crystal, by drawing off the liquids with a pipette. This however, as later pointed out by Mayer, would remove the possibility of coating the crystal with glycerine and hence make it nearly impossible to remove the paraffin block when cold. Mayer² suggests an improvement by transferring the objects from absolute alcohol into small gelatine capsules. They may be cleared with xylol in the capsule and then melted

paraffin added, and the whole thing cooled in water. The water cools the paraffin and also dissolves away the gelatine capsule, leaving the objects imbedded in a neat cylindrical plug. There are some objections, however, to this method. (1) The great danger of losing the objects during the process of transferring them with a pipette from one reagent to another, and (2) the end of the paraffin cylinder at which the eggs lodge is rounded and hence difficult to cut. This latter obstacle was overcome by Metcalf's suggestion³ of reimbedding the objects in a Lefevre watch glass and hence removing the difficulty of having a round end to the mold. He found this successful with his preparations of *Opalina*. But even still there is great trouble attending the dehydration of these small bodies by transferring them from one watch crystal to another with a pipette or by drawing off the liquids with the pipette and leaving the objects in the dish. To make this task easier I suggest the following method which I have found successful with the eggs of sea urchins and *Cerebratulus lacteus*.

A heavy wooden base is obtained with holes bored in it of a proper size to permit ordinary homeopathic phials to stand upright in them. The size of phial I have found most convenient is about ten centimeters long and three in diameter. These phials are fitted with corks and then filled with the reagents desired in the process of fixation and dehydration. The next step in the preparation is to get some gelatine capsules (5×11 mm.) and give them a thin coat of shellac (shellac dissolved in 98 per cent. alcohol). This coat is best applied by immersing the capsules for a minute in a thin solution of the shellac and then standing them up on a flat surface to dry. Care must be taken to see that the capsules are completely immersed in the shellac solution so as to insure the coating of the inside surface. When dry take a fine needle and heat the point red hot and with it pierce a hole in the wall of the capsule about two millimeters from the top and another about three millimeters from the bottom. This is to permit a thorough drainage of the reagents through the capsule. A fine wire can now be fastened to the rim of

¹ *The Jour. of Applied Microscopy*, Vol. V., pp. 2080-2081.

² *Zeitschr. f. wiss. Mikrosk. u. mikr. Technik*, Bd. 24.

³ *Arch. f. Protistenkunde*, Vol. 13, p. 195.

the capsule and attached at its other end to the under surface of a cork fitting the phials containing the reagents. The wire should be of such a length as to just permit the flow of the reagent through the two holes in the capsule when the cork is tightly fitted into the phial. To place the objects to be imbedded in their shellac-gelatine container I take a glass rod drawn out to a desirably fine point and dip it into a celloidin solution of gelatinous consistency (12 per cent. celloidin in 80 per cent. alcohol). A little of the celloidin will cling to the point of the rod, which is then allowed to come in contact with the stock of material to be dehydrated, in my case sea urchin eggs. A number of these eggs will cling to the sticky mass, which can be easily washed into the bottom of the prepared capsule. Then it is a simple matter to run the eggs through the reagents. One only has to transfer them by taking the cork from one phial and carrying it over to the next. They may first be washed in water and weak alcohol as the outside coating of shellac is insoluble in water and weak alcohol and hence prevents the dissolving of the gelatine. By the time 95 per cent. alcohol has been reached the shellac has dissolved away, but in this medium the gelatine is insoluble and so the objects are safely retained. They can be cleared in xylol and left in melted paraffin to permit thorough infiltration. When ready for the final imbedding one can easily hold the capsule out of the phial by means of the cork to which it is attached, and slowly drop melted paraffin into the mouth of the capsule with a pipette, all the time blowing on the capsule to hasten cooling. The paraffin will cool quickly and plug up the two drain holes and form a solid cylinder. Then one may detach the capsule from the wire and place it in water where the gelatine soon dissolves, leaving a solid form of paraffin with the eggs imbedded in the end of it. To assure being able to see the eggs one may place the capsule during the dehydration process for a few minutes in borax carmine, which will stain the objects red and thus enable one to see them through the rest of the process. After being sectioned the carmine may be decolorized with acid alcohol.

This method removes the danger of losing the objects when transferring them from the various solutions with a pipette. The drop of celloidin assures their being held in a compact mass and in most cases raises the bodies far enough from the floor of the capsule so that the rounded end may be sliced off without cutting away the objects and thus give a flat surface to section from. To be absolutely sure of this one may prepare his capsules with flat bottoms before imbedding. This is done by cutting off the round end and attaching a flat sheet over the bottom with liquefied gelatine and cementing it with shellac. Or again after the objects are imbedded in the round end of the capsule they may be sliced out and reimbedded in a Lefevre watch glass as suggested by Metcalf.⁴

This method will, I am sure, prove useful to any one having much imbedding to do, of minute objects. It has the advantages of being extremely simple, rapid and reliable.

BALTIMORE

SOME REASONS FOR SAVING THE GENUS

As there seems to be something of a lull at present in the vexatious controversies over zoological and botanical nomenclature, I fear that I run the risk of being branded as a wanton mischiefmaker if I seek to reopen the subject in these columns. However, no one can say that the evils complained of are likely to diminish much in the near future. And furthermore, it has always seemed to me that one of the most flagrant of these evils has scarcely been complained of at all, at least in the public discussions regarding nomenclature. Complaint has been made, bitterly enough at times, of the constant changing of specific names, resulting from a rigid enforcement of the law of priority. In reply, it is contended, and with some plausibility, that such changes will cease automatically when the antiquarian has finally accomplished his task.

But there is another perennial source of

⁴ Loc. cit.

confusion which has not received adequate attention. Apparently it is regarded as quite unavoidable, or perhaps it is not commonly thought of as a difficulty of nomenclature at all. I refer to the continual changing of names that results from the subdivision of genera. Who has not experienced the peculiar feeling of mingled dismay and exasperation which follows the discovery that some long-familiar genus, whose species are to most of us scarcely distinguishable as species, has been split over night into a half dozen new genera? In place of the familiar collective group—*Jonesia*, let us say—we now have *Neojonesia*, *Eujonesia*, *Pseudojonesia*, *Megajonesia*, *Microjonesia* and *Heterojonesia*, or perhaps a set of names that no longer even suggest the former unit. And if we look for the distinctions upon which these subdivisions are based, we commonly find that the differences are very trifling indeed in comparison with the many and detailed points of resemblance between these various groups.

Let me not be misunderstood. Differences, however slight, ought when constant to be recognized and in some way incorporated into the taxonomic structure. "Splitting," so far as it is based upon the detection of such differences, is a legitimate and indeed inevitable process, if systematic zoology is to progress. Why, then, should one object to the indefinite subdividing of genera? And is it not highly presumptuous for one who is not a taxonomist at all to be offering his opinions as to what constitutes a difference of generic value?

Taking up the first of these questions, it must be borne in mind that in the Linnean system of binomial nomenclature the generic name plays two quite distinct rôles. One of these is to designate a taxonomic group, supposed to be intermediate between the family and the species. The other is to form the first half of the "scientific" name of each species within that group. It is for this reason that the changing of a generic name is so much more disconcerting than is changing that of a family or order. And this is why, in the writer's opinion, such splitting as we have just recognized to be inevitable should be done

within the limits of the genus, either by the creation of "subgenera," or, if necessary, by the establishment of wholly new categories between the genus and the species.

As regards the second point above raised, I should indeed feel much diffidence in offering my opinion on this subject were there even an approach to unanimity in respect to what constitutes a character of generic value. It is frequently said that the genera of Linneus are the families of to-day, while it is doubtless also true that some Linnean species constitute present-day genera. Even now, the inclusiveness of the concept genus varies enormously in different groups of organisms. In general, those groups which have been studied most intensively by systematists are doubtless on the whole those in which the concept has acquired the most restricted meaning. This narrowing down of the inclusiveness of the genus is thus an evil which may seem to be progressive and incurable. Its logical outcome is the creation of a separate genus for each species, in which event the two categories will become identical. When that has come to pass, no further changes of nomenclature will be possible, and we shall have attained the much desired stability. At the same time, all verbal clues to the nearer kinships between species will have been lost, and biology will be to that extent poorer.

Taxonomists are too prone to regard this whole question of nomenclature as one which is exclusively their own. The intrusion of an outsider into the fray is likely to be hotly resented. I remember venturing, several years ago, to express some of the above views in a letter to a well-known authority on one of the larger groups of invertebrate animals. No reply whatever was made to the line of reasoning set forth by me. I was merely "squashed" with the rejoinder that I had sufficiently wide experience in describing species. I would see things in a different light—a statement which is possibly true, though proving nothing as to the point at issue. Our taxonomic brethren have so long been

as "poor relations" by those who complacently believe their own studies to be concerned with real biology, that this sort of a "tu quoque" is now and then to be expected. But such "class consciousness" should be laid aside, and the question candidly considered whether the entire biological profession, or indeed society at large, does not have a proprietary interest in taxonomic names. A very little reflection will show that this is true. The case is not at all dissimilar to that of a coal or railway strike in which the rights of the public—the chief sufferers—are entirely ignored by the disputants. And we may say with equal justice that the chief sufferers from an unstable system of nomenclature are not the taxonomists—whether "splitters" or "lumpers"—but that host of unfortunates who are under the constant necessity of using these names, while having no share in their creation or transmutation.

Returning to the subject of generic names, it must not be supposed that the only evil resulting from this progressive "splitting" is the mere inconvenience of our having to learn new names as fast as the old ones are displaced by accredited authorities. This, indeed, is bad enough, but there is an even more harmful result which, I think, deserves further emphasis. I have spoken above of generic names as verbal clues to the nearer kinships between species. These clues lose their value in proportion as genera are made less and less inclusive. Let me illustrate. We have, on the coast of southern California, three common species of "ice-plant," which differ from one another strikingly in structure, appearance and habits of growth. When these three species of *Mesembryanthemum* have been assigned (as some day they will) to the separate genera *Smithia*, *Johnsonia* and *Macarthyana*, those of us who are not systematic botanists may no longer think to look for the fundamental resemblances among these plants which appear to have so little in common. Again, I recently learned that a certain little straggling plant, with a yellow flower, which abounds along the beaches at La Jolla, is in

reality an *Ænothera*! Who will say that I added nothing to my knowledge when I affiliated this little plant with that well-known genus? But how many such clues to relationship will be left when the genus-splitter has finished his work?

The question raises itself whether the detection of resemblances in nature is not as important as the detection of differences. Is it not largely this unity in variety—or variety in unity—which fascinates the true nature-lover, be he an amateur collector, a beginning student or a professional biologist? And it can hardly be denied that the extent of our recognition of such unity is greatly influenced by the names which we find applied to things.

Fortunately, I am able to cite, in support of my present contention, the words of a high authority in the field of systematic zoology. W. H. Osgood,¹ in justifying his extensive use of subgenera, writes that those who object to this procedure "must necessarily recognize more and more groups as genera until the distinction between the genus and the species becomes so slight as to be of little taxonomic value, while at the same time the gap between the genus and the group of next higher rank is correspondingly increased." Such a tendency, he says, "actually operates to reduce the number of categories of classification between the subfamily and the species, and this results, not in an improved and more discriminating system of classification, but one with fewer groups and fewer possibilities for the indication of relationships." Again:

The use of subgenera provides a means of adjusting the differences usually existing between the general zoologist and the specialist. The generic name answers all the purposes of the general zoologist while the specialist may use as many subgenera as he desires and meet all the requirements of discriminating classification. This also operates to conciliate the amateur, whose outcries against the continual changing of names by specialists will thereby be lessened. Although these protests are

¹ "Revision of the Mice of the American Genus *Peromyscus*," U. S. Department of Agriculture, North American Fauna, No. 28, 1909 (citations from page 25).

often unreasonable, the specialist should remember that his scheme of nomenclature to be truly successful must answer the purposes of others as well as himself. If the specialist conservatively retains well-known and natural generic groups he may segregate subgenera indefinitely without retarding the progress of exact taxonomy, and, at the same time, without interfering with the less exacting needs of the general zoologist and the amateur. Moreover, further advantage is found in the fact that the percentage of legitimate changes of names that would confront the much-abused amateur would be greatly reduced; for changes of subgeneric names on account of pre-occupation and other causes would in most cases concern only the specialist.

I could name at least one other leading mammalogist who heartily concurs in the views quoted. So the issue is not exactly one between the "general biologist" and the systematist, but is rather one between two different types of systematists. In this conflict the "general biologist" should, I think, lend his regard for the interests of the scientific public.

F. B. SUMNER

SCRIPPS INSTITUTION FOR BIOLOGICAL RESEARCH,
LA JOLLA, CALIFORNIA

THE PROBLEM OF THE PRIBILOF ISLANDS

THE U. S. Bureau of Fisheries has issued an elaborate and handsomely illustrated report on Alaskan conditions,¹ the work of Mr. E. Lester Jones, its deputy commissioner, embodying the results of his investigations during the past summer. The major portion of this work lies outside of the writer's field, but that portion which treats of the fur-seal islands suggests a few words of comment from one who has given much time and attention to their problems.

Mr. Jones thus sums up the Pribilof Islands problem:

If moral, intellectual and general conditions are to be improved; if the business of the islands is to be carried on along business lines (and surely the proposition of these islands, including the fur-

¹ Report of Alaska Investigations in 1914; Department of Commerce, Bureau of Fisheries, by E. Lester Jones, Deputy Commissioner of Fisheries, December 31, 1914.

seal and the fox herds, is largely commercial), then the situation must be viewed from an entirely different standpoint than hitherto; for the returns the government is to receive from its investment warrant the expenditure of a sum of money large enough to give the officials of the government and the natives civilized surroundings, and to provide adequate means and necessary facilities to accomplish a proper administration of the affairs of these islands.

This summary follows the discussion of a long series of topics such as immorality and drunkenness among the natives; inadequate and unsanitary housing facilities; unsatisfactory schools; inadequate and ill-adjusted wage schedules; insufficient occupation for the natives; need of additional government agents; better facilities for unloading vessels; stricter landing regulations, etc., the conditions respecting these matters being found to be "deplorable." The keynote of the whole discussion is that the government officials and natives resident on the fur-seal islands are without civilized surroundings and that it is the duty of the government to relieve the situation.

In a residence on these islands for purposes of investigation of more than twelve months' duration distributed over five seasons and a period of seventeen years I failed to discover this lack of civilized comforts noted by Mr. Jones. On the contrary, I enjoyed such comforts to a marked degree, surpassing that which I have found possible at times in home communities of a much larger and more accessible type. I have been quartered in all of the government and company houses on each of the two islands, and there never was a time when I could not get a hot bath for the asking, and on St. Paul Island is the only place where I have ever experienced the delicate attention of having an attendant light a fire in my room before getting up in the morning. These things are specifically mentioned because Mr. Jones specifically notes the absence of bathing facilities and of janitorial service as among the deprivations to which the government officials are subjected.

Speaking of more important matters—morality, temperance, sanitation and personal cleanliness among the natives—if the summer of

1914 found them in the unsatisfactory condition which Mr. Jones emphasizes, the season was certainly an exceptional one. For this there was a very simple reason.

At the close of the season of 1912 the efficient and long-experienced representatives, four in number, who had had charge of the affairs of the government and natives for periods ranging from ten to fifteen years each, were ruthlessly displaced. They were under civil service protection but their discharge was effected by the simple expedient of omitting their salaries from the appropriation bills. In their places were substituted two underpaid caretakers, one for each island. It was ostensibly a matter of economy. Congress had just enacted a law which suspended land sealing for five years. There was no need to continue the full force of expensive agents. The sealing plant and natives could get on by themselves for a time. Such was the argument. No result other than demoralization of the service could have been expected. Mr. Jones himself admits the cause of the trouble by recommending the appointment of a superintendent and assistant superintendent for each island at salaries commensurate with the need of good men, these officers to replace the present caretakers. This is in effect a recommendation to restore the conditions of 1912 and prior to that time. It will be well if the government heeds this suggestion. Even then it will sorely miss the mature experience and capacity of the agents it turned off.

Other criticisms made by Mr. Jones, regarding inefficiency of schools, lack of occupation for the natives, delay in handling cargo, and the like, are referable to the same cause. The government weakened its island force and is suffering the inevitable consequences. Given an efficient management and the "deplorable" conditions will quickly disappear. These conditions have not, as Mr. Jones states, "existed on these islands for years." The men he found occasion to dismiss had been in charge but one season.

Mr. Jones's discussion does not touch the real problem of the Pribilof Islands at all. This has to do with the operation of the fur-seal law of 1912 which suspended land sealing.

As noted, this gave excuse for the dismissal of the responsible agents. It deprived the natives of their regular occupation and means of livelihood, making them the dependent wards of the government. Mr. Jones in a speech to the natives on St. Paul Island, which he includes in his report, calls their attention to the fact that they were receiving from the government supplies to the value of three hundred dollars a year for four days' actual labor. Idleness leads to viciousness and fosters all of the unsatisfactory conditions enumerated.

Mr. Jones does not discuss the fur-seal situation, because this matter was in the hands of a scientific commission. He passes it over in silence. At least twelve thousand killable fur seals, with skins worth approximately fifty dollars each, went to waste on the hauling grounds of the Pribilof Islands in the season of 1914 under Mr. Jones's very eyes. It was a striking thing and deserved notice in his report, especially since the report of the scientific commission has apparently not been published. In comparison with this great loss which the government sustained on the fur seal islands in the summer of 1914, the matters of which Mr. Jones does treat pale into insignificance.

The blue foxes, however, are touched upon by Mr. Jones. These are an important, if subordinate, element in the government's fur industry. The outlook for these animals on St. Paul Island is said to be "bright." On St. George Island, "owing to some fault in feeding," it was not so good, but new breeders were to be brought over from St. Paul to take the place of those which died. The advisability of selling foxes "on bids" to those wishing to engage in fox farming is gravely discussed.

This is all very interesting, but very superficial and inadequate. The blue foxes were left to starve, just the same. The herd has grown to depend largely upon the carcasses of the fur-seal killing grounds for its winter food. Commercial killing had been cut off and the killing fields were bare. The government had taken no steps to replace this food. That was why the foxes on St. George died. They died also on St. Paul. The foxes are cannibalistic under shortage of food, the strong eat the weak,

the old the young. These tragedies occur in the warrens and are not conspicuous. There is simply a diminished herd in the spring. It will be but a fragment, a remnant, of a fox herd which the government will possess when the futile law suspending seal killing has run its course three years hence. The irony of the situation lies in the fact that the foxes, thus cruelly and improvidently treated, yield skins which in 1912 sold as high as one hundred and fifty-eight dollars each. Had Mr. Jones recommended that the government send up beef from Seattle or San Francisco to feed these foxes over the winter, his recommendation would have been one which the government could well afford to consider favorably.

No; the problem of the Pribilof Islands is not one of bringing the comforts of civilized surrounding to the officials and natives. It is rather one of applying common horse sense to the administration of the fur-seal industry. The present ill-advised and wasteful law should be repealed or amended. The fur-seal herd stood ready to yield six hundred thousand dollars worth of sealskins in 1914. Mr. Jones might have had the satisfaction of seeing them taken and their value covered into the treasury. The law prevented it. He has no comment to make. Incidentally the taking of these skins would have given useful occupation to the natives, restored to them and to the foxes their wonted food, and richly earned for the officials and natives of the islands any degree of generous treatment at the hands of the government.

GEORGE ARCHIBALD CLARK

STANFORD UNIVERSITY,
CALIFORNIA

A SAFE METHOD OF USING MERCURY BICHLORIDE
FOR THE ANTISEPTIC OF WOUNDS OF
LARGE SURFACE

SOME years ago the writer developed what appears to be an entirely safe and very effective method of making antiseptic extensively lacerated areas. Briefly (and I am afraid in very untechnical language) the results of the experiments were as follows:

1. The reason mercury bichloride is dangerous is that it combines with the albumen (!)

of the exposed surface of the wound. For example, if a liter of 1 to 1,000 solution be used to bathe a wound of extensive surface, all the bichloride (roughly speaking), amounting to a gram in weight, is precipitated out of the solution and remains in the wound in the form of albuminate of mercury, which is later redissolved and absorbed. Hence the subsequent poisoning.

2. If, however, the wound be first bathed with a solution having a stronger affinity for albumen than mercury (a dilute solution of chloride of zinc, and other metallic chlorides, was found to give good results) especially one which gives a granular but coherent compound, and is then bathed with water and finally with a 1 to 1,000 solution of mercury bichloride, not left in too long, the antiseptics is perfect and there are no bad after-effects. The albumen having combined with the zinc to form albuminate of zinc, seems to be no longer able to quickly combine with the mercury.

3. That mercury bichloride is a much stronger antiseptic relatively to other antiseptics than is stated in the text-books.

4. That antiseptics mixed with oils or fats, vaseline for example, lose their effectiveness almost entirely.

The importance of the matter at the present time (there is no known way of effectively disinfecting wounds received in battle) and the fact that the results were forwarded to the *Lancet* and *Nature* some years ago but not printed or acknowledged is my excuse for asking you to publish this rather crude and incomplete note.

REGINALD A. FESSENDEN

BROOKLINE, MASS.

A SOLAR HALO

TO THE EDITOR OF SCIENCE: On the morning of May 20 an interesting solar halo was observed in the vicinity of Philadelphia, which was sufficiently unusual to be worthy of record. When observed between 11 A.M. and noon the appearance was as indicated in the accompanying diagram. A and B were two prismatic circles concentric with the sun, of radii (meas-

ured with a sextant) $22^{\circ} 10'$ and $46^{\circ} 45'$, respectively. *C* was the whitish parhelic circle, of radius $20^{\circ} 5'$ corresponding to the solar altitude of about 70° . At the intersection of the circles *A* and *C* there were slight increases of intensity but no conspicuous parhelia. *D* and *E* were much fainter arcs intersecting the parhelic circle at the point opposite the sun. If prolonged they would have been approxi-

FIG. 1.

mately tangent to the 22° circle. The phenomenon was first noticed at 11 A.M. and faded soon after noon.

QUOTATIONS

THE CONDITIONS OF INDUSTRIAL ACCIDENTS

THE enactment of laws in various states on workmen's compensation for injuries has aroused increased interest in the statistics and physical and psychic conditions of industrial accidents. The total number of these accidents is almost appalling. The lowest

estimate places the fatal accidents to adult workers in the United States at 35,000 a year, with an additional 1,250,000 non-fatal accidents. The Massachusetts Industrial Accident Board, on the other hand, placed the number of workers killed by accident yearly at 75,000, which apparently includes not only adults, but also workers of all ages, while the number of injured of the same classes was placed by this Massachusetts authority at 8,000,000 or over. An earthquake in a foreign country that kills half this number of persons and maims one fiftieth of those injured in our United States industries is spoken of as catastrophic.

Among the interesting elements of these accident statistics is the fact that a greater proportion of accidents occurs on Monday than on any other day of the week. Accidents are said to be due often to fatigue. As, after the day of rest on Sunday, workmen should be less fatigued than on other days, some other factor must be sought to explain this feature of the statistics. It has been suggested that the "blue Monday" accidents are really due to the fact that workmen take more spirituous liquor on Sunday, and thus become unnerved and more liable to accidents during the following twenty-four hours. There is, perhaps, something in this contention, though it has been disputed. In the Massachusetts Industrial Accident Board Reports, in which the official figures are given, there is scarcely more than one twentieth more accidents on Monday than on Tuesday, while Tuesday is not much above the average in the number of accidents reported for other days. Saturday, of course, shows a noteworthy reduction, because of the half holiday in some trades.

By far the larger number of accidents occur at about 10 A.M. and 3 P.M. This fact is confirmed by the reports of two state boards, Washington and Massachusetts, which have secured rather careful records. As they represent the extremes of the country, the conclusions from their statistics would seem to be incontrovertible, though the fact is not what might naturally be expected. The State

of Washington Industrial Commission¹ says, "These results seem to disprove the theory that fatigue is the prominent cause of accidents, because accidents are here shown to happen at the hours when the workmen are least fatigued." On the fatigue theory it might naturally be expected that most accidents would happen after 11 A.M. and 5 P.M. The actual hour of the high point of curve of accidents shows how important are the facts and how necessary of proof the theories.

After much discussion, the tendency to speed up employment has been incriminated, as the predisposing conditions for the occurrence of accidents. This desire comes over the workman when he is not yet fatigued, but has been employed for several hours. He starts the morning's work "cold," and as he warms to his work, the danger of mischance because of haste becomes greater. Just when the speeding up reaches a climax in the morning hours, most accidents happen. The same thing is true in the afternoon. Workmen feel sluggish after their lunch, but after an hour of work warm up again, and by about 3 o'clock they are doing their most rapid work, and are at the same time more subject to accident.

With regard to accidents among children, however, there is no hour of maximum. Accidents occur at all times, and they are comparatively much more frequent among children than adults. The United States Bureau of Labor reported that "there is clear evidence of great liability to accident on the part of children. Though employed in the less hazardous work, their rates steadily exceed those of the older co-workers, even when in that group are included the occupations of relatively high liability." This was said with regard to the southern cotton mills, but the same thing is true of practically all industries in which children are employed.

The results of these accidents come to the physician. We are devoting much time to the prevention of disease, and we should be ready to give attention also to the prevention of injury. Virchow used to say that the ideal

¹ Report of State of Washington Industrial Commission for 1912, p. 178.

function of the physician, besides that of reliever of human ills, is to be the attorney of the poor for the prevention and relief of social ailments, and, above all, the prophylaxis of their physical consequences, whether in lowered health or in maiming injuries.—*Journal of the American Medical Association.*

SCIENTIFIC BOOKS

The Ants of the Baltic Amber. By W. M. WHEELER. Schriften der Physikalisch-ökonomischen Gesellschaft zu Königsberg. LV. (1914.) Pp. 142.

Among the very numerous writers who have discussed the structure and habits of ants, few have had anything to say about the early history of the group, as shown by the paleontological record. Large collections of fossil ants have remained for many years in museums, unnoticed by students, who seem never to have conceived that the record of the past would throw any light on the present. As long ago as 1868, Gustav Mayr published a very important paper on the ants of Baltic amber; in 1891 Emery gave an account of fourteen species found in Sicilian amber, and at different times other writers have described fossil ants. Thus the total numbers of recorded species of fossil ants is well over 300, but many of these are very imperfectly known, and probably assigned to the wrong genera. The materials collected and then neglected have been very extensive, and in particular those from Baltic amber and from the Florissant shales in Colorado, numbering thousands of specimens, have invited a complete revision of paleomyrmecology. It is very fortunate that the rich collections from these two localities have fallen into the hands of Dr. Wheeler, who has undertaken the great task of setting them in order. The first section of this work, on the ants of Baltic amber, has now been published. Dr. Wheeler had the loan of the whole collection from the Geological Institute at Königsberg, as well as that of Professor R. Klebe, together with some smaller lots, the total number of specimens examined being 9,527. Of one species alone, *Iridomyrmex gossepti*, he saw 4,539 individuals. Up to the

time of Wheeler's studies, 24 genera and 52 species were known from Baltic amber; he now adds 21 genera and 40 species, in addition to revising those already known.

No ants are known from the Mesozoic; one or two recorded as such prove to belong to quite a different group of Hymenoptera. The oldest fossil ants, by far, are those described by Scudder from the Eocene of Green River and White River in Wyoming and Colorado. These, unfortunately, are poorly preserved, and afford very little information. The beds along White River near the Colorado-Utah boundary are certainly Eocene and not Oligocene, as has repeatedly been stated, apparently from confusion with the White River group of Oligocene beds from which mammals are obtained. Further collections from the insect-bearing Eocene rocks of the west are much to be desired, as well as a more complete examination of those already obtained, for there is a chance to discover very important entomological facts. In Europe, the Lower Oligocene contains the earliest ants, but includes the Baltic amber, as well as the beds at Aix in France, and probably the Gurnet Bay deposit in the Isle of Wight. This last, from which I have recently described a number of ants (*Dolichoderus*, *Leptothorax*, *Ecophylla* and *Ponera*) is perhaps later than the amber. The Middle and Upper Oligocene and all three divisions of the Miocene (the latter including the important localities (Eningen in Baden, Radoboj in Croatia and Sicilian amber) have afforded fossil ants in Europe, and there is a single Italian locality assigned to the Lower Pliocene. Between the last and the Pleistocene is a blank. The supposed Miocene record from Spitzbergen is to be deleted, the specimen being the abdomen of some insect, and wholly unrecognizable.

Thus it appears that our first real knowledge of fossil ants begins with the amber, probably at least two million years ago. What development has the group shown in all this long time? To what extent are the remarkable habits and structures of modern ants products of recent evolution? From Dr. Wheeler's researches we gather these facts:

1. Of the amber genera, over 55 per cent. are still living; that is to say, 24 genera, of which four are at present cosmopolitan; four universal in the tropics, but invading semi-tropical or temperate regions with some of their species; four essentially paleotropical; five belonging to an Indomalayan and Australian series; six circumpolar; and one (*Erebomyrma*) known to-day by two species, one in Texas, the other in Peru.

2. The extinct genera are mostly allied to paleotropical forms. There is, however, little affinity with the African fauna.

3. It is by no means certain that the amber fauna all belongs strictly to the same time or general locality; yet ten cases are recorded in which two species of ants exist in the same block of amber, proving their strict contemporaneity.

4. Since the amber, "the family has not only failed to exhibit any considerable taxonomic or ethological progress, but has instead suffered a great decline in the number of species and therefore also in the variety of its instincts, at least in Europe." Already, in the Lower Oligocene, the subfamilies and modern genera were established; even some of the species were almost identical with those of to-day. *Formica flori* of amber is almost exactly the modern *F. fusca*; other species of *Formica* represent different subdivisions of the genus, quite as we have them to-day, though there is no representative of *F. sanguinea*. Other amber ants show similar resemblances. Not only was polymorphism fully established, but the larval and pupal stages show such peculiarities as we see to-day; thus the larvae of *Prenolepis* had already lost the cocoon-spinning instinct. The amber *Iridomyrmex* pupae were likewise naked, just as they are now. Specimens of *Lasius* carry gamasid mites, showing that these arachnids had already developed their specialized myrmecophilous characters. So also, aphids were kept by ants in those days.

5. Perhaps it would hardly be going too far to say that if the ants of to-day were likewise preserved in amber, and were submitted to a future entomologist along with those of the

Oligocene, without any information concerning their relative ages, he would hesitate to declare which was the older. At the same time, the amber ants do show some relatively primitive features, and *Prionomyrmex*, from the amber, is absolutely the most primitive of known ants. The nearest living relative of *Prionomyrmex* is the Australian *Myrmecia*. It must also be noted that the amber ants have not so far shown any marked soldier types, like that of *Pheidole*.

Some years ago I had occasion to study the bees of Baltic amber and found all the genera to be extinct, although the fossorial wasps from the same material, so far as seen, were strictly of modern genera. It is certainly true that different genera and families of insects differ greatly in their antiquity, and some of those which we might naturally suppose to be relatively recent are in fact very old. Such studies as this of Dr. Wheeler's supply a firm foundation of facts to take the place of guesses, and are of inestimable value to students of evolution.

The Examination of Hydrocarbon Oils and of the Saponifiable Fats and Waxes. By DR. D. HOLDE. Translated by EDWARD MUELLER, from the fourth German edition. John Wiley and Son, Inc. 1915. Pp. 483.

To present in the limited space of this book even a brief description, and standard methods of examination of the great variety of petroleum products and fats, demands a comprehensive knowledge and critical judgment. In the last edition of Dr. Holde's work this object has been well accomplished.

Petroleum and its products, the most voluminous part of the subject, occupy the larger space, yet the saponifiable fats and their products are quite comprehensively included.

In its general plan the book presents brief descriptions of properties and composition, general reactions, behavior towards reagents and standard quantitative physical and chemical methods of examination. There is a great condensation of subject-matter by means of the

97 tables that are interspersed throughout the book, and that summarize much valuable data in connection with the subject in hand.

Products recently brought into commercial use are described with methods of control. The physical examination of the hydrocarbon oils and their derivatives includes specific heat, heat of vaporization, viscosity, calorific power, coefficient of expansion and optical properties. Rotary power of mineral oils receives attention, more especially in European oils where it is apparently more general than in American crude oils, or their products. The recently proposed formolite reaction (formic aldehyde and concentrated sulphuric acid) on mineral oils is described, and some other recently proposed methods. Large space is properly devoted to lubrication, lubricants and greases, asphalts and tars. With the marvelous expansion in the use of motor power, the several recent methods for increased output of gasoline from inferior oils and the general replacement of kerosene for lighting, it appears that gasoline and lubricants will soon be the principal products refined from petroleum. Much serviceable information is presented concerning non-drying oils and solid fats, vegetable semi-drying oils, and drying oils, animal oils and oils from marine sources. The chapter devoted to technical products derived from fats and oils, blown oils, soaps, soap powder, turpentine wood oils, boiled oils, resins and allied products both in description and methods will be found useful.

Certain looseness in statement appears here and there. Caustic soda is of equal necessity with sulphuric acid in refining to remove sulphonic acids and particles of sludge that permeate the oil after the acid treatment. Fuller's earth is used only after acid treatment to remove color. The two general types of petroleum suggested are not inclusive. The writer has a barrel of Russian crude oil that distills to less than one per cent. below 850° at. pres. California, Wyoming, much Kansas, and southern crudes do not fall within this classification. Mercaptans are not contained in American crudes so far as known. On page 63 it is mentioned that the method of Carius

is not suited for the determination of sulphur in kerosene, since even a poor oil must not contain more than a few tenths of one per cent. of sulphur and only a small amount of the oil can be used. Probably by tenths was intended a few hundredths of one per cent. Of course the simplest way for sulphur in kerosene is the lamp method that has been used by the Standard Oil Company for many years. But sulphur to thousandths of one per cent. in any crude petroleum or in any of its products, except perhaps the most volatile gasoline, may be expeditiously determined by combustion in oxygen and titration. This standard method in use for years is not mentioned.

Neither Texas, Ohio, nor other American crudes, except those in California, contain any large proportion of nitrogen compounds, and these compounds so far as examined are not of the pyridine series but, including Baku-crude, they are derivatives of the hydrochinoxalines.

However, those minor inaccuracies do not detract from the usefulness that this book offers to all workers in these broad fields.

CHARLES F. MABERY

THE ADOPTION OF THE MISSOURI SYSTEM OF GRADING AT GOUCHER COLLEGE

At Goucher College the faculty has recently adopted the "Missouri System" of grading. It may be of interest to some who are contemplating the introduction of this system, or to others interested in the theory and practise of grading, to learn a few of the details of this proposed application of the system.

Four passing grades and two grades below passing are defined. Grade C is to be assigned to approximately the middle 50 per cent. of each class. Grades A and B together are assigned to those above C, grade A being that of approximately the uppermost 3 per cent. and B that of about the other 23 per cent. In the opposite direction, grade D is to be assigned, in required courses, to approximately the 15 per cent., and in other courses to about the 22 per cent., just below C. Grade E is to indicate incomplete work or unsatisfactory work that can easily be made up, such as is customarily

marked "conditioned." Grade F denotes failure to receive any credit for the course. Grades E and F together are to be assigned, according to the discretion of the instructor, to approximately the lowest 10 per cent. in required courses, and to the lowest 3 per cent. in other courses.

These percentages are summarized as follows:

	Passing Grades				Not Passing	
	A	B	C	D	E and F	
In required courses	3	22	50	15	10	
In other courses	3	22	50	22	3	

It will be seen that grade A is intended to mark work of unusually good quality which it seemed desirable, in the absence of any other system of "honors" in the college, to distinguish from that accomplished among so large a group as the upper fourth. The difference in the percentages of conditioned and failed (E and F) in required and not-required courses, is intended partly as a check upon entrance; it also takes into account the fact that under the usual conditions of admission to colleges, there should be a considerable elimination of the poorest students during the first years of the college course, when the proportion of required courses is high. Moreover, this arrangement recognizes that students are guided somewhat in their choice of elections by the advice of instructors and by their tendency to elect work in subjects which experience has shown them fitted to continue.

Theoretically the elimination of the poorest students in the required work early in the curriculum would affect slightly the sizes of all the remaining groups in the advanced or elective courses, but in practise this effect would probably not extend beyond the lowest passing grade; hence grade D is enlarged in these courses, while the middle and higher grades are not altered. Whether this will result in justice on the whole, can be determined only after experience with the system.

The size of the upper grades A and B is not increased in the most advanced or major courses, for the simple reason that to do so would in effect be applying the standard of

the elementary course to the work of the advanced course. When expectation or requirement concerning quality of work advances in correspondence with the advanced character of the courses, justice is most nearly assured by assigning approximately the same percentages of grades A, B, C in all courses.

The system as adopted emphasizes also the idea that the proposed percentages may not be precisely observed in any single class in a single year, especially among the smaller classes. But it is expected that the deficiencies in the assignments of particular grades of one year, will be balanced by the excesses of another year, so that there will be no constant tendency on the part of any instructor's grades to deviate widely from the percentages agreed upon. In very small classes the grades of a single year may deviate more widely from the ideal than those of the larger classes, but the combined reports of several years are expected to show essential approximation to the definitions.

GOUCHER COLLEGE

SPECIAL ARTICLES

A SAFE PORTABLE LAMP BATTERY

THE use for class work in physiological laboratories of zinc and ammonium chloride, or other forms of cells, is inconvenient and involves constant renewal. To supply large classes with dry batteries becomes an item of considerable expense. When the 110-volt direct current is available "lamp batteries" (or, properly speaking, lamp resistances) are more convenient, and cheaper to use; and if they are permanently installed under the work bench where the student can not alter the connections nor easily short circuit them, they are safe enough.

For many purposes, however, it is more convenient to have the lamps mounted on a piece of board six or eight inches square, so that the battery can be carried anywhere about the laboratory and connected with any socket by means of a cord and plug. The great disadvantage of such a portable battery is that with inexperienced students it may easily re-

sult in a serious blow-out. Thus with the ordinary arrangement of the lamps, as shown in Fig. 1, if *B* is the live wire and *A* is the grounded wire of the city lines (and one is usually grounded), no harm results if *B* happens to come in contact with a gas or water pipe. But if *A* is the live wire, and one happens (as there is an even chance of doing) to have pushed the plug into the socket so that the lamp *O* is nearest to the grounded line, then the whole pressure of the city system bears upon any chance contact of *F* with any metal object leading to ground.

FIG. 1

To avoid this danger the form of battery shown in Fig. 2 has proved convenient. To give the same current the lamps *O* and *O'* in Fig. 2 must be twice the size (twice the current consumption and illuminating power, or in other words half the resistance) of *O* in

FIG. 2

Fig. 1. As both sides of the battery are then the same, it does not matter whether *A* or *B* is the live wire, nor which way the plug is put into the socket. If *E* or *F* happens to touch a grounded object, the lamp on that side merely

brightens (they are usually barely luminous), while that on the other side becomes entirely dark. For most physiological purposes a suffi-

FIG. 3

cient current is obtained if *C* and *C'* are 80-watt carbon filament lamps and *D* is a 50-watt

FIG. 4

lamp. For some physiological induction coils (*e. g.*, the Harvard coil) it is necessary, however, to use larger lamps (120 watts) in *C* and *C'*. If still more current is wanted two or more sockets can be screwed to the board on each side, connected in parallel and filled with lamps until the needed current is obtained. Fig. 3 shows the arrangement of the sockets on the board.

In Fig. 4 is shown a convenient method of wiring the entire student laboratory for recording time. The figure shows at the left the lamp battery and the clock. The latter may be placed either in series with the signal magnets or so as to short-circuit the current, as it is in the diagram. The signal magnets must all be arranged on the line in series, each with a short-circuiting key to be closed when the time record at that place is to be discontinued

or the signal magnet disconnected. With this arrangement it is not easy for one careless student to upset the entire system, and he is easily located if he does. One lamp battery operates effectively a large number of signal magnets in series.

When, as in work with the graphic method, it is desired to have an automatic record on the smoked paper of the instant at which some nerve was stimulated, the arrangement shown at the right in Fig. 4 is convenient. It consists merely of another lamp battery, induction coil and a double knife-edge switch. One blade of the switch is connected as a making and breaking key in the coil circuit, and the other as a short-circuiting key in the time circuit. Thus the interval of stimulation when the key is closed is indicated on the graphic record by the cessation of the movements of the signal magnet, and the time record recommences the

instant the stimulation is ended by the re-opening of the key. YANDELL HENDERSON

YALE MEDICAL SCHOOL

A SIMPLE DEVICE FOR DEMONSTRATING THE TEMPERED SCALE

THE diatonic scale, consisting of a succession of eight tones and containing three intervals known as "major second intervals," two known as "minor second intervals" and two "half-tones," is not adapted to musical instruments of "fixed pitch" (*e. g.*, the piano, harp, etc.) for the reason that it does not without a multiplicity of keys (strings) allow of transposition or change of keys.

For fixed-pitch instruments, therefore, the scale is modified in the following manner. First, an additional tone is inserted in each of the larger intervals (major and minor seconds)

of the scale—thus breaking the octave into twelve instead of seven intervals, and second, the pitches of the various tones are so altered as to make the interval between any two successive tones the same. This scale is known as the scale of "equal temperament" or briefly, the tempered scale.

The "interval" between two tones, as the term is here used, is the ratio of the pitch of the higher tone to that of the lower. It follows that on the tempered scale this ratio is the same for any two adjacent tones. The numerical value of this interval is 1.05946, since the sum of twelve such intervals is 2, the numerical value of the octave interval.

These considerations coupled with the fundamental law of string vibrations, to the effect

which $Oc/OC = OC/Od = Od/OD = \text{etc.}$, the value of this ratio being 1.05946 by construction.

If this diagram is drawn on the top of a sonometer, or a table-top across which a string is stretched, and bridges are placed under the string opposite O and c , it forms a complete finger board for running the major, minor and chromatic scales.

The device lends itself to the demonstration of the following relations:

(1) Comparison of the major and minor scales. (2) Comparison of the major and minor chords. (3) To show that on the tempered scale any note may be taken as key note, and all scales are equally good. For this purpose choose any point as starting point, call-

FIG. 1

that, for a string of given weight and tension, the frequency of a vibrating segment is inversely proportional to its length, suggest a simple method of finding those string lengths which will give the successive tones of the tempered scale.

Draw two intersecting straight lines including any convenient angle (see accompanying diagram). From the point of intersection lay off on one line any convenient length $Oc = L$, on the other a length $OC = L \div 1.05946$. Join the points Oc by a straight line.

Locate the corresponding points B and $c\sharp$ and join by a dotted straight line. Now draw the series Cd , dD , De , etc., and the dotted series, parallel to $Bc\sharp$ and cO . By this means the points $c\sharp$, d , $d\sharp$, e , etc., are determined at which a string of length L ($=Oc$) must be stopped to give the successive tones of the tempered (chromatic) scale. This will be evident from the construction of the figure in

ing it point 1. Number the points from point 1 upward. Sound in succession the tones given by the string when stopped at points 1, 3, 5, 6, 8, 10, 12 and 13. (4) Comparison of just and tempered scales. Lay off from O on Oc lengths equal to $8/9$, $4/5$, $3/4$, $2/3$, $3/5$ and $8/15$ of L . The points so determined are those at which the string should be stopped to give the tones of the just scale. A glance at the board will now show to what extent each interval of the tempered scale is falsified.

L. B. SPINNEY

IOWA STATE COLLEGE

THREE STRAWBERRY FUNGI WHICH CAUSE FRUIT ROTS

In my investigation of strawberry troubles in Louisiana last year,¹ and later in a study of market berries in this state, I frequently found upon spotted berries the fungi described be-

¹ SCIENCE, N. S., 39: 949, 1914.

low. The diseases were present in so large a percentage of the market berries as to make it apparent that they are real economic factors. In a recent trip to the Louisiana strawberry fields (April, 1915), I found the same fungi present upon berries still in the fields. The fungi have been isolated in pure culture and inoculations made. It seems desirable therefore to call attention to them at this time. A complete presentation of their study will be made later.

Strawberry Fruit Rot Due to Patellina Sp.

This rot begins either on green or ripe berries as a microscopic spot which enlarges slowly in green berries and more rapidly in ripe ones. In ripe berries the spot becomes sunken, the area tan colored. The margin is quite definite. The surface is soon studded thickly with sporodochia which vary from globular to patelliform to saucer-shaped, usually with a distinct, often wrinkled sterile margin. In color they vary from hyaline to tan, or when resting on the ripe berry they may take on completely the color of the berry.

The core of the diseased spot is completely occupied by the mycelium, rendering it of spongy tenacious texture. The host cells along a narrow line separating the diseased from the normal area are softened and separated from each other, evidently by enzyme action. It is therefore possible to lift out in its entirety the diseased tissue. The spot in a ripe berry increases in size sufficiently fast to involve the whole of a large berry in about four days. The fungus has been isolated and positive inoculations have been made. It clearly belongs to the genus *Patellina* and appears to be as yet undescribed.

Strawberry Fruit Rot Due to Sphaeronemella Sp.

This rot occurs with or separate from the one above described. It differs distinctly in character of spot and is much less rapid in its effects. The spot is not definitely bounded nor is there such evidence of enzyme action as described above. The affected berry soon becomes completely covered with the *pycnidia*, which

are tan-colored to black, distinctly rostrate and are of such peculiar gelatinous texture that berries affected with this disease can be distinguished by feeling of them.

The causal fungus has been isolated and positive inoculations have been made. It is a *Sphaeronemella* apparently quite distinct from *Zythia fragariae* Laib. and seems to be undescribed.

Each of the above fungi has been found repeatedly on market berries and they are clearly present in sufficient frequency to render them of considerable economic significance.

Strawberry Black Rot Due to Sphaeropsis

LAST year both in Louisiana and in the market here, I frequently found berries which showed a very peculiar blackening or a bronzed appearance. Such berries rotted down dry and eventually shrivelled. Examination showed the presence of abundant dark coarse mycelium similar to that of *Sphaeropsis malorum* and of pycnidia and spores also, as yet indistinguishable from that fungus. This disease was not nearly so abundant as the two above described and is not of much economic significance.

SOCIETIES AND ACADEMIES

THE BOTANICAL SOCIETY OF WASHINGTON

THE 105th regular meeting of the Botanical Society of Washington was held in the Assembly Hall of the Cosmos Club, at 8 P.M., Tuesday, May 4, 1915. Thirty-three members and four guests were present. Dr. George R. Lyman was elected to membership. Dr. Camillo Schneider, general secretary of the Dendrologischen Gesellschaft of Austria-Hungary, was present as a guest of the society. The scientific program was as follows:

The Botany of Western Yunna (China): DR. CAMILLO SCHNEIDER.

Dr. Schneider has just returned from a year's journey in the high mountains of western Yunna. He has carried on in the region of the upper Yangtze investigations in botany, zoology and ethnology. He obtained a great number of colored photographs taken from nature (Lumiere, autochromes) of which he exhibited 25 with the lan-

tern. These showed most interesting plant types of the high mountains near Li Chiang at an elevation of 10,000 to 17,000 feet. Especially striking was a new *Primula*, first discovered a few years ago, with a spiked inflorescence which more resembles an orchid than a *Primula*. It has been named *P. Littoniana*. The buds are of a dark purple, while the open flowers are colored. A very peculiar plant of biological interest is a new *Saussurea*, which inhabits limestone boulders at about 17,000 feet and has the flowers hidden among the leaves, which are densely hairy and protect them from snow and frost. The virgin forest of the Li Chiang zone consists of *Pinus Massoniana*, various *Piceas*, *Abies Delavaya*, *Tsuga Yunnanensis*, evergreen oaks, many *Rhododendrons* and numerous other shrubs and herbs. The cryptogamic flora is also very rich. Dr. Schneider has collected over 3,000 different species of phanerogams and ferns.

The Genus Endothia: DR. N. E. STEVENS.

To be published in full elsewhere.

Endothia Pigments: DR. LON A. HAWKINS.

To be published in full elsewhere.

Identification of the Teonanacatl, or "Sacred Mushroom" of the Aztecs, with the Narcotic Cactus, Lophophora Williamsii, and an Account of its Ceremonial Use in Ancient and Modern Times: MR. W. E. SAFFORD.

The early Spanish writers describe certain feasts of the Aztecs in which a narcotic called by them *teonanacatl*, or "sacred mushroom" was used as an intoxicant. Bernardino Sahagun, writing before 1569, states that it was the Chichimeca Indians of the north who first discovered the properties and made use of these "evil mushrooms which intoxicate like wine." Hernandez distinguishes them from other mushrooms (*nanacome*, plural of *nanacatl*) which are used as food, by the distinguishing adjective *teyhwinli*, inebriating, "*quoniam inebrare solent*." The belief survives that the drug thus used was a mushroom; according to Rémi Siméon, the *teonanacatl* is "une espèce de petit champignon qui a mauvais goût, enivre et cause des hallucinations."¹ Investigations of the author have proved that the drug in question is not a fungus but a small fleshy spineless cactus endemic on both sides of the Rio Grande in the vicinity of Laredo, Texas, and in the state of Coahuila, ranging southward to the states of Zacatecas, San Luis Potosí, and Querétaro, a region inhabited in ancient times by the tribes

¹ "Diet. de la langue Nahuatl," p. 436, 1885.

called Chichimecas. The drug is prepared in two principal forms: (1) discoid, in which the head of the plant is cut off transversely, and when dried bears a close resemblance to a mushroom; (2) in longitudinal pieces or irregular fragments, in which the entire plant, including the tap root, is sliced longitudinally into strips, like a radish or parsnip, bearing no resemblance whatever to a mushroom, and designated by early writers as *peyoti*, and also as *raie diabolica*, or "devil's root."

The first to call attention to the ceremonial or religious use of this drug by the Indians of today was Mr. James Mooney, of the Bureau of American Ethnology, in a paper read before the Anthropological Society of Washington, November 3, 1891. Since the time of Mr. Mooney's observations the use of the drug has spread widely among the Indians of the United States, by whom it is commonly called "mescal button" or "peyote."

Efforts have been made to prevent the Indians from using it, chiefly because it is believed by some of those interested in the Christianizing of the Indians that it has a tendency to make them revert to their primitive condition and to their heathen beliefs. Action was taken in the courts to prosecute a certain Indian for furnishing this drug to the Indians of the Menominee Reservation of Wisconsin on March 15, 1914. It developed that the drug was received by parcel post from the vicinity of Laredo, Texas. In a paper before the Lake Mohonk Conference in October, 1914, affidavits of certain Indians of the Omaha and Winnebago tribes of the Nebraska reservation were read. The evidence showed that there is a religious organization among the Indians called the "Sacred Peyote Society," the ceremonial meetings of which are remarkably like those of the ancient Mexicans in which the "sacred mushroom" was eaten; and the physiological effects, as described by those partaking of the drug, were identical with those attributed by the early writers to the *teonanacatl*. The chemical properties of the drug have been studied in Germany and the United States, especially by Lewin, of Berlin, Heffter, of Leipzig, and the late Ervin E. Ewell, of the Bureau of Chemistry, U. S. Department of Agriculture; and the physiological effects by Drs. D. W. Prentiss and Francis P. Morgan, of Washington, D. C.; but it is not possible to give the detailed results of these investigations in the scope of the present paper.

As far as the author knows, this is the first

time the identity of the "sacred mushroom" or "flesh of the gods" with the narcotic cactus known botanically as *Lophophora Williamsii* has been pointed out. That the drug was mistaken for a mushroom by the Aztecs and early Spaniards is not surprising when one bears in mind that the potato (*Solanum tuberosum*) on its introduction into Europe was popularly regarded as a kind of truffle, a fact which is recorded by its German name *Kartoffel*, or *Tartuffel*.

PERLEY SPAULDING,
Corresponding Secretary

THE BIOLOGICAL SOCIETY OF WASHINGTON

THE 542d meeting of the society was held in the Assembly Hall of the Cosmos Club, Saturday, May 15, 1915, called to order at 8 p.m. by President Bartsch, with 43 persons present.

On recommendation of the Council, Francis N. Balch, Boston, Mass., and Ernest P. Walker, Wrangell, Alaska, were elected to active membership.

Under heading exhibition of specimens, Dr. L. O. Howard showed lantern slides from photographs of the moth, *Ceratonia amyntor*, bringing out its protective coloration while at rest on bark.

The first paper of the regular program was by C. H. T. Townsend, "Two Years' Investigation in Peru of Verruga and its Insect Transmission." Dr. Townsend said:

The four stages of verruga are defined as incubative, fever, quiescent and eruptive. The most important symptom of the fever stage is the presence of bacilliform bodies (*Bartonella bacilliformis* Strong et al.) in the erythrocytes. The histology of the eruptive papules is not yet sufficiently defined for positive diagnosis in the absence of the clinical history, but its chief feature is a marked proliferation of angioblasts.

Verruga Canyon is the best known and probably one of the strongest endemic foci of the disease. Extended investigations were carried on there both day and night at all seasons of the year. The result was an ecological demonstration of *Phlebotomus verrucorum* Townsend as the vector of the disease. This demonstration is built on the unique etiological conditions already known. Verruga can be acquired only by direct inoculation into the blood, is only contracted at night, is confined to very restricted areas within which it is almost universally contracted at any time of year by nonimmunes who remain from seven to ten consecutive nights. These conditions necessitate a blood-seeking vector which is abundant, active only

at night but throughout the year, and whose distribution is coterminous with the infected areas. The above *Phlebotomus* is the only bloodsucker which meets these requirements.

Clinical verification of the vector was obtained from the history of numerous cases of verruga observed by Dr. Townsend. Transmissibility demonstration in laboratory animals lacked completeness only by reason of the impossibility of positively diagnosing verruga eruptive tissue, papules having been produced in the animals by injections of the crushed *Phlebotomus*.

A biting experiment in man was carried through, resulting in what appeared to be a light infection. This was the case of McGuire, who exhibited all the symptoms but with a paucity of the bacilliform bodies in the erythrocytes. Papules appeared springingly after the subject had been discharged. Dr. Townsend's assistant, Mr. Nicholson, accidentally received many *Phlebotomus* bites, thereby furnishing a clean experiment with two checks. The checks were Dr. Townsend and his assistant, Mr. Rust, both of whom were subjected to exactly the same conditions as Mr. Nicholson except that they did not receive the bites. They did not contract the disease, while Mr. Nicholson showed a well-marked case with both the bacilliform bodies in the erythrocytes and the characteristic eruption.

Lizards were suggested as a possible reservoir of verruga, from the fact that they were the only vertebrates aside from man, domestic or wild, at Verrugas Canyon, whose blood showed bacilliform bodies. The lizards inhabit the numerous loose rock walls which everywhere in the Andean region take the place of fences, and these are the favorite diurnal hiding places of the *Phlebotomus* swarms. Injection of the lizard blood into guinea-pigs resulted in similar bodies in the erythrocytes of the injected animal.

The unity of verruga was insisted on, in opposition to the thesis of Dr. R. P. Strong and his associates. The entire Peruvian medical fraternity concur in this view. The facts given in support of it appear to be irreconcilable with the opposite view.

Prophylactic measures were outlined; and the remarkably perfect climatic conditions of the verruga zones, unequaled for malarial, were dwelt on.

The paper will be published in full in the *American Journal of Tropical Diseases and Preventive Medicine*.

Dr. Townsend's paper was illustrated by lantern

slides made from photographs of *Bartonia bacilliformis*, of clinical cases, of the micro-pathology, of the *Phlebotomus*, and of Verrugas Canyon, etc. It was discussed by Admiral G. W. Baird and medical inspector H. E. Ames.

The second paper of the regular program was by W. Dwight Pierce, "The Uses of Weevils and Weevil Products in Food and Medicine." Mr. Pierce described in particular the trehala manna of Syria which is the cocoon of the large weevil known as *Larinus nidiolus*. These cocoons are used by the natives as a food similar to tapioca and are also commonly sold in drug stores for use in making a decoction said to be efficacious against bronchial catarrh. The cocoons are made by an abdominal excretion of the larva and contain a large percentage of sugar known as trehalose as well as a carbohydrate, a little gum, and a small amount of inorganic mineral matter.

Specimens of the trehala manna and of the weevil were exhibited.

The third communication was by L. O. Howard, "Some Observations on Mosquitoes and House Flies." Dr. Howard spoke of the work which is being done in New Jersey against mosquitoes, describing the organization of county inspectors which was effected at Atlantic City in February at an "antimosquito convention." He showed a series of lantern slides illustrating the very effective work done by the Essex County Commission in the vicinity of Newark, N. J. He then spoke of work done by Mr. Hutchinson of the Bureau of Entomology in regard to trapping the maggots of the house fly, illustrating his remarks with lantern slides showing a large out-door maggot trap in use during the summer of 1914 under Mr. Hutchinson's direction at College Park, Md. The illustrations in question appear in U. S. Department of Agriculture Bulletin No. 200.

The last communication was by A. L. Quaintance, "Remarks on Some Little-known Insect Depredators."

Mr. Quaintance called attention to certain species of insects which have but recently come into prominence as of economic importance and to other species which, although long known to entomologists as occasional pests, have recently attracted attention in view of local outbreaks. A species of Jasside, *Typhlocyba obliqua*, is at the present time seriously destructive to apples in portions of the Ozark mountain region and in Kansas. These insects occurred in countless numbers in some orchards, infesting the lower surface of the leaves, causing the foliage to drop with subse-

quent injury to the fruit crop and the trees. A Tineid insect of the genus *Marmara* was reported to have caused a good deal of injury to certain apple orchards in Albemarle County, Virginia. The caterpillar makes long, serpentine mines under the skin of the apple, resulting in blemishes. The keeping quality of the fruit is also lessened. The common walking stick, *Diapheromera femorata*, while often the cause of more or less local defoliation in forests, occasionally becomes a serious pest in orchards, especially in orchards adjacent to woodlands. These walking sticks have recently been complained of on account of important injuries to apple and peach orchards in Virginia and West Virginia. *Rhabdopterus pisces*, a Chrysomelid beetle, has recently been discovered as damaging cranberries. The insect is a near relative of the grape root worm, *Fidia viticida*, and the larvae work on the roots of cranberry, feeding principally on the fibrous roots, but also stripping the bark from the older roots. Investigations of the insect by Mr. H. B. Scammell indicate that it is restricted in cranberry bogs to the higher and sandier soils. *Nezara hilaris*, one of the stink bugs, and long known to feed on vegetation of various sorts, has recently become very abundant and destructive to peaches in the Marblehead district in northern Ohio. These plant bugs in feeding insert their beaks in the developing fruit, causing the peaches to become knotty and misshapen as they grow, and many of which fall from the trees. *Parandra brunnea*, better known as the chestnut telephone borer, following investigations by Mr. Snyder, has been determined by Mr. Fred. E. Brooks to be very generally present in the heartwood of old apple trees and as a result of its work the trees are often so weakened that they are easily broken or blown over by winds. Various species of Cecidomyiidae are known to be serious crop pests, as the sorghum midge, the pear midge, etc. A new midge pest, *Contarina johnsoni*, has during recent years come into prominence on account of its injuries to grapes in the Chautauqua and Erie grape belts. The adults oviposit in the blossom buds which may contain from 10-70 maggots, though the average number is much less. Many blossoms are thus destroyed, resulting in very ragged and imperfect bunches of grapes.

This paper was illustrated by lantern slides showing the insects and their work from photographs prepared mostly by Mr. J. H. Paine.

At 10.15 the society adjourned until October.

M. W. LYON, JR.,
Recording Secretary.

¹MS. intended for publication and books, etc., intended for review should be sent to Professor J. McKen Cattell, Garrison-Hudson, N. Y.

AUGUST WEISMANN, a foreign member of this society, was born at Frankfort on the Main, January 17, 1834, and died at Freiburg in Breisgau, November 6, 1914. He early showed the traits of a naturalist and in one of his books speaks of the excitement he felt as a boy in catching butterflies. He attended the University of Göttingen, where he studied chemistry and medicine, coming especially under the instruction of the distinguished anatomist Henle, and receiving the degree of M.D. in 1856. After spending three years at Rostock as an assistant he began the practice of medicine at Frankfort and during this time he visited Vienna in 1858, Italy in 1859 and Paris in 1860. From 1861 to 1862 he was private physician to Archduke Stephan of Austria at Schamburg Palace. He then studied zoology at Giessen under the renowned zoologist Leuckart and became privat-docent in zoology at the University of Freiburg in 1863, where he spent the remainder of his life. In 1866 he was appointed professor extraordinarius and a few years later became professor ordinarius, which position he continued to hold until a few years before his death, when he was made professor emeritus.

In person he was a man of striking appearance, being about six feet tall and well proportioned and having a fine head and face and an earnest but kind expression of the eyes. From 1864 to 1874 and again from 1884 on he suffered from an eye trouble which interfered greatly with his

¹ Read before the American Philosophical Society, January 1, 1915.

microscopical work and turned his attention to theoretical questions. One of his former students and assistants, Professor Alexander Petrunkevitch,² to whom I am indebted for much valuable information concerning his personality, says that although he was usually quiet in manner, he invariably became nervous and unhappy in the presence of moving objects, which painfully affected his eyes.

A short autobiography published in *Lamp* in 1903 gives a glimpse of his family life:

During the ten years (1864-74) of enforced inactivity and rest occurred my marriage to Fräulein Marie Gruber, who became the mother of my children and was my true companion for twenty years until her death. Of her now I think only with love and gratitude. She was the one who more than any one else helped me through the gloom of this period. She read much to me at this time, for she read aloud excellently, and she not only took an interest in my theoretical and experimental work, but she also gave practical assistance in it.³

His great work on the "Natural History of the Daphnoidea" (1876-79) is dedicated to "My father-in-law, Adolph Gruber, in thankful memory of the beautiful hours of leisure spent on the shores of Bodensee." His colleague, the anatomist Wiedersheim, married another daughter of Gruber who was a Genoese banker. After the death of his first wife Weismann married again when about sixty years old, but not happily. One of his daughters married the zoologist W. N. Parker, who translated into English his best-known work "The Germ Plasm." A son was trained as a professional violinist.

Weismann, like so many other naturalists, was of an artistic disposition. He loved nature, art and music and he was an

accomplished pianist. During the periods when he suffered much from his eye trouble he says that he "found solace in playing a good deal of music." He was an enthusiastic admirer of Beethoven, but could not appreciate Wagner. His artistic temperament is further shown in many of his essays, which for beauty of expression are rarely surpassed in scientific literature.

He was an excellent speaker, being simple and earnest in manner and never indulging in jokes. His lectures on evolution, which were delivered regularly for almost forty years, were famous and always attracted great audiences. As a teacher of advanced students he was stimulating and helpful, a kind critic and an attentive listener.

He took no active part in politics, but, like many German professors, was a member of the "National Liberal" party. In philosophy he held tenaciously to a mechanistic conception of nature, but he believed that extreme mechanism was consistent with extreme teleology; indeed, he held that

The most complete mechanism conceivable is likewise the most complete teleology conceivable. With this conception vanish all apprehensions that the new views of evolution would cause man to lose the best that he possesses—morality and purely human culture.

In his philosophy as in his scientific controversies he was extremely tolerant. He was interested in the promotion of knowledge, but was not aggressive nor offensive in manner.

Inasmuch as his life was so largely given to the extension and support of the Darwinian theory, it is interesting to hear from himself how that theory first came to his attention. After remarking, "I never heard evolution referred to in my student days," he describes the influence on himself of Darwin's book in these words:

I myself was at the time in the stage of metamorphosis from a physician to a zoologist, and as

² I am also indebted to Professor H. H. Wilder, of Smith College, and to Professor J. S. Kingsley, of the University of Illinois, for information regarding the family life and personality of Weismann.

³ Quoted from Locy's "Biology and its Makers," p. 401.

far as philosophical views of nature were concerned I was a blank sheet of paper, a *tabula rasa*. I read the book ["Origin of Species"] first in 1861 at a single sitting (*sic*) and with ever-growing enthusiasm. When I had finished I stood firm on the basis of the evolution theory, and I have never seen reason to forsake it.

With just pride he mentions the fact that he was one of the first scientific men in Germany to defend publicly Darwin's theory; Fritz Müller was the first to publish a work in favor of that theory ("Für Darwin," 1864), Haeckel was the second ("Generelle Morphologie," 1866) and Weismann was the third, his inaugural address at Freiburg on the "Justification of the Darwinian Theory" ("Ueber die Berechtigung der Darwin'schen Theorie") being published in 1868.

Thereafter his contributions to the Darwinian theory were numerous and important. They appeared from 1872 to 1902 as a series of books and contributions. Five of these earlier contributions were translated into English by R. Meldola and were published as two large volumes in 1882, with an introduction by Charles Darwin. Subsequent studies on evolution were so intimately associated with his theories of heredity that they can best be considered under that topic.

Weismann's contributions to biological theory were so extensive and important that they overshadow to a great extent his observational and experimental work, and yet the latter was by no means small or unimportant. Among these observational and experimental studies must be mentioned especially his extensive works on "The Development of Diptera" (1865), "Natural History of the Daphnoidea" (1876-79), "Origin of the Sex Cells of the Hydromedusae" (1883), "Seasonal Dimorphism of Butterflies" (1875), "Origin of Markings of Caterpillars" (1876) and

"Transformation of the Mexican Axolotl into *Amblystoma*."

Some of his earlier work was done without assistance, but in all of his later observational and experimental studies he had the assistance of his wife or other helpers. Much of his work was done in collaboration with some of his students or assistants. His method of work was to a large extent forced upon him by his eye affliction. After 1864 all reading had to be done for him, at first by his wife and after her death by a secretary. Experimental work was done under his supervision by his assistant and janitor. All microscopic work was done by his pupils, to whom he suggested topics and whose work he supervised daily. These theses were always in direct relation to his theories and to that phase of them which interested him most at the moment.

But valuable as much of his observational and experimental work was, there is no doubt that he will be remembered chiefly for his theories of heredity. His earliest writings on this subject date from the year 1883 and his latest were published but a few years before his death. His "Essays upon Heredity and Kindred Biological Topics" were translated into English and published in two volumes in 1889 and 1892. Probably his most important work on this subject is his book entitled "The Germ-Plasm, A Theory of Heredity" which was published in English in 1893. Subsequent works on heredity are "On Germinal Selection" (1896) and "Vorträge über Descendenztheorie" (1902). This last-named work, which was published in English under the title "The Evolution Theory" (1904), consists of a summary and an expansion of many of his previous writings on the subjects of evolution and heredity; indeed, as he says in the preface of this book, it is "a mirror of the course of my own intellectual evolution."

Without attempting to analyze these different books, which would require more time and space than is here available, we may proceed at once to a summary of his more important contributions to the theories of evolution and heredity.

All his theories, of both heredity and evolution, center in what he called the "germ-plasm," that particular part of the germ-cells which serves to carry over from generation to generation the inheritance factors. This germ-plasm was held by Weismann to be absolutely *continuous* from the present generation back to the earliest generations of living things; it was absolutely *distinct* from the somatoplasm of the body and the latter could never become germ-plasm; it was almost perfectly *stable*, undergoing practically no changes except such as came from the mixing of different kinds of germ-plasm (*amphimixis*) in sexual reproduction.

These views as to the nature of the germ-plasm underwent some modification as the result of criticism. Weismann was forced to admit that the distinctness and stability of the germ-plasm were not absolute, but in spite of all criticism he was able to maintain that the germ-plasm was relatively very distinct from other plasmas and very stable in organization, and this is now admitted by all persons acquainted with the subject.

His views as to the separateness of somatoplasm and germ-plasm, of body cells and germ cells, and the mortality of the former and potential immortality of the latter, led him to regard organisms in which this distinction does not exist (many protozoa and protophyta) as potentially immortal. With a keenness of insight which was not appreciated at the time, but which has been confirmed by recent work, he reasoned that "conjugation like food and oxygen may be conditions of life, but immortality does not rest on the magic of conjugation any more

than on food or oxygen." Again he anticipated the most recent opinions when he held that death is not a necessary correlative of life, but rather the result of higher differentiation. In short, as Minot said, "Death is the price we pay for our differentiation." On the other hand, his attempt to explain the origin of death as a direct adaptation due to selection was probably a mistaken one.

As to the location of the germ-plasm in the sex cells Weismann maintained that it was to be found in the chromatic substance of the nucleus. He held that the chromosomes ("idants") were composed of smaller units, the chromomeres ("ids"), and that the latter were composed of "determinants" or inheritance units, while the most elementary units of life he called "biophores." Both chromosomes and chromomeres are visible structures of the cell. Determinants and biophores are ultra-microscopic in size, but recent work on heredity and development has shown that there is good evidence of the existence of such units. All recent work in genetics is based upon the hypothesis that there are units or factors or determiners in germ-cells which condition the development of adult characters, and though there may be minor differences between these *determiners* of modern genetics and the *determinants* of Weismann, no one can fail to note the genetic connection and the family resemblance between the two.

His prediction on purely *a priori* grounds that one of the maturation divisions in the formation of the egg and sperm should be a "reduction division" whereby the chromosomes of the sex cells should be reduced to half the number present in the somatic cells, whereas all other cell divisions should be "equation divisions" in which the chromosomes should divide equally, was almost as brilliant an example of scientific

prophecy as was the prediction of the existence of the planet Neptune.

Similarly Weismann's assumption that the determinants are arranged in a linear series in the chromosomes finds strong support in the newest and most striking discoveries in this field, in which Morgan is able to locate at different points along the length of a chromosome the determiners of many developed characters.

Finally there is at present universal agreement to the declaration of Weismann that no purely epigenetic theory of heredity is possible, though for many years even this was hotly contested. When one recalls the storm of opposition which was called forth by his book on "The Germ-Plasm" the present acceptance, at least in principle, of his major propositions can not be viewed in any other light than as a triumph for his theory and a tribute to the insight, foresight and constructive ability of Weismann.

As a result of his theory of heredity Weismann was led to investigate the generally accepted doctrine of the inheritance of acquired characters. He carried on extensive experiments in order to learn whether mutilations of parents through many generations were ever inherited by offspring; he investigated many supposed cases of the inheritance of such characters, and as a result of this work he was led to deny altogether the possibility of the inheritance of acquired characters, and he challenged the world to furnish any satisfactory proof of such inheritance. This work of Weismann's called forth a tremendous amount of discussion and a relatively small amount of direct observation and experiment, and for several years it appeared as if no progress whatever was being made toward the solution of this great question, so full of importance, not merely for the biologist, but also for the practical breeder and indeed for the human race. But grad-

ually there has grown up a clearer understanding of the problem and of what is meant by "inherited" and "acquired" characters, and gradually this dead-lock of opinions is breaking up. Now we recognize that inherited characters are those whose distinctive or differential causes are in the germ cells, while acquired characters are those whose differential causes are environmental. No one to-day believes that the developed or somatic characters of an organism are transmitted to the next generation. To-day the problem of the inheritance of acquired characters is merely this: Can changes in the environment change the constitution of the germ-plasm so as to produce changes in subsequent generations? No one now asks whether changes in developed characters may be transmitted to descendants, as was generally done before Weismann's work, for it is generally recognized that somatic characters, whether inherited or acquired, are not transmitted from generation to generation, the only thing which is transmitted being the germ-plasm. Weismann admitted in his later writings that the germ-plasm might be modified to a limited extent by certain environmental conditions, but he held that such changes of the germ-plasm led to general and unpredictable changes in future generations which might be wholly different from those somatic changes in the parents which were directly produced by such environment. This view is now widely accepted.

Thus while Weismann's views on this subject underwent certain changes in the course of his long life, the opinions of his opponents have undergone so much greater and more important changes that it may be truly said that in the matter of the inheritance or non-inheritance of acquired characters the greater portion of the scientific world has come to Weismann's position.

Finally, mention must be made of Weismann's theory of evolution which was a direct outgrowth of his theory of heredity. He maintained that evolution must depend upon an evolution of the germ-plasm and that this was brought about chiefly, if not entirely, by the mixture of different kinds of germ-plasmas (amphimixis) in the union of the sex cells. There is no doubt that many variations are produced by amphimixis, but in general these combinations of germ-plasmas are not actual fusions; new combinations of inheritance units are produced, but not new units, and usually these new combinations split up in subsequent generations according to Mendelian rules, so that such temporary combinations of different germ-plasmas do not usually lead to permanent modification, or to evolution, of the germ-plasm. On the other hand, it is probable that Weismann underestimated the possible influence of environment in producing changes in the germ-plasm and hence its influence on evolution; at least it does not seem possible at present to explain the origin of many inherited mutations except by the influence of changed environment upon the developing germ cells.

In his belief in natural selection Weismann out-Darwined Darwin or any of the Darwinians. Darwin dealt only with the survival of individuals or races in the struggle for existence and was always inclined to assign a good deal of weight to the influence of environment in producing new races. Weismann would not admit the existence of any other factor of evolution than selection and he extended this principle from individuals or persons ("personal selection") to organs and tissues ("histonal selection") and even to germinal units such as determinants and biophores ("germinal selection"). By means of an assumed struggle for nutriment between different determinants he believed

that the weaker ones would tend to grow still weaker and to disappear, while the stronger ones would increase in strength until they reached such importance that they were checked, or increased, by personal selection. And by a similar struggle between different biophores he showed that the *quality* of a determinant would be changed. By means of this highly ingenious but purely formal and hypothetical system he was able to explain the degeneration and disappearance of useless parts of an organism and the concordant modification of many different parts in the course of evolution.

Of all his theories those which grew out of his belief in the "Omnipotence of Selection" have found least confirmation in subsequent work. The mutation theory of de Vries has come in to modify in certain important respects the theory of Darwin, and the work of Johannsen, Jennings, Pearl and others has shown that even "personal selection" has little or no influence in *creating* new types. And yet we have not seen the end of the selection doctrine. The elimination of the unfit is still the only natural means of accounting for fitness in organisms, and we may well ponder these words of Weismann in the preface of his last book:

Although I may have erred in many single questions which the future will have to determine, in the foundation of my ideas I have certainly not erred. The selection principle controls in fact all categories of life units. It does not create the primary variations, but it does determine the paths of development which these follow from beginning to end, and therewith all differentiations, all advances of organization, and finally the general course of development of organisms on our earth, for everything in the living world rests on adaptation.

Clear thinking is necessary in the advance of science as well as fine technique, and Weismann has demonstrated to a more or less scornful world the importance of

brains as well as of hands and eyes in the discovery of truth. It does not fall to the lot of any man to make no mistakes, and in this respect Weismann was only human. But it has fallen to the lot of few men to do so much work of lasting value and to have so profound an influence on his day and generation as was true of August Weismann. The spirit of his life and work may be summed up in the beautiful words with which he closes his essay on "Life and Death":

After all it is the quest after perfect truth, not its possession, that falls to our lot, that gladdens us, fills up the measure of our life, nay! hallows it.

EDWIN G. CONKLIN

PRINCETON UNIVERSITY,
January, 1915

THE PLACE OF WISDOM IN THE STATE AND IN EDUCATION¹

So soon as men get to discuss the importance of a thing, they do infallibly set about arranging it, facilitating it, forwarding it, and rest not till in some approximate degree they have accomplished it.—CARLYLE.

THIS, doubtless, is a true statement; the difficulty is, however, to persuade men of the importance of a thing. We come to persuade you. As an association we are now eighty-four years old: our main purpose has been to obtain a more general attention to the objects of science and a removal of any disadvantages of a public kind which impede its progress—let me also add, its application to culture and to the public service.

By holding meetings, year after year, in the principal towns of the British Isles, the association has at least brought under notice the fact that science is a reality, in so far as this can be testified to by several hundreds of its votaries meeting together each

year to consider seriously and discuss the progress of the various departments. On the whole, dilettanti have had little share in our debates. The association has already carried the flag of knowledge outside our islands, thrice to Canada and once to South Africa; now, at last, we make this great pilgrimage to your Australian shores; still we are at home. What message do we bring with us?

In 1847, when this city was but an insignificant town, it was visited by an Englishman who afterwards became eminent not only in science, but also as a literary man—Thomas Henry Huxley; he was then surgeon on board the surveying-ship *Rattlesnake*. In 1848 Huxley visited Sydney, and there met the gracious lady, only recently deceased, who became his wife. In after years he achieved a great reputation on account of his services to education.

Lecturing in London in 1854, he defined science as "trained and organized common sense"—a definition often quoted since; none could be more apposite, though it must be remembered that "common sense," after all, is but an uncommon sense.

A few years later, in a public lecture at South Kensington, Huxley spoke to the following effect:

The whole of modern thought is steeped in science; it has made its way into the works of our best poets and even the mere man of letters, who affects to ignore and despise science, is unconsciously impregnated with her spirit and indebted for his best products to her methods. I believe that the greatest intellectual revolution mankind has yet seen is now slowly taking place by her agency. She is teaching the world that the ultimate court of appeal is observation and experiment and not authority; she is teaching it the value of evidence; she is creating a firm and living faith in the existence of immutable moral and physical laws, perfect obedience to which is the highest possible aim of an intelligent being.

But of all this your old stereotyped system of education takes no note. Physical science, its methods, its problems and its difficulties, will meet

¹From an address to the Educational Science Section of the British Association at Melbourne, by Professor Henry E. Armstrong, F.R.S., The Central Technical College, London.

the poorest boy at every turn, and yet we educate him in such a manner that he shall enter the world as ignorant of the existence of the methods and facts of science as the day he was born. The modern world is full of artillery: and we turn our children out to do battle in it equipped with the shield and sword of an ancient gladiator.

Posterity will cry shame on us if we do not remedy this deplorable state of things. Nay, if we live twenty years longer, our own consciences will cry shame on us.

These words were uttered in 1861. Now, after more than fifty years, not twenty, merely, we still go naked and unashamed of our ignorance: seemingly, there is no conscience within us to cry shame on us. I have no hesitation in saying that, at home, at all events, whatever your state here may be, we have done but little through education to remedy the condition of public ignorance which Huxley deplored. In point of fact, he altogether underrated the power of the forces of ignorance and indifference; he failed to foresee that these were likely to grow rather than to fall into abeyance. In England, what I will venture to term the Oxford spirit still reigns supreme—the spirit of the literary class—the medieval spirit of obscurantism, which favors a backward rather than a forward outlook.

Wherein was Huxley out in his forecast? In 1861 the claim of science was already strong, but think what has been done since that time—what we can now assert of its conquests! In the interval, even within my recollection, the whole of our ironclad fleet has been created, rifled cannon, smokeless powder and dynamite have been introduced, and this last, in combination with the discovery of the causes of yellow fever and malaria, has made the Panama Canal possible, an entirely revolutionary work of man's interfering hands. The *Great Eastern*, which could not be launched at first on account of her size—as a lad, I saw her sticking in the stocks—was always a

failure, because she was outside the fashion of her time, yet has given rise to a host of ocean leviathans of far larger size; the steam-turbine has entered into rivalry with the reciprocating steam-engine; cold storage has revolutionized ocean transport, so that fresh food can be carried from this continent to remote England and Europe. Electricity, then a puling infant, is grown to giant size; not only have we deep-sea telegraphy and mechanical speech in the form of the phonograph and telephone, but wireless communication, the electric light, electric transmission of power, electric traction—even the waterfalls of the world are tamed through the turbine and made subservient to our will for motive purposes or in the production of temperatures bordering on those of solar heat, by means of which, too, we can draw food for plants, at will, from our atmosphere, by combining its constituents into the form of a fertilizer. The use of oil-fuel in the internal-combustion engine has been made possible and, in a few short years, our streets have been cleared of horse conveyances and crowded with motor-vehicles; such engines are coming into use everywhere and have enabled us successfully to perform the feat which Dædalus vainly attempted—we even talk of flying from New York to London, across the vast Atlantic, to spend the week-end. The cyanide process has been introduced into gold-mining and is enabling us to unearth a fabulous wealth; a vast array of gorgeous colors has been produced, and Dame Nature so outwitted that we make indigo and madder out of the tar which in old days was put only upon fences; Pasteur's work has made Listerism possible, so that nothing is now beyond the surgeon's art and bacteriology is become the handmaid of preventive medicine and sanitary science; not only paper, but a silk is made artificially from wood-pulp and the finest of scents are conjured

out from all but waste materials. A multitude of other discoveries of practical value might be referred to.

Not so long ago, when scientific research was spoken of, the cry was always, *Cui bono?* What's the good of it all? Now, no one has the patience to listen to a recital of the benefits accruing to mankind from its operation; for all the achievements I have referred to are *not the work of mere inventors*, but primarily the outcome of scientific discovery: thus our modern command of electricity is very largely traceable to the labors of the great philosopher Faraday, who worked in an ill-lighted and cramped laboratory in the Royal Institution in Albemarle Street, London, with no other object than that of contributing to the advancement of knowledge.

Perhaps the greatest of all the scientific achievements of our time remains to be mentioned—the promulgation of the doctrine of evolution by Charles Darwin. Few, perhaps, can realize what this means for mankind, the intellectual advance it constitutes—that through it we have at last acquired full intellectual freedom and the belief that it rests with ourselves alone rightly to order our lives; that by it all dogmas have been undermined.

Science is come into being and has prospered only since freedom of thought was secured: on no other terms can it be. It is well that we should bear this in mind. The growth of numbers and of democracy may well involve a restriction of freedom in all directions—none are so intolerant as the ignorant.

If in science, to-day, we have something unknown to former civilizations, what is its influence to be on the future of the world, in particular on the future of the white people? If we are not to suffer the rise and fall which all previous civilizations have passed through—rather let me say, if

the period of our fall is to be retarded beyond the period our forerunners enjoyed, it will be solely because we wield and use the powers science has put into our hands: not so much those of abstract science, but the broad wisdom which the proper cultivation of science should confer; hence it is that I desire to urge the absolute importance of giving, through science, a place to the cultivation of wisdom in the state and therefore in education.

Clearly, two new forces are at work in the world: not science alone, but also a broad and altruistic socialism, both the outcome of the intellectual freedom man has acquired since the deposition of the churches. The one is gradually leading us to base our actions upon knowledge and to be practical through the use of theory; the other is leading us gradually, though slowly, to have consideration for one another, to recognize how helpless are the majority, how greatly they stand in need of the guidance of the few who are capable of leading. But we shall need to order our socialism by science to make it a wise socialism. The signs are only too numerous that a wave of political despotism may come over us. Either, as time goes on, science will be more and more of service in guiding the social machine—or that machine will perish, from the very complexity of its organization and the inability of the units to understand their place, to understand the need of subordinating their individual inclinations to communal interests; most important of all, to understand their inability to recognize and require competent leadership—for science is aristocratic in its tendencies: indeed, I shall claim that real science—wisdom—is for the very few.

With all the marvelous growth of achievement to which I have referred, there has been no proportionate growth of public intelligence. Our admiralty, and to a far

less extent our war office, have called science into their service, but our public departments generally will have none of it. Even the elements of an understanding of the methods of science are not thought to be essential to the education of a civil servant; such knowledge is not required even in the highest branches of the Indian service—no politician is for one moment supposed to need it: we are governed almost entirely by the literary spirit.

The spirit of the age, in fact, is in no way scientific, though ease and comfort are now provided on an unprecedented scale through the agency of science, the engineer acting as chief interpreter. Why do we still go naked and unashamed of our ignorance of "science"? One main reason is that the party in power is unscientific; but at bottom, I believe, the difficulty is a far greater one and probably innate in our disposition. It can not well be supposed that man is by nature disposed to be scientific. The scientific fraternity, at any time, are, and probably always will be, but a small party—a set of freaks, sports from the multitude. They think and talk in a language of their own, as musicians do. The multitude may listen to them at times, with more or less of pleasure, as they do to music; but it is impossible, and probably always will be impossible, for the many to appreciate the methods and results of the scientific worker. Science, in reality, is a form of art, and true artists are never numerous; moreover, it is admitted that they are born—like Topsy, they must grow, for they are not to be made in numbers. Our schools are for the most part in literary hands: and it would almost appear that literary and scientific interests are antagonistic, so unsympathetic has been the reception accorded to science by the schools.

Parenthetically, let me here deny the accusation not infrequently made by literary writers that the scientific fraternity are

trying to oust literary studies from the schools. Nothing could be further from the truth. We are always craving for better literary training; our complaint is that the methods and subject-matter of literary training are far from being properly developed and, especially, that English is neglected in the schools. Huxley stated the real situation in saying,

Science and literature are not two things, but two sides of the same thing.

The rise of science is due to the introduction of the experimental method. Mr. Balfour, in arguing, as he has done recently, that science rests upon many unprovable postulates and therefore does not differ in method from metaphysics, has made assertions which can not be allowed to pass as correct. True science rests wholly upon fact and upon logic: all else is mere provisional hypothesis—a garment we are prepared to put aside at any moment if cause be shown. We are well aware that human nature is always intervening to spoil our work; it is human to err and false doctrine may easily occupy the attention for a time, but we are fully conscious of our limitations and prepared to admit them, whilst we feel that we are ever advancing towards security of knowledge.

The method of science, indeed, is the method of the Chancery Court—it involves the collection of all available evidence and the subjection of all such evidence to the most searching examination and cross-examination. False evidence may be tendered and for the time being accepted; but sooner or later the perjury is discovered. Our method, in fact, goes beyond that of the courts: we are not only always prepared to reconsider our judgments, but always searching for fresh evidence; we dare to be positive only when, time after time, the facts appear to warrant a definite conclusion. But there are few instances in

which we have traveled so far. The Newtonian theory of gravitation, the Daltonian theory of atoms, are two striking examples of generalizations which fit all the facts, to which there are not known exceptions; should any exception be met with we should at once doubt the sufficiency of such theories. In cases such as Mr. Balfour has discussed—the problems of metaphysics and of belief—experiment and observation are impossible: we can only resort to speculative reasoning; our belief, if we have one, is necessarily founded upon intangibilities and desires.

There was a door to which I found no key;
There was a veil past which I could not see;
Some little talk awhile of Me and Thee
There seemed—and then no more of Thee and Me.

The awful problem before us at the present time is to decide which direction we will take, to what extent and in what way we have the right to teach things which transcend our knowledge; the way in which truth lies may be clear to some of us, but can never be to the majority. Those who wrap up such matters in a tangle of words are not helpful, to say the least. However mellifluous the terms of Bergsonian philosophy may be, they do not bear analysis when the attempt is made to interpret them; their effect is merely sensuous, like that of cathedral music.

But in order that she may lead, science must herself set an unimpeachable example—far too much that is now taught under the guise of science is pure dogma; in fact, the philosophy of the schools is mostly dogma. The true legal habit of mind is insufficiently cultivated and but rarely developed even among scientific workers—our logic is too often imperfect. In science, as in ordinary life, party politics run high and scientific workers are usually, for the time being, party politicians. We are too often, *crass* specialists, always very

human: indeed, whatever the lines along which evolution has taken place, they can not well have been such as to favor in any considerable degree the development of the proclivities which distinguish the scientific inquirer: time after time, doubtless, he has been knocked on the head.

The difficulties under which science labors in our schools are partly internal, partly external. Tradition and the type of mind of the average teacher favor set lessons and literary study by blocks of learners; the extra cost of the work is considerable, when the expense of the special requirements is taken into account; more time and more individual effort are demanded both from teacher and from taught; freedom is hampered by the need of considering the requirements of external examinations; finally, the universities have done but little to help, and though the schools have more or less unwillingly recognized that there is some value in scientific studies, in consequence of the persistent demands men such as Huxley have made, more especially because it is seen that there is money in them, none the less there is still no real demand for them on the part of the public. Of this and, in fact, of nearly all the real problems of education, the public are too ignorant to be judges.

Having been more than forty years not only a teacher, but also a student of students and of teachers, of educational methods, and of the conditions under which teaching is carried on, I have been led to form very definite opinions, the more so as I have been able to regard the problems not only from the pedagogic side, but also from that of the chemist and biologist—with some knowledge of the mechanism.

My view—and it is one that I desire to press to a logical conclusion—is that we must recognize that human ability is not merely a limited quantity, but that it varies

enormously not only in quantity, but also in quality: the human orchestra contains a great variety of instruments differing in tone and range, but nature, like man, makes few instruments of superlative excellence, a vast number of very poor quality and only a moderate proportion of serviceable type. If science can tell us anything, it is that the democratic and republican ideal of equality is the veriest moonshine—a thing that never has been and never will be. And education can do very little to alter the state of affairs: it can not change the instrument, at most it can develop its potentialities, and it may easily, by careless handling, do damage to the working parts. To take a special case, of interest at the moment, no contention is less to be justified, I believe, than that which has been put forward frequently, of late years, on behalf of women—that their disabilities are in no small measure due to the fact that we have neglected their education: give them time to educate themselves and they will be as men in all things. Years ago, at our Stockport meeting, I ventured to express the difference by saying that woman is not merely female man, but in many respects a different animal: the two sexes have necessarily been evolved to fulfil different purposes. Nothing is more instructive in the history of modern educational progress than the fact that women have asked merely for what men have: at the universities they have attended the men's courses; not one single course have they demanded on their own account. Higher teaching in relation to domestic science so-called has only been thought of very recently and mainly because men have urged its importance. Most serious and, I believe, irreparable injury is being done to women, in London especially, by forcing them to undertake the same studies and to pass the same university examinations as the men: and the

damage is done to the race, not merely to individuals, as the effect of education, whether direct or indirect, is clearly to diminish the fertility of the intellectual. Some day, perhaps, when the present wave of selfishness has passed over us, a rational section of women will found a woman's university where women can be taught in ways suitable to themselves without injury to themselves. In saying these things, of course, I am laying myself open to the charge of narrowness—in deprecation I can only say, that what we are pleased to call education is, for the most part, so futile in substance and in its results that I shall not mind in the least if I am accused of decrying it: in my opinion, we shall all be better without most of it, men and women alike. So far as so-called intellectual education is concerned, learning to read seems to me to be the one thing worth doing: at present it is the thing most neglected in schools.

To develop a rational system, we need to take into account man's past history and to apply evolutionary and biological conceptions. Education, as we know it and practise it, after all is a modern superstition—something altogether foreign to the nature of the majority of mankind; it is based on the false assumption that we can all be intellectual; whereas most of us can only use our hands. But the schools neglect hands and attempt the impossible by trying to cultivate non-existent wits. Man is doubtless pretty much what he was, and it is useless trying to make of him what he has never been.

We are seeking to educate all. What does this mean? Practically that we are seeking to teach all to read. But when they have learned, what are the majority to read—what will they care to read? At the schools for young gentlemen, the reading taught hitherto has been mostly the reading

of Latin and Greek. We know the result—the number of persons above school age who can and do read either language is negligible. Some of us learn French, scarcely any learn German, Spanish is all but neglected: when, therefore, we visit the Continent of Europe or South America we can only mumble a few words of the language of the country, and usually allow the foreigner we visit to speak broken English for us; few of us read his literature.

The vain attempt is made to put us in touch with the past, but no real effort is exerted to bring us into contact with the present. We have not yet taught English in our higher schools, but are beginning to think of doing so—to this end, we are urging that attention be paid to so-called classical literature, forgetting, of course, that for the most part this was written for grown-ups and not as food for babes of school age.

The difficulty is still greater in the case of those who have only passed through the elementary schools—the literature that will appeal to most of these will be very limited in scope. Our newspapers show pretty clearly what will go down: not much—but it represents what is going on in life. In London, when the theaters are under discussion, it is often said that people want to be amused, not instructed; to cudgel our dull brains is a dull business to most of us. It seems to me that this doctrine should be applied more than it is in the schools. At all events, we shall do well to remember the words of the wise pundit in Rudyard Kipling's "Kim": "Education—greatest blessing when of best sorts—otherwise no earthly use."

To discover the best sort for each sort of student is our difficulty—who will do it? Here comes my point. Not the present race of schoolmaster or of educational authority. By placing classical scholars in charge, we

seem unconsciously to have selected men of one particular type of mind for school service—men of the literary type; and this type has been preferred for nearly all school posts, mainly because no other type has been available, this being the chief product of our universities. Such men, for the most part, have been indifferent to subjects and methods other than literary—I verily believe not because they have been positively antagonistic or lacking in sympathy, but rather because of their negative antagonism: of an innate inability to appreciate the aims and methods of any other school of thought than their own, especially on account of their entire ignorance of the experimental method. I believe, moreover, that the difference is fundamental and temperamental, not to be overcome by training. Oxford, owing to the bait of its classical scholarships, seems to have attracted an entirely peculiar type of ability and to stand alone in consequence; at Cambridge, owing to the hold obtained by mathematics, the field has been divided, but the mathematician, in his way, is often as unpractical by nature as the classic; fortunately, of late years, owing to the rise of the medical school and that of natural science, other elements have been introduced and the university has a future of infinite promise in consequence, if it will but realize that its primary function is to inculcate wisdom rather than to give purely professional training.

Sympathy is only begotten of understanding; the literary type of mind apparently does not and can not sympathize with the practical side of modern scientific inquiry, because it has neither knowledge of the methods of experimental science nor the faintest desire for such knowledge.

We need a more practical type of mind for our schools. Pessimist though I may appear to be, having watched with close

attention, all my life, the great struggle that has been going on in and between schools—having had the great good fortune also myself to be one of the early workers in the province of technical education, and having been associated with the development of one of the greatest of our boarding schools (Christ's Hospital)—I am, of course, aware that very great progress has been made, and am, in every way, hopeful of the future in store for those who are unaffected by present prejudices. In my experience, the men to whom the progress has been due have, in all cases, been trained in a broader school than that of Oxford; the few escapes from Oxford who have been successful reformers have been the exceptions which prove the rule, as they have shown themselves to be gifted with practical instincts: to such men the Oxford literary training has been of extreme value. Oxford will not gain its full value until all types of ability are represented in fair proportion by its students, not one almost exclusively. When this step is taken, the incubus of the Oxford spirit will no longer be upon us: it will then be possible for us to regard education as "a preparation for life"—a formula often used but usually honored, hitherto, in the breach, rarely if ever in the observance, in our schools.

There must be no misunderstanding. The representatives of literary training rely chiefly on a past into which it is well not to look too closely and must always work with borrowed capital in the days to come: our side has no distant past worth speaking of, but is hopeful of a glorious future, in that it will always be adding to its knowledge; we desire to do their party all possible justice, and shall ever be in need of their assistance and more than grateful for the service they render us; but it must be war to the knife if they will not recognize that, in a progressive age, they can not lead any

longer, that we shall decline to put up in future with the conceit and narrowness of outlook of the classical scholar.

The argument I have applied to the teacher is equally applicable to the taught—boys and girls, indeed students generally, are of different types; they have different orders of ability and can not be treated as if all were alike. In the beginning, we may tempt them with all sorts of scholastic diet, but only, in the main, in order to discover their aptitudes; when these are found, they should be the main line of attack. In saying this, I am not arguing in favor of extreme specialization, but against time being wasted in attempting the impossible. Some of us can learn one thing, others another: the schools try to force too many into one mould. It is essential that we should try to lay certain foundations, but useless to proceed when we find that some of them can not be laid.

This doctrine is applicable especially to the selection of scholars and to the training of teachers and of evening-class students. We select our scholars almost entirely by literary tests—the result is that we select persons of literary aptitude rather than those gifted with practical ability for every kind of service: like necessarily breeds like. By insisting on "grouped courses" we too often oblige students to take up subjects to which they are incapable of paying attention with profit: most of us, probably, have found out that there are many subjects which we simply can not learn, try as we may.

My own experience with students has satisfied me that they not only vary in ability, but that the different classes are of very different types of mind: the engineer tends to be constructive, but not analytical; the analytical introspective habit of mind is more highly developed in the chemist; the biologist rarely has mathematical procliv-

ities. It is useless to attempt to teach all in the same way, and many can learn only very little.

The explanation of Huxley's failure to forecast the future of science lies, apparently, in the fact that men generally are not attuned to her ways. I am inclined to think that the "mere man of letters" *will continue* to ignore and despise science—he will lack the peculiar mental capacity to assimilate scientific teaching. Only the few will rise to a proper understanding of the mysteries and be masters of their subjects, though many may be trained to be skilful mechanics.

The extent to which the multitude can receive instruction is a matter of primary importance. If, as Huxley has said, the greatest intellectual revolution mankind has yet seen is now slowly taking place by the agency of science—if she be teaching the world that the ultimate course of appeal is observation and experiment, not authority; teaching it the value of evidence: then must we strive to teach all, in some measure, what constitutes evidence, what observation and experiment are.

I believe much can be done in this direction, having made the attempt with hundreds of unwilling students in my time, students of engineering who had not only made up their minds that they were not going to learn chemistry as it was not their subject, but were incapable of ever entering into the spirit of the work—one of my sons was amongst them. At an early period, having realized that it was useless to waste my time and theirs in the struggle, and that it would not help them in the long run, to give them chemical tips which they lacked the sense to appreciate and to apply, I made up my mind, therefore, that it was desirable instead to develop any detective or inventive spirit that might be in them, so advised them to read defective stories

instead of a text-book and ask themselves what the stories taught them: how the detectives set to work. Their attention was secured by urging them also to think what would be their position, later in life, when they were called upon to act for themselves and to get new knowledge for themselves, if they had not learned to think for themselves. We have then set them to work to solve a series of problems in the laboratory. The course, in fact, was a combined laboratory-lecture course, the lectures being on and always subsequent to the laboratory work. In not a few cases, in after years, when I have met old students, they have told me spontaneously that, much as they had objected to the pressure put upon them, our insistence on their learning to do something themselves had proved to be of extreme value. Long experience has convinced me that any one who has once learned to make simple measurements and observations and to ask and answer a definite question experimentally is on a different mental and moral plane from that occupied by those who have had no such training.

Such teaching is possible even in elementary schools—given competent teachers; but a new race of teachers will be required to carry the work into effect, should it be decided to make the attempt at all generally.

The great mistake that has been made hitherto is that of attempting to teach the elements of this or that special branch of science: what we should seek to do is to impart the elements of scientific method and inculcate wisdom, so choosing the material studied as to develop an intelligent appreciation of what is going on in the world. It must be made clear in every possible way, that science is not a mere body of doctrine, but a method: that its one aim is the pursuit of truth.

If we are to progress in these matters, a system must soon be developed which is broader and better than that under which we now muddle along—at present the real problems of education are all but neglected; even if the official mind were capable and desirous of promoting progress, the work of administering rules and regulations—of keeping the machine going—is so great that no time is left for thought.

We have seen the error of our ways sufficiently to give up payment by results, and are all but ashamed that we were ever misled by Robert Lowe to adopt such a soul-killing policy. But none the less our entire educational system is still in the grips of commercialism, and, in this respect, as a nation, we stand alone, I believe. Scholarships, prizes of one kind or another, examinations are the perpetual feast of British education. Examinations, in fact, are a regularized and very lucrative branch of industry—mostly in the hands of certain firms who diplomatically shelter themselves under the ægis of this or that educational body; but the universities are the greatest sinners. Valuable as examinations may be within certain narrow limits and for certain definite purposes, there is little doubt that our general ignorance is in no small degree determined by our worship of the examination fetish. So long as the system prevails, the education of our youth will not be in accordance with either their capacity or their requirements, but on lines corresponding to those by which prize cattle are raised for show—they will be trained to develop some specially catching point.

The examinations are an inheritance from the literary rule. It is possible to test on paper whether a man be "well read," but faculty as distinct from capacity can not be so determined. What is worse, by forcing students to commit a large body of doctrine

to memory, the attention becomes fixed merely upon what others have done and little time or inclination is left them to acquire a knowledge of method—the faculty of thinking for themselves and applying their knowledge. No class suffers more seriously than medical students under the system—their preliminary training is all but entirely didactic, and the time spent upon it all but wasted; we need not wonder that medicine has made so little advance, the practitioners being in no way trained in the use of scientific method.

To improve our system we need to get rid of our blind British belief in "men of affairs," especially in the "man of business," so-called, really the man of commerce, as persons capable of ordering everybody's affairs and everybody's business. The commercial man, the financier or the lawyer, would never think of calling us in to manage his proper business—why should he be thought competent to manage ours? Results show that he is not, as my argument in this address would lead us to expect would be the case.

No one will seek, for one moment, to minimize the progress made or fail to recognize that infinite credit is due to those who have controlled the work of education thus far; hitherto, however, progress has been made in providing accommodation and getting scholars to school and college: the art of teaching has made no corresponding advance—nor will it, I believe, until the onus is cast more directly upon the teachers and they are forced to exercise greater forethought in the direction of collective action—until they are placed in a position to be sole managers of their own affairs and called upon to row together as entirely self-chosen crews. At home, excepting at our ancient universities, "governing bodies" are paramount everywhere—not the teachers; and too often the sense of

responsibility and power of initiative of the teacher are further diminished by the interposition of a principal, who may be a man of all affairs except that in hand—the work of teaching.

If the conclusion at which I have arrived be correct—that science is not for the multitude and can never be generally appreciated or even fashionable—in view of the part which it is clearly destined to play in education and in daily life, on account of its infinite and far-reaching influence upon our well-being—the responsibility cast upon the few representatives of science is very great; in support of our civilization and in order that wisdom may prevail more generally, they must organize its forces effectively.

Whilst individuality is the mainspring of scientific progress, collective action is required to provide full and proper opportunity for the workers and to promote the success of their inquiries. At present, scientific workers are organized merely for the purpose of providing means of publishing the results of their studies, in no way either for defence or offence; our societies are not effective even for the purposes of debate and criticism. Thus, our chief English scientific society, consisting of some 500 members representative of all the various branches of physical and biological science, is little more than a rabble—its fellows are such individualists that scarce half a dozen of us can ever agree to work seriously together for a common purpose, and the irresistible influence we might exercise if we could be unanimous as to our objective is lost to the community. Most unfortunately, the society has no influence whatever either on political or on public opinion; it makes no attempt either to guide the public or to give dignity and importance to the cause of science in the eyes of the community. Its meetings are dull, and its

belated publications by no means represent the scientific activity of its fellows. The presidents of the society have too often been appointed at an age when the propagandist spirit is no longer paramount, when they have no particular scientific message left in them to deliver. And they occupy the chair too long; this arises chiefly from the fact that however clear each one of us may be that individually he is fully competent to hold the office, we all agree in finding some objection to every name that is suggested; to overcome this difficulty a short tenure is desirable, so that the compliment can be paid and encouragement given to the various sciences in turn; no one should be appointed to such an office who is more than sixty to sixty-five years old, as most of us have used up our ideas and have lost our virility by that age. The other officers also hold their positions too long, but members of the council have far too short a life—consequently all the power is centered in the official body; attempts that have been made to organize the whole society in sections representative of the various sciences have always been defeated by the official party.

Unless our scientific societies can be made more generally effective, if scientific workers are incapable of learning lessons from administrative life, it stands to reason that the collective interests of science and of the body scientific must remain unrepresented and unvoiced—to the great detriment of progress and of the public.

Science must be organized, in fact, as other professions are organized, if it is to be an effective agent in our civilization; the problems pressing upon us are of such magnitude and of such infinite importance that we can no longer afford to be without wisdom.

HENRY E. ARMSTRONG

**THE SAN FRANCISCO MEETING OF THE
AMERICAN PHYSICAL SOCIETY**

THE American Physical Society will unite with Section B of the American Association for the Advancement of Science in a joint meeting to be held at San Francisco August 2 to 7, 1915.

The program of the meeting is in special charge of the Pacific Coast Committee of the American Association for the Advancement of Science and will differ somewhat from that of ordinary meetings. The presentation of the results of individual research in short papers volunteered by their authors will be a minor feature of this meeting, but several sessions will be devoted to a somewhat broader consideration of the larger questions of physics, particularly those which have engaged the attention of Pacific coast workers. At these sessions only papers given on invitation will be presented. One session will probably be devoted to spectroscopy and another to atmospheric physics, the latter in charge of Professor W. J. Humphreys.

On Wednesday, August 4, the society will visit Stanford University and Professor Harris J. Ryan will give demonstrations with high-potential electric currents in the new laboratory especially equipped for such work. The meetings on other days will be held at the University of California at Berkeley. On Friday the officers of the Physical Society will have charge of a session—or two if necessary—at which ordinary research papers will be presented. It is hoped that the western workers who do not often have an opportunity to attend our meetings may be conspicuous on this program and their contributions are especially requested. Visiting members from the east are not urged to present many papers, as time will be somewhat limited.

Physicists are invited to attend the joint sessions of the American Mathematical Society and the American Astronomical Society at Berkeley, Tuesday forenoon, August 3. An address will be given by Professor O. J. Keyser, of Columbia University, New York, on "The Human Significance of Mathematics," and by Dr. George E. Hale, of Mt.

Wilson Solar Observatory, on "Recent Progress in the Development of Astronomical Science."

An excursion to Lick Observatory has been arranged for Friday, August 6, by the American Astronomical Society. The observatory may also be visited on any day of the year from 8 A.M. to sunset, and on Saturday evenings by those arriving before 9 o'clock. Saturday evening visitors have the privilege of observing the stars with the 36-inch and 12-inch telescopes. The railway station for the Lick Observatory is San Jose. An auto-stage leaves San Jose on six days of the week at 8:30 A.M., stops at Smith Creek Hotel for luncheon and reaches the summit of Mount Hamilton before noon. The stage departs at 1:30 P.M. and reaches San Jose before 4 P.M. The round trip fare for the individual trip by auto-stage is \$5.

The director of the Mount Wilson Solar Observatory extends a cordial invitation to men of science interested in astronomical and physical research to visit the observatory either before or after the San Francisco meeting of the association. The shops and laboratories in Pasadena and the observatory buildings on Mount Wilson will be open, and all phases of the work in progress can be seen. The Mount Wilson Hotel Company maintains a daily auto-stage service between Pasadena and the summit, where comfortable accommodations for the night may be found at the hotel. If time is limited, the round trip from Pasadena can be made in a day. The auto-stage leaves the office of the company (173 E. Colorado Street) at 9:30 A.M., reaching the summit at 11:45 A.M. On the return trip the stage leaves at 3 P.M., and arrives in Pasadena at 4:45 P.M. The round trip fare is \$3.

The director of Congresses of the Panama-Pacific Exposition has organized a special convention news bureau to give due publicity to papers and proceedings of organizations meeting in San Francisco and vicinity. This will include the preparation, in advance of the meeting of articles for the daily press and for magazines, reporting each session for daily press and news agencies and in some

CASES preparing full reports of meetings for magazines.

From New York to San Francisco and return	94.30
From Boston to San Francisco and return...	100.70

Tickets from Chicago, St. Louis and similar territory are good via New Orleans, returning by the same or any other direct route. All rates apply via Los Angeles. Round trip tickets going or returning via Canadian or northern lines through Prince Rupert, Victoria, Vancouver, Seattle or Portland, Shasta Route (rail) or steamship between these points and San Francisco are \$17.50 higher (berth and meals included on steamer from Prince Rupert to Seattle). The usual stop-over privileges will be allowed on both going and returning trip. Journey out may be taken via one route and return by another, and the above rates are good for 90 days from date of sale. Railroads participating in this arrangement include the Grand Trunk, Canadian Pacific, Great Northern, Chicago, Milwaukee and St. Paul; Northern Pacific, Southern Pacific, Union Pacific, Denver and Rio Grande, San Pedro, Los Angeles and Salt Lake, Santa Fe and Mexican Central. The Panama-California Exposition at San Diego is reached by rail from Los Angeles by the Santa Fe Railway and trans-continental excursion tickets by way of Los Angeles will include a trip to San Diego and return without extra charge, but only if arrangement for it is made at the time the trans-continental ticket is purchased.

Special lines of steamers advertise passage

between Atlantic and Pacific Coast by way of the Panama Canal at rates varying between \$135 and \$198 (one way).

Stop-overs for side trips can be arranged either going or returning. Round trip rate from San Francisco to Hawaiian Islands and return by either of several lines of steamers from \$110 up. Yellowstone National Park is reached from Livingston on the Northern Pacific (to Gardner and return \$3.20). A six-day trip in the park from Gardner costs \$40 and another of 5½ days \$53.50. Yellowstone Park may also be reached from Ogden on the Union Pacific by a branch to Yellowstone (round trip \$9.25). From here a five-day trip in the park costs \$35 and a six-day trip \$40.

The Yosemite National Park is reached by Southern Pacific or Santa Fe lines, stopping at Merced, Cal. Round trip from Merced to Valley \$18.50.

Both hotels and comfortable camps may be found at the camp. Several groves of Big Trees may be visited from the Valley. One grove very much visited is only six miles from Santa Cruz (on the Southern Pacific).

Alaska may be visited by steamer trip from Seattle or Vancouver. Round trip from Seattle \$66 and up. From Prince Rupert (on Grand Trunk) a trip to Alaska may be made at an additional expense of about \$30.

The Official Hotel Bureau of the Panama-Pacific International Exposition, with which are affiliated about 85 per cent. of the hotels of San Francisco and vicinity, guarantees that the rates of hotels associated with the bureau will not be advanced during 1915. Schedules of rates of the hotels may be secured from this bureau (address, Exposition Building, San Francisco).

Further information in regard to programs, travel connections, etc., may be secured by addressing Albert L. Barrows, associate secretary, American Association for the Advancement of Science, University of California Library, Berkeley, California.

The columns of SCIENCE will contain further announcements.

A. D. COLLE,
Secretary

SCIENTIFIC NOTES AND NEWS

THE seventieth birthday of Professor Elie Metchnikof, was celebrated in Paris recently, though the international Festschrift planned in his honor has been abandoned. At the exercises Professor Darboux spoke on behalf of the Paris Academy of Sciences and Dr. Roux on behalf of the Pasteur Institute.

MR. THOMAS A. EDISON was given the degree of doctor of science by Princeton University, at its recent commencement.

HONORARY degrees were conferred at the recent commencement of George Washington University upon men of science as follows: doctor of laws, William H. Dall, of the U. S. Geological Survey and the Smithsonian Institution, and Otto H. Tittmann, lately superintendent of the U. S. Coast and Geodetic Survey; doctor of medicine, Shepherd I. Franz, of the Government Hospital for the Insane.

THE University of Pittsburgh has conferred the degree of doctor of science on Reid Thomas Stewart, professor of mechanical engineering and for thirty years a teacher in the University of Pittsburgh.

THE Howard N. Potts gold medal of the Franklin Institute has been awarded to Dr. W. J. Humphreys for his paper "The Thunderstorm and Its Phenomena."

PROFESSOR BASHFORD DEAN, of Columbia University, has been elected an honorary member of the Société Zoologique de France in recognition of his contributions to the embryology of vertebrates.

THE medical faculty of the University of Heidelberg has awarded the Kussmaul medal and the prize from the Kussmaul endowment to the surgeon, Professor Braum of Zwickau.

PROFESSOR HENRIK MOHN, the distinguished Norwegian meteorologist, has celebrated his eightieth birthday.

ADMIRAL SIR HENRY JACKSON, K.C.B., who has been appointed first sea Lord of the British Admiralty, is a fellow of the Royal Society and is known for his researches on electrical physics.

DR. JOHN R. MURLIN, assistant professor of physiology in Cornell University Medical Col-

lege, New York City, has declined the permanent position of biochemist at the pellagra hospital of the U. S. Public Health Service at Spartanburg, S. C. He has also declined the professorship of physiology and physiological chemistry at Fordham University Medical School.

WITH the aid of the fund given to the university by Mrs. Amey Richmond Sheldon, the Harvard division of geology has sent W. G. Foye, assistant in the division, to Fiji. In that archipelago he will study the coral reefs, the uplifted limestones and the volcanic rocks. He will soon be joined by W. M. Mann, of the Bussey Institution at Harvard. Also as a Sheldon fellow, Mr. Mann will specially consider the distribution of organic species in its relation to the origin of the islands and reefs. Their joint investigation is planned to last nine to twelve months. Another Sheldon fellow, Sidney Powers, is spending six months on an investigation of the volcanoes and igneous rocks of the Hawaiian Islands.

DR. JOSEPH E. POGUE, associate professor of geology, Northwestern University, sailed on June 15 from New Orleans for a three months' visit to Colombia, where he will carry on geological studies in the Andes near Bogota.

MAURICE PARMELEE, who took the degree of doctor of philosophy at Columbia University in 1909, has been voted the Squires prize by that university. This prize is awarded quinquennially "to such graduate conducting an original investigation of a sociological character as shall be adjudged most worthy by a committee of award, consisting of the president, the professor of sociology and one of the professors of political economy. Such award shall be deemed to be a recognition of scientific ability and achievement, as well as an encouragement of research." Mr. Parmelee is now engaged in literary work of a sociological nature in New York City.

ANOTHER surgical unit, made up almost exclusively of Harvard surgeons, will sail from New York on June 29 for service in one of the field hospitals of the English army. The location of the hospital has not been

divulged, but it is probably in England. Most of the thirty-four members of the unit have been taken from the staffs of the Boston City Hospital and the Massachusetts General Hospital, but a few have come from suburban hospitals. Dr. E. H. Nichols, associate professor of surgery and visiting surgeon to the City Hospital, will be in charge of the unit. Other senior surgeons are: Dr. William E. Faulkner and Dr. John I. Thomas, both of the City Hospital, and the following from the Massachusetts General Hospital: Dr. Charles A. Porter, Dr. Franklin G. Balch, Dr. Alexander Quackenbush, Dr. Harris P. Mosher, Dr. Walter J. Dodd and Dr. Roger I. Lee, who is professor of hygiene at Harvard.

FREDERICK G. CLAPP, of Pittsburgh, has recently returned from a year and a half spent in geological explorations in China.

THE University of Pennsylvania Museum has heard from its expedition to Siberia, under the leadership of H. U. Hall. A letter has been received from him at Monastir, on the Yenisei River, the first civilized place reached after a long winter within the Arctic Circle, between the Yenisei and the Lena Rivers. The letter was dated April 1, and announced that the river would be open in two months, after which time he would start for the United States.

PROFESSOR ROBERT F. GRIGGS, of the department of botany of the Ohio State University, has left for Kadiak, Alaska, to make investigations for the National Geographic Society on the vegetation of volcanic ash deposited by eruptions of Mount Katmai. His study will be a continuation of similar observations which he made during a trip to Alaska two years ago.

THE commencement address at Case School of Applied Science was delivered by Mr. William C. Redfield, secretary of commerce. The address before the Case Chapter of the Sigma Xi during commencement week was delivered by Mr. Charles F. Brush, on "Early Recollections of the Electric Light Industry."

At the April meeting of the Virginia Chemists Club a telegram was read from Secretary

Chas. L. Parsons, of the American Chemical Society, announcing that the club had been made a section of the American Chemical Society, to be known as the "Virginia Section." Dr. Alexander Smith, of Columbia University, was the guest of honor at this meeting and addressed the club on "The Teaching of Live Chemistry." Dr. Smith was elected an honorary member of the new section.

DR. VICTOR C. VAUGHAN, dean of the medical faculty of the University of Michigan, and president of the American Medical Association, delivered the address at the annual commencement of Jefferson Medical College, Philadelphia, on June 15, his subject being "A Doctor's Ideals."

ON the evening of June 12 Professor Cassius J. Keyser, of Columbia University, made the annual address before the local chapter of the Society of Sigma Xi at the University of Washington. The subject of the address was "Science and Religion, or the Rational and the Superrational." On June 16, he delivered the commencement address at the University of Oregon, speaking on university ideals as the light of life.

It was stated in a recent issue of *SCIENCE* in accordance with information sent us that Professor A. G. Webster had given a lecture at Oberlin College on "Business and Kultur." We are now informed that the title was "Physics and Kultur."

DR. JOHN H. MCCOLLOM, seventy-two years old, professor emeritus of contagious diseases at the Harvard Medical School, died on June 14.

LIEUT.-COL. CHARLES E. WOODRUFF, U. S. A., retired, died on June 13, aged sixty-five years, at his home at New Rochelle, N. Y. In 1886 he entered the United States navy as a surgeon. A year later he resigned and entered the army with the same grade. He was chief surgeon of brigade on General Merritt's staff in the Philippines. He went round the world inspecting the sanitation of foreign army posts and later the sanitary conditions of Germany and several other European countries for the United States government. He was the

author of "The Effect of Tropical Light on White Men" and "Expansion of the Races."

Dr. HUGO MÜLLER, F.R.S., past-president of the British Chemical Society, died on May 23, aged eighty-one years.

SIR A. H. CHURCH, F.R.S., formerly professor of chemistry in the Royal Academy of Arts, London, died on May 31, at the age of eighty years.

THE death is announced of M. Pierre Martin, known for his work on the metallurgy of steel.

DR. OSWALD LOHSE, head astronomer in the Potsdam Astrophysical Observatory, has died at the age of seventy-one years.

GRAND DUKE CONSTANTINE CONSTANTINOVITCH, who died on June 15 at the age of fifty-seven years, was actively interested in science and letters. He was at the time of his death president of the Imperial Academy of Sciences.

DR. JOHANNES SCHLUNCK and Dr. Erich Meyer, geologists, of the German survey, have been killed in the war.

LEAD is one of the first metals that would naturally be associated with an increased consumption in time of war, and yet the exports of lead from the United States to Europe since the war began have not increased in proportion to the increase in exports of zinc and some other metals, and the price of lead instead of being enhanced by the war actually slumped in the last fifteen years. These and other facts are graphically presented in the advance statement of the production of lead in the United States in 1914, just issued by the United States Geological Survey. The total production of refined lead from both domestic and foreign ores was 542,122 short tons, compared with 463,460 tons in 1913. The production of refined lead from domestic ores was 512,784 tons, an increase of 100,916 tons over the record figures reached in 1913. This increase was due chiefly to gains in Missouri, about 42,000 tons; in Idaho, 40,000 tons, and in Utah, 18,000 tons. The exports of lead smelted from foreign ores were 80,944 tons and from domestic lead ores 58,722 tons, a total of 89,666 tons, larger than in any other

year since 1911, when the exports of lead aggregated 113,807 tons. No domestic pig lead had ever been exported from the United States prior to 1914. Generally the price of lead in this country, owing to the tariff, exceeds the price abroad. Lead smelted in bond from foreign ores is therefore exported instead of domestic lead. Owing to the civil war in Mexico the imports of Mexican ore for the last few years have been much smaller than heretofore, and there was not enough foreign lead in the United States to supply the demand. Lead was consistently higher in London in 1914 than in New York, and this, together with the scarcity of Mexican lead, caused the large exports of domestic lead.

UNIVERSITY AND EDUCATIONAL NEWS

DR. ARTHUR A. NOYES, of the Massachusetts Institute of Technology, is to become a member of the faculty of the Throop College of Technology, Pasadena, Cal., for a portion of the coming academic year, and for one half of the time in succeeding years, beginning with 1916-17, this arrangement having been made possible by a gift of \$10,000 for the equipment of a physical chemistry laboratory, and the endowment of this laboratory in a sum yielding \$10,000 annually for its support. This laboratory is to be located in a new chemistry building, which is expected to be built during the coming academic year.

PROFESSOR ROBERT L. SACKETT, formerly of the civil engineering school of Purdue University, Lafayette, Ind., has been appointed dean of the engineering school of Pennsylvania State College. Professor Sackett succeeds Professor John Price Jackson, who is now commissioner of labor for the state of Pennsylvania.

At the laboratories of the New York Post-graduate Medical School and Hospital, Dr. Ward J. MacNeal has been appointed director to succeed Dr. Jonathan Wright, resigned. The following promotions have been made: Dr. Morris S. Fine to be adjunct professor of pathological chemistry; Dr. Richard M. Taylor to be adjunct professor of pathology;

Dr. Paul A. Schule to be lecturer in bacteriology.

Dr. FLORENCE PEEBLES, of Bryn Mawr, has been appointed professor of biology in Newcomb College, Tulane University, New Orleans.

ASSISTANT PROFESSOR HAROLD A. EVERETT, of the department of naval architecture and marine engineering of the Massachusetts Institute of Technology, has been appointed to the position of professor of marine engineering in the post-graduate department of the United States Naval Academy at Annapolis.

HENRY JOSEF QUAYLE has been promoted to a full professorship of entomology in the citrus experiment station and graduate school of tropical agriculture of the University of California.

Mr. H. SCOTT, of Trinity College, Cambridge, has been appointed curator in entomology in the university.

DISCUSSION AND CORRESPONDENCE

THE FUNDAMENTAL EQUATION OF MECHANICS AGAIN

TO THE EDITOR OF SCIENCE: I have followed with the utmost interest the correspondence in SCIENCE on the proper method of teaching the relation between force, mass and acceleration, and have heretofore refrained from adding to the discussion. I am mindful that there must be many readers of SCIENCE who have not had any advanced courses in mechanics, but who are trying to present to their students this equation, adaptable to any system of units, in a way that does not seem artificial. The difficulty of teaching this properly to students who have had little practical experience, and no occasion to do any amount of computing, and who will probably not go beyond their first course in physics, must be apparent to all. At the risk of being hissed out, I beg your leave to state a method often used, and which I have always found very successful with my classes at Wells College.

I follow a program very much like that outlined by Gordon S. Fuleher in your issue of April 30. I teach the dependence of acceleration on force, using the same mass, etc.; and set up equations in the form of proportions. The combined equation would then be

$$\frac{F}{F_0} = \frac{M}{M_0} \frac{A}{A_0}$$

Then following a method similar to that used in books on geometry in the treatment of the area of a rectangle, I say that we may take as our unit of force that force which gives to unit mass a unit acceleration. Then numerically $F=MA$; if the unit of mass be the gram, and of acceleration, the cm. per sec. per sec., then the unit of force is called the dyne. All equations in which a force is computed by multiplying a mass by its acceleration, would give the answer in dynes. But the dyne is inconveniently small. A more natural unit is the weight of a kilo. To obtain the force expressed in the larger unit, "we divide the answer expressed in the smaller units by the number of the smaller units contained in the larger unit." Then I go on to explain that this procedure of taking natural units is very common: one person is head and shoulders above another, a certain type of tree is about twice the height of a man, etc. If you multiply the number of square yards in a floor by the price (in cents) of one square yard of carpet, and you want the answer in dollars, divide by the number of cents in a dollar.

It is easy, then, to go over to the British system, in which we have but an artificial analogue of the dyne. Let us fetch that backward baby, the poundal, into the room for an inspection, at least long enough to learn that the weight of a pound is 32 poundals. Then remembering that, for instance, centripetal force, $=mv^2/r$, is in absolute units, we get that force in pounds' weight by dividing by 32.

I have little sympathy for those who "inflict" on their students such absurd ideas as that we measure sugar, stones or anything else in one kind of pounds, but use a different pound when we find the force necessary to accelerate that mass. And the idea of a gravitational is equally bizarre.

As for the metric system, I am almost discouraged at the conservatism of this progressive (!) nation. It is perfectly true that it would involve a large expense to change our manufacturing machinery to conform to the

metric standards, but this could happen slowly. Now that so much is said of scientific management, have the owners of large plants ever taken the trouble to estimate the time spent by their computers on account of our adherence to an archaic system? While abroad, I bought me a carpenter's rule in the metric system, and use this in my shop except when I have to use machinery built on the British system. I make fewer mistakes, and have far less difficulty in reading a metric rule than one graduated to sixteenths of an inch.

The metric system has the advantage in classes in physics that we can spend most of our time on physics, and comparatively little on arithmetic, and perhaps our pupils may help to demand the metric system as the universal standard.

PAUL F. GAHR

PSYLLIDÆ WINTERING ON CONIFERS ABOUT
WASHINGTON, D. C.

THE fact that certain Psyllidæ spend the winter upon conifers is well known,¹ but little has been put on record concerning this habit in the United States. In the vicinity of Washington five species of Psyllidæ abundantly winter on *Pinus virginiana*. I have more than once taken all five on the same day. On a bright day they are very active, hopping quite as vigorously as in summer. The list includes *Livia maculipennis* Fitch, *L. vernalis* Fitch, *Aphalara caltha* Linn., *Trioxa salicis* Mally, and *T. tripunctata* Fitch. The true food plant or host on which these species breed in no case is pine, the conifer being used only as an alternate food plant and winter shelter. The habit of resorting to conifers is not restricted to the cold season, however, as the records show. *Livia vernalis* has been taken on pine in June, July and September, also, *Aphalara caltha* in April, and *Trioxa tripunctata* in April, May and June.

These Psyllidæ occur on *Pinus* *tada* also, and to some extent on *Juniperus virginiana*. Another species of Psyllid—*Pachypsylla c-mamma* Riley—occurs from October to February at least upon juniper and hemlock.

Wintering specimens of two of these species

¹See especially Reuter, O. M., "Hemipteren-Fauna der Palaearktischen coniferen," 1908.

of Psyllidæ differ in appearance from the summer forms. In *Aphalara caltha* the colors are more pronounced in winter specimens, and in *Trioxa salicis* many individuals taken at this season are notably more pruinose than the summer form.

Besides psyllids, a variety of other insects resort to pines in winter. They include leaf-hoppers of the genera *Empoasca*, *Erythroneura*, *Balclutha*, and *Idiocerus*, the cercopid, *Olasptera*, and the Heteroptera, *Lygus pratensis* Linn., and *Pisema cinerea* Say. *Aradus cinnamomeus* Panz. occurs on these trees throughout the year. The assemblage of winter guests on pine includes also small sawflies, and other hymenoptera, numerous diptera, especially Chironomidae, and a few beetles and spiders. By beating conifers, scaling off bark, searching through fallen leaves, and sifting, I have made as numerous and varied a catch on many a winter's day, as I have on some days during the more favored season. I may mention that I sought in vain for Psyllidæ on pines in Maine in early March, getting only diptera and spiders.

W. L. McATEE

SCIENTIFIC BOOKS

Medicine in China. By the China Medical Commission of the Rockefeller Foundation. New York, 1914.

This volume, containing 118 pages including the appendices, is a summary of the investigations of Chinese medicine by a commission appointed by the Rockefeller Foundation early in 1914. The commission consisted of President Judson, of the University of Chicago; Roger S. Greene, consul-general of the United States at Hankow; Dr. F. W. Peabody, of the Harvard Medical School, and George Baldwin McKibbin. The purpose of the commission was to study the medical schools, hospitals and dispensaries of China with reference to the needs of the country and the desirability of aiding these institutions financially or otherwise. The commission has produced a report which is not only informing, but is full of interest and written in non-technical language.

The statement of the committee that China

probably has the largest death rate of any country in the world is probably correct. The responsibility for this lies fundamentally in the lack of knowledge of both personal and public hygiene on the part of the Chinese people, and in the lack of properly trained physicians, nurses and sanitarians to disseminate such knowledge. The tremendous mortality from which the Chinese suffer is, in the main, due to diseases of parasitic origin. Tuberculosis is widespread, and hookworm and syphilis compete with it as the important causes of death. In addition to these persistent causes, recurrent waves of epidemic disease carry death and destruction to various parts of the great Chinese Empire. Cholera, typhus fever and the plague may be mentioned in this connection. An attack of smallpox is taken for granted by the natives, just as it was in the western world before the introduction of vaccination. The report contains no information as to the prevalence of the degenerative diseases which are increasing so ominously in the United States, but it is safe to assume that they also are present and doing their share of destruction. The most hopeful feature of the health conditions in China lies in the fact that the prevalent causes of death are diseases of infectious origin, many of whose causes are already known and many of which have been almost stamped out, or at any rate considerably restricted, by modern methods of sanitation. The fact also that there are signs that the more intelligent among the Chinese themselves show evidences of an awakening interest in public health matters is of great significance.

The present condition of native Chinese medicine and surgery produces effects more serious and more widespread than the report of the commission would indicate. Doubtless this aspect of the subject has been purposely somewhat lightly touched upon; for the report, to produce its best results in China, must of necessity avoid engendering antagonism. The conditions of knowledge and practise in China to-day are not unlike those which obtained in ancient Greece and Rome. No regulation of practise, in our sense of the word, exists. Any

ignorant fakir can practise, and practise is purely empirical. The Chinese prejudices against the dissection of the human body have prevented the development of medicine upon a sound basis of anatomy and pathology, and have resulted in an ignorance concerning these subjects that would be laughable were its remote effects on the public not so terrible. It would be difficult to estimate, according to those who have lived in China, the amount of suffering which results from the lack of knowledge of the Chinese practitioner; and this is not confined to remote country districts, many large cities containing not a single medical practitioner trained in western methods. The few Chinese who have been so trained are mainly connected with the missionary hospitals and are, most of them, graduates of second-grade Japanese schools with low entrance requirements.

The medical schools of China have in the main developed in connection with the hospitals as the result of the urgent need for assistants in hospital work. In a sense, therefore, the development of the Chinese medical school has followed along the developmental lines of the British medical school, rather than the German or the American one. The schools which exist at the present time are, most of them, conducted in association with missionary hospitals and each is usually supported by the cooperation of several missionary societies. In addition to these schools, there are a few government schools, mostly under Japanese influence, and a few independent schools affiliated with American universities such as those associated with Harvard, the University of Pennsylvania and Yale. It is clear from the report of the commission that, as in this country, the medical schools have grown up haphazard at various points, doubtless as the result of very real needs, but, nevertheless, without careful study of the country as a whole in its geographical and educational relation to medical training. Practically none of the existing medical schools is adequately equipped according to western standards. Most of the schools lack the financial resources so necessary to maintain a high-grade medical school.

Practically none of them possess an adequate corps of properly trained instructors able to devote their entire time to the work. The influence of political, sectarian and in some instances personal domination, have been detrimental to the best development of some of the schools. The availability of properly qualified students has not always been considered in the development of Chinese medical schools, nor has cooperation with the Chinese themselves always been developed as it might. There are too many weak schools, and in certain places duplication of effort is to be observed.

The hospitals in China are administered for the most part by the missionary societies. There are a few Chinese Red Cross and government hospitals maintained by foreign organizations other than the religious ones. Many of the hospitals are well constructed along modern lines, but a large number are housed in remodelled dwellings which are more or less unsatisfactory for hospital purposes. The possibility of constructing satisfactory hospitals is not lacking, for building material is available and cheap almost everywhere in China, and labor is likewise cheap. From the standpoint of the construction of modern plants there are, however, some serious drawbacks which scarcely come into account with us. The lack of public sewage systems, the absence of public water supplies even in the large cities, and the lack of gas and electricity in most parts of China make difficult, but by no means impossible, satisfactory hospital conditions. The main difficulties at present have to do with the human rather than the mechanical factors. Practically no Chinese hospital in existence is sufficiently supplied with properly trained physicians. Even more important is the lack of properly trained nurses. The prejudices of the Chinese themselves interfere with smooth and satisfactory administration. The dislike of bathing (a peculiarity not confined to the Chinese), the filthy habits, the vermin-infested clothing of the patients, and the fact that in many hospitals a patient is allowed to bring members of his family permanently into the hospital with him, do not add to the ease of administration. In the dis-

pensaries too, most of which act as feeders to the hospital, the same lack of physicians and nurses is apparent. It is, I think, a fair criticism that in many instances the western physicians in charge of Chinese hospitals have deferred too much to the customs of the Chinese people under the mistaken assumption that this was necessary in order to gain their patronage. There is ample evidence in the report that the opposite point of view, namely, that admission to the hospital is a privilege which the Chinese must pay for by a compliance with the western rules of hygiene, works out well in the end. Indeed, it is obvious that the function of a hospital, not only in China, but anywhere in the world, is not only to administer to the individual patients, but also to spread through them a knowledge of the methods of personal and public hygiene. This certainly can not be done by catering to their unhygienic habits.

The cause underlying the lack of sufficient medical and nursing help in Chinese hospitals is worthy of consideration. It is, apparently, not entirely a financial question, though the salaries paid are, we think, too low. It is poor policy to pay a professional man so low a salary that he spends important energy in making both ends meet which he should be spending on his professional work. It is probable, however, that other reasons than mere salary play an important part in the difficulties attendant upon obtaining physicians and nurses for medical work in the Chinese Empire. So far as the physicians are concerned it must be pointed out that the changes in medical education of the past twenty years, with the natural growth of hospitals and public health work, have resulted in a diminution of the physicians graduating, with a great increase in the opportunities. It is likely, therefore, that the supply of missionary physicians for China will be limited to the comparatively small proportion of medical graduates whose religious fervor or adventurous spirit is appealed to by the great opportunities which undoubtedly exist in the east. The same will doubtless be true of the nursing profession.

The question of the standards of medical

education which are to be upheld in China can surely be settled if the experiences of this country are taken into account. It is clear from American experience with low-grade medical schools catering to students with inadequate preliminary training that inestimable damage may be done, both to the medical profession and to the public, by a policy which permits of such a condition, even though it is proposed with the best of motives. The only rational view, looking ahead into the future, is that those responsible for medical education in China must demand an adequate medical training based upon a sufficient preliminary education, including the fundamental sciences. There is little question that education in China is changing with great rapidity. It seems clear that the social status of the physician is growing in popular respect. It is probable that the number of well-trained young men who are anxious to study medicine is constantly on the increase. Further than this, some of the great obstacles to satisfactory education in medicine, notably the Chinese objection to dissection, are gradually being overcome, and there is evidence that the attitude of the Chinese authorities towards western medicine is rapidly becoming more and more favorable.

The question of the language to be used as a medium for the instruction of the Chinese in medicine is also a matter of dispute even among those who have spent years in China. The most potent argument in favor of a foreign language, such as English, seems to be the lack of literature in the Chinese language. The day has gone by when medicine can be studied by means of text-books alone. Further than this, the medical man must be a student all his life and a student of current literature. There are doubtless many weighty reasons against the use of the English language in Chinese medical education. Few of them, we believe, can have the importance of this one in favor of it.

The recommendations of the commission seem to be founded on a fair estimate of the needs of the situation based on an impartial review of the facts obtained. They suggest the financial support of certain medical schools

which are well situated and are capable of requiring and enforcing high standards of medical education. They provide for the establishment of model tuberculosis hospitals and aid in developing the general hospitals which serve the medical schools. They suggest the creation of scholarships for Chinese medical students and nurses, and fellowships for Chinese graduates and western medical workers in China who may wish to refresh their knowledge. They encourage the development of one or two well-equipped medical libraries and the advancement of laboratory and research work. All of the activities are to be carried on under the general supervision of a resident commissioner and an advisory committee.

It would be unfair to conclude this review without mentioning one fact that the report clearly indicates, viz., that an enormous amount of unselfish work has been performed under the most adverse and discouraging conditions by the western medical men and nurses now in the Chinese Empire. It is clear that there are practically no medical institutions in China where ideal conditions are to be met with. The lack of funds, the lack of physicians and nurses, the lack of proper buildings and equipment, the traditions of the people, all of them combine to make medical life in China anything but a bed of roses. But after all, these very deficiencies can not fail to appeal to the imagination of medical men and of nurses who are imbued with the desire for service coupled with the spirit of the pioneer. For to the pioneer, more than to all others, comes the joy of the struggle with the crude and the unfinished, and the satisfaction of leaving in its place a finished product stamped with the individuality of the worker.

GEORGE BLUMER

YALE UNIVERSITY

Die Lichtelektrizität. Von WILHELM HALLWACHS. Akademische Verlagsgesellschaft Leipzig, Germany. Mit 19 Figuren in Text. Pp. xi + 1-343.

This is, in all respects, the most compendious and complete treatise on photo-electricity which has yet appeared. Being written by one who is credited by Hertz himself with the discovery

of the real nature of the effect of ultra-violet light in facilitating discharge, and in honor of whom the phenomena of photo-electricity are not infrequently called "The Hallwachs Effect," one too whose laboratory has been perhaps the most continuous and prolific contributor to the literature on the subject, this book gains an authoritativeness which none of its predecessors can claim.

In addition, the book has been written with an admirable objectiveness and freedom from bias of either a national or personal kind. All experimental work is reported fairly and fully, and all theories are presented from the points of view of their authors. Professor Hallwachs does not hesitate to state his own convictions, but he never seeks to impose them. If only the scholars and statesmen had carried over into political affairs the method and spirit which Hallwachs here exemplifies, there would have been no great war.

Professor Hallwachs divides his historical survey of photo-electricity into two periods: the first period extends from the discovery of the photo-electric effect in 1887 to the year 1900; the second period covers the period from 1900 up to the present. This division is probably due to the fact that the interpretation of all electrical phenomena from the standpoint of the electron theory began about 1900.

The first two hundred pages constitute an exceedingly valuable digest of all the experimental work done up to August, 1913. In the 11th Chapter, too, this summary is extended so as to include all articles which appeared up to the end of the year 1913. Some of the most interesting photo-electric developments which have appeared since 1913, especially those having to do with the relations of Planck's h to the initial energy of emission and the relation of gases to photo-electric discharge, could not be included at the date at which the book went to press.

The portions of the book thus far considered make it an invaluable reference book to every student of photo-electricity. But it is in the thirty-five pages included in Chapter 9 that the greatest interest in the book will center, for it is in this chapter, which is entitled

"Ueber den lichtelektrischen Grundprozess; Versuche einer speziellen Deutung der Lichtelektrischen Vorgänge," that the author reviews and weighs all attempts which have been made thus far at an interpretation of photo-electric results. He does not commit himself to a belief in any theory thus far formulated. He gives, however, a very clear exposition of the strength and weaknesses of the theories which are at present before the scientific world.

R. A. MILLIKAN

UNIVERSITY OF CHICAGO

Sewage Purification and Disposal. By G. BERTRAM KERSHAW. London, Cambridge University Press, 1915. Pp. x+340, 56 figures.

Although books on sewage purification and disposal are becoming increasingly numerous this new work of Mr. Kershaw's is a welcome addition to the list. The author was engineer to the Royal Commission on Sewage Disposal for many years and has a well-deserved reputation not only in England, but in this country. No one has had a better opportunity than he has had to study the various methods of sewage treatment under English conditions.

The present volume is a recapitulation of some of the previous works of the author and is published as one of the Cambridge Public Health series. It deals chiefly with the methods which have shown their value by experience and does not pretend to cover some of the newer processes which are now in the experimental state. For this reason it is a more satisfactory book to place in the hands of students than are those which do not take pains to discriminate between the old and the new, the tried and the untried. Throughout the book there is frequent reference to the cost of processes. The data are valuable, but American readers must remember that the conditions in England are different from those in the United States, and in general it will be necessary to nearly double the English prices in order to make them applicable to conditions in America.

The author omits entirely the subject of disposal of sewage by dilution as that subject

is to be dealt with in a forthcoming volume in the Cambridge Public Health Series by Dr. W. E. Adeney. This also will be welcomed by American readers. Another omission is that of the process so largely and successfully used in New England, the process of intermittent sand-filtration.

The author's treatment of septic tanks and their limitations is extremely interesting. He describes not only the hydrolytic tank by Dr. Travis and the Imhoff tank, but also the Kremer and Fieldhouse tanks, which are not as well known in this country. Greater attention is given to the disposal of sludge than in many books and the subject of trade wastes and their disposal is also treated at considerable length.

G. C. WHIPPLE

HARVARD UNIVERSITY

PROCEEDINGS OF THE NATIONAL ACADEMY OF SCIENCES

(NUMBER 5)

The fifth number of volume 1 of the *Proceedings of the National Academy of Sciences* contains the following articles:

1. *Some Problems in Stellar Photometry*: JOEL STEBBINS, Astronomical Observatory, University of Illinois.

This was a part of the address of Mr. Stebbins as Draper Medallist before the Academy on April 20, 1915. It contains a number of suggestions as to probably fruitful methods and problems of stellar research with the aid of the photometer.

2. *The Composition of Brachiopod Shells*: F. W. CLARKE and W. C. WHEELER, United States Geological Survey, Washington.

The authors present an investigation to determine, more definitely than hitherto, just what substances are contributed by each group of marine invertebrates to the marine sediments, with a special reference to the formation of magnesian and phosphatic limestone.

3. *On the Occurrence of the Line 4,686A and the Related Series of Lines in the Spectra of the Planetary-Nebulae*: W. H. WRIGHT, Lick Observatory, University of California.

The line 4,686A and related series of lines as observed in the spectra of heavenly bodies, and more recently obtained from laboratory sources, have played an important rôle in some theories of the constitution of atoms; and Mr. Wright here presents a number of observations concerning the different forms in which line 4,686 occurs in nebula. In particular, he observes that it appears either as a narrow line in the nebulosity or as a broad band in the nucleus; rarely in both forms.

4. *The Nature of Nerve Conduction in Cassiopea*: A. G. MAYER, Department of Marine Biology, Carnegie Institution of Washington.

The nature of nerve conduction appears to be some chemical reaction involving the adsorbed sodium, calcium and potassium cations, and its rate is proportional to the concentration of these adsorbed ions, and is thus a surface effect. The work, therefore, supports other recent work by Tashiro and Lillie.

5. *A New Canonical Form of the Elliptic Integral*: B. I. MILLER, Department of Mathematics, Johns Hopkins University.

A new canonical form of the elliptic integral is suggested which has the advantages over the Klein-Bianchi form that it is simpler in form, unique and invariant under certain transformations.

6. *The Structure of Complex Atoms and the Changes of Mass and Weight involved in their Formation*: W. D. HARKINS and E. D. WILSON, Kent Chemical Laboratory, University of Chicago.

This is a contribution to a subject at present very widely discussed as to the nature of the atom. The authors find that it is possible to construct the various atoms of low atomic weight out of the helium and hydrogen atoms. The departure of the atomic weights from integral values on the hydrogen basis is attributed to the fact that the interference of the electric charges in the nucleus of the helium atom produces a diminution of the electromagnetic mass sufficient to lower the atomic weight; and close coincidence of the atomic weights with integral values on the oxygen basis is taken to indicate that the diminution

of mass occurs mostly in the formation of the helium atom and scarcely at all in the combination of helium and hydrogen atoms into the atoms of higher atomic weight.

7. *Huntington's Chorea in Relation to Heredity and Eugenics*: C. B. DAVENPORT, Station for Experimental Evolution, Carnegie Institution of Washington.

Nearly 1,000 cases of Huntington's chorea are traced back to some half dozen individuals. The choreic movements never skip a generation and in other respects show themselves clearly to be a dominant trait; nevertheless, there is no clear evidence that persons belonging to the choreic lines voluntarily abstain from marriage, or are selected against in marriage.

8. *The Alcyonaria as a Factor in Reef Limestone Formation*: L. R. CARY, Department of Biology, Princeton University.

To determine the amount of material contributed to reef formation by the gorgonians three factors are taken into consideration: first, the amount of lime held as spicules in the tissues of these colonies; second, the bulk of the gorgonians present on any reef area; and third, the number of colonies which will set free their spicules through the death and subsequent disintegration of their coenenchyma.

9. *Transformations of Conjugate Systems with Equal Invariants*: L. P. EISENHART, Department of Mathematics, Princeton University.

The author has previously described what he has called "transformation K " and "transformations Ω "; and in this note he shows that there is a fundamental relation connecting those transformations.

10. *On the Pole Effect in the Iron Arc*: O. E. ST. JOHN and H. D. BABCOCK, Mount Wilson Solar Observatory, Carnegie Institution of Washington.

In a continuation of their communication in the March number of the *Proceedings*, the authors find that it is necessary to consider the pole effect in the determination of wavelengths in international units. The wavelengths are not affected by wide variations of

density of the radiating vapor and appear to be independent of changes in temperature. The pole effect does not occur in vacuo and appears independent of electrical conditions.

11. *Inheritance in the Asexual Reproduction of Hydra Viridis*: K. S. LASHLEY, Zoological Laboratory, Johns Hopkins University.

This investigation aims to contribute to the answer of the questions: Do heritable variations commonly occur among the offspring of a single individual multiplying asexually? and may selection among such offspring produce strains differing in hereditary characters? He finds that the only effect of selection is a temporary change in the vigor of the selected polyps and that there is no cumulative inheritance of variations in the number of tentacles within the clone. There is some evidence that the same conclusions apply to the inheritance of size.

12. *On the Monticellite-like Mineral in Meteorites and on Oldhamite as a Meteoric Constituent*: G. P. MERRILL, Department of Geology, United States National Museum, Washington.

The author has subjected to microchemical analysis and to optical study the colorless mineral whose presence in chondritic meteorites has been observed by several previous investigators. He presents sectional drawings showing the appearance and optical properties of the mineral, which appears to be a form of calcium phosphate. He also calls attention to the presence of oldhamite (calcium sulphide) in meteorites from various sources.

13. *Absolute Scales of Photographic and Photovisual Magnitude*: F. H. SEARES, Mount Wilson Solar Observatory, Carnegie Institution of Washington.

Mr. Seares describes the arrangement at the Mount Wilson Observatory for determining absolute scales of photographic and photovisual magnitudes extending over about 17½ magnitudes for the photographic scale and about 15½ for the photovisual scale. The various difficulties which are met in comparing stars so different in brightness as is implied in these ranges of magnitudes are discussed,

and the details of the method employed are indicated.

14 Mitosis in *Trichomonas*: O. A. KOROM and O. SWERZ, Zoological Laboratory, University of California.

The authors conclude that cell-division in trichomonad flagellates is a true mitosis with differentiated chromosomes, which split longitudinally prior to their location in the equatorial plate; that the nuclear membrane persists throughout mitosis; that the paradesmose between the migrating blepharoplasts is extranuclear at all times, disappears after nuclear division, and does not give rise to the axostyle; and that the axostyle splits longitudinally and thus forms two daughter axostyles.

The number concludes with the report of the annual meeting (which has already appeared in *SCIENCE*) by the home secretary, and with announcements of the research grants made from the trust funds of the academy during the preceding year.

SPECIAL ARTICLES

THE CONTINUOUS SPECTRA OF GASES

In spectroscopic literature there are many casual references to a continuous background in the vacuum-tube spectra of various gases, such as oxygen, chlorine, etc. Usually these observations appear to have been confined to the visible region, and I can recall no comments on continuous spectra in the ultra-violet except in the case of hydrogen. Schneiderjost¹ and Friederichs² observed such a spectrum at low pressures, which extended to a wave-length of about 2,100. The latter attempted to use the uncondensed discharge through a small capillary tube at about 2 mm. pressure as a source for the photography of absorption spectra, but found that the results were unsatisfactory, even with exposures varying from twelve to twenty-four hours.

In photographs of the hydrogen spectrum obtained with a large two-prism quartz spectrograph I have frequently observed this continuous spectrum. Although the resolving power of this spectrograph in the extreme ultra-

¹ Schneiderjost, *Zt. f. Wiss. Phot.*, p. 265, 1904.

² Friederichs, *Bonn Diss.*, 1906.

violet is greater than that of a five-inch grating in the first order, there is no evidence of resolution into lines or bands. The spectrum appears to be uniformly continuous, and it seems likely that its gradual fading out in approaching the wave-length 2,100 is due rather to the absorption of the thick quartz system than to the lack of these wave-lengths in the emitted light. It appears to be due to pure hydrogen, for successive improvements in purity due to the removal of oxygen, water vapor, and nitrogen cause no noticeable change; nor does the addition of a trace of oxygen to hydrogen previously freed from that gas as far as possible cause any appreciable difference.

It seems very unlikely that a continuous spectrum can arise from free vibrations within the atom or molecule, hence it has been usually ascribed to molecular collisions. In comparing different gases at the same pressure, the number of collisions would depend mostly on the mean velocity of the molecules, so that the number of collisions would rapidly diminish as the molecular weight increases; hence we might expect that the continuous spectrum of a light gas would be stronger than that of a heavier gas. This was found to hold good for hydrogen, helium and neon. Photographs were obtained of the spectra of these three gases in vacuum tubes prepared by Hilger. The pressure was about the same in all. With a two-minute exposure, the continuous spectrum of hydrogen was very intense; that of helium about half as strong, and that of neon about one third as strong. They all extended to about the same limit—that set by the transparency of the quartz. In all these cases the uncondensed discharge of a medium-sized induction coil was used. The introduction of a condenser almost completely obliterated the continuous spectrum. When a condenser is used the radiation probably comes from dissociated ions, with free periods little disturbed by molecular collisions.

Nitrogen, krypton and xenon did not show any continuous spectrum.

Some tests showed that hydrogen tubes may render excellent service as sources for the

study of absorption spectra in the ultra-violet. It was not found advisable to use capillary tubes, nor to work at such low pressures as Friederichs did. The best results were obtained with end-on tubes, from 5 to 10 mm. in diameter and about 80 cm. long, with quartz windows, and at pressures in the neighborhood of 5 mm. The necessary exposure varies from 5 minutes to an hour, according to the width of the slit, the absorptive power of the medium, etc. I have obtained a beautiful photograph of the absorption spectrum of benzol vapor with fifteen minutes' exposure.

E. P. LEWIS

UNIVERSITY OF CALIFORNIA,
May 18, 1915

THE IOWA ACADEMY OF SCIENCE

THE twenty-ninth annual session of the Iowa Academy of Science was held in the Hall of Physics, State University of Iowa, Iowa City, on April 30 and May 1, 1915. Over one hundred members were registered. At the opening session on Friday afternoon, after the transaction of preliminary business, the president, Professor H. S. Conard, called for the presentation of papers of general interest. At 4 p.m. the academy separated into sections for the further reading of papers as follows: section one, botany; section two, physics, chemistry and mathematics; section three, zoology, geology, psychology, medicine.

Professor Ellery W. Davis, of the department of mathematics in the University of Nebraska, gave the annual address on the subject "Uncertainties," a discussion of the foundations of exact knowledge.

On Saturday morning the sections resumed their meetings, except that the Iowa section of the American Chemical Society met independently. At the business meeting the following officers were elected for the coming year.

President: Harry M. Kelly, Mount Vernon.

First Vice-president: G. W. Stewart, Iowa City.

Second Vice-president: Charles R. Keyes, Des Moines.

Secretary: James H. Lees, Des Moines.

Treasurer: A. O. Thomas, Iowa City.

The sectional meetings were so successful that a continuation of the plan was decided upon for the next annual meeting.

Luncheons were enjoyed on Friday evening by the geologists and geographers as guests of Dr.

and Mrs. Kay, by the mathematicians and by the physicists. A general luncheon was participated in by the members of the academy on Saturday noon, following the business session.

Program

(Abstracts are by the authors.)

Preliminary Notes on Nectar Production: L. A. KENYER.

An Anomalous Hickory-nut; An *Exobasidium* on *Armillaria*; The Role of Soil Fungi: GUY WEST WILSON.

The Forest and Shrub Flora of Western Iowa: L. H. PAMMEL, G. B. MACDONALD AND H. B. CLARK.

This paper discussed the distribution of trees and shrubs of the drainage basin of the Missouri River and some of its tributaries. A number of southern species like *Cercia canadensis* and *Asimina triloba*, *Quercus acuminata* and *Vitis cinerea* reach their northern distribution in Fremont County.

The Weed Flora of the Lake Superior Region Compared with the Weed Flora of Iowa: L. H. PAMMEL.

A brief comparative study of the distribution of weeds of the northern lake region and the prairie region of Iowa.

Some Comparative Germination Tests of Sweet Clover: H. S. DOTT.

A test of the germination of sweet clover treated with sulphuric acid, scratching, freezing and the Hughes method. It was found that scarification, freezing and the acid hastened the germination of seeds.

The Flora of the Ledges, Boone County, Iowa: WM. DIEHL, presented by L. H. PAMMEL.

A systematic catalogue of the spermatophytes and ferns of the ledges comprising a small area of Carboniferous sandstone along Pease Creek, a small stream which empties into the Des Moines. In this region occur a number of species of local range like *Quercus acuminata*, *Dirca palustris*, *Juniperus virginiana*, *Physocarpus opulifolius*, *Lathyrus ochroleucus*, *Trillium nivale*, etc.

Flora of the East Slope of the Cascade Mountains in Crook County, Oregon: MERRON E. PRICE.

The paper discusses briefly the general distribution of the flora on a line drawn across the Cascade Mountains in central Oregon, then takes up more in detail the plants occurring on the lower portion of the eastern slope, namely, at the town of Sisters. A study of these indicates that the locality is

typically arid transition. There follows an annotated list of plants recorded by the writer on a trip across the arid transition in this section of the state in July, 1914.

Flora of the Rainy River Region: HARRIETTE S. KIMMEL.

In August, 1914, the writer collected plants along the south bank of the Rainy River near the "Old Dock" in the city of International Falls, Minnesota.

The territory explored consisted of a timber belt lying back from the river and cleared ground still back of this.

The timbered belt consisted largely of birches, poplars, maples and other deciduous trees interspersed with cedars and spruces and species of an arborescent nature. Underneath was the characteristic forest herb flora; the cleared ground was covered with introduced plants of a weedy character; there was an almost entire absence of strand flora. East of the dock was a luxuriant growth of tame grasses and clovers, the seed of which had been scattered when grain was carried to the dock for transportation by boat.

A few species are listed that were collected from the Canadian bank of the river, several from the Rainy Lake region and a few from the west bank of the Winnipeg River.

Economic Seaweeds of Alaska (illustrated): ROBERT B. WYLLIE.

A brief statement of the findings of the U. S. Kelp Expedition which made a survey of the potash-yielding seaweeds of southeastern Alaska during the summer of 1913.

A Hybrid Ragweed (illustrated): ROBERT B. WYLLIE.

The description of a hybrid, probably a cross between *Ambrosia artemisiifolia* and *A. trifida*, found near Iowa City during the summer of 1914.

The Distribution of Forest and Prairie in the Lake Region of Iowa (with lantern slides): B. SHIMEK.

The Okoboji region is discussed. The groves appear uniformly on, or in the shelter of abrupt slopes or in rough areas consisting of a group of ridges or knobs. They are found on the leeward side of abrupt slopes anywhere about the lakes; but they occur on the windward side only on the east and north sides of the larger lakes. In the latter case the establishment of a forest seems to be made possible by the piling up of vapors under the banks on the windward side.

The Lichen Flora of the Prairies of Northwestern Iowa: B. SHIMEK.

This consists largely of xerophytic species attached to boulders. Few earth forms occur. The rock forms are most abundant on dry knolls and in exposed places. A comparison of this flora is made with that of the xerophytic borders of prairie burr oak groves. An annotated list of the species is included.

The Ecological Histology of Certain Prairie Plants: ELLA SHIMEK.

The paper discusses the xerophytic adaptation of certain species of prairie plants in detail.

Pioneer Plants on a New Levee: FRANK E. A. THONE.

A description of the plants appearing on a newly exposed surface in Des Moines, Iowa, during the first season after exposure, with remarks concerning their possible origin.

The Index of Foliar Transpiring Power as an Indicator of Permanent Wiltting of Plants: ARTHUR BAKER.

Some Well-known Building Stones: NICHOLAS KNIGHT.

An analysis was made of the Anston Stone, from Kiveton Park, England, the material of which the Houses of Parliament are built, to learn, if possible, the cause of the crumbling of the rock. It proved to be a dolomite, of a light buff color, with a specific gravity of 2.6.

The red sandstone from the Vosges Mountains, of which many public and private buildings in Alsace-Lorraine, including the Strasbourg Cathedral, are constructed, was studied. The rock is a hard, durable building material and lends itself to delicate carvings, as shown by the fine Gothic of the tower and facade of the cathedral.

The "Hard Jewish," a compact rock from Solomon's quarries, Jerusalem, with a specific gravity of 2.7, also was analyzed.

A New Apparatus for Regulating Temperatures for Work in Polarimetry and Refractivity; Electrical Conductivity of Solutions of Silver Nitrate in Water and Pyridine and in their Binary Mixtures (preliminary paper): J. N. PEARCE.

A Convenient Standard Cell—(Cu—Hg)—CuSO₄—Hg₂SO₄—Hg: DIEU UNG HUONG AND J. N. PEARCE.

Some Derivatives of 4-nitro-5-methyl-2-sulphobenzoic Acid: WM. J. KARSLAKE AND P. A. BOND.
Comparison of Some Standards in Acidimetry and Alkalimetry: W. S. HENDRICKSON.

Studies on Barium Sulfate: P. L. BLUMENTHAL AND S. C. GUERNERY.

Comparison of Some Kjeldahl Methods for Nitrogen Determination: P. L. BLUMENTHAL AND G. P. PLAISANCE.

The Ste. Genevieve Formation and Its Stratigraphic Relations in Southeastern Iowa: STUART WELLER AND FRANCIS M. VAN TUYL.

Recent field studies have shown that the Pella limestone, which was formerly regarded as the uppermost subdivision of the St. Louis, is formationally distinct, being separated from the true St. Louis beneath by an unconformity and a remarkable basal sandstone. The previous reference of this member to the Ste. Genevieve upon the basis of its fauna is, therefore, borne out by the field evidence.

The Occurrence and Origin of the Iron Ores of Iron Hill, Near Waukon, Iowa: JESSE V. HOWELL. Introduced by G. F. KAY.

The Extension of the Wisconsin Drift Southwest from Des Moines: JOHN L. TILTON.

This newly recognized area of Wisconsin drift extends from Valley Junction just west of Des Moines for five miles to the south. In all directions, east, south and west, from this strip, now only about a mile wide, the topography is that of a typical area of Kansan drift.

The Age of the Terrace South of Des Moines, Iowa: JOHN L. TILTON.

A low terrace is very noticeable near Des Moines and along streams flowing into the Des Moines from Warren County. The topographic maps give evidence of a similarly related terrace further southeast and then north along the Mississippi River to within the area of Wisconsin drift in that part of the state. The terrace is composed of sand and gravel forming a continuous deposit to a depth of thirty feet, post-Wisconsin in relation, and with Wisconsin or post-Wisconsin fossils: Bison, Rangifer, Symphos.

The First Coal-washing Plant in Iowa; The Mineral Industry in Iowa During the Past Decade: GEORGE F. KAY.

The Occurrence of Barite in the Lead and Zinc Districts of Iowa, Illinois and Wisconsin: W. D. SHIPTON.

Precise Criteria of Terrane Correlation: CHARLES KEYES.

The signal failure of our state and federal geological surveys to give us working classifications of local geologic formations that are readily ad-

justable to the general continental scheme has recently led to the adoption by the various bureaus of somewhat arbitrary methods in order to make published records immediately available. In wasting about for a suitable area for which to construct a generalized section of local rocks the quadrangle, as ordinarily selected, appears to be much too small to be of any real service. The country is likewise too limited in extent. In size the state seems to be most satisfactory for trial tests in continental problems of exact correlation. A number of these generalized state sections reduced to identical taxonomic schemes are compared.

Mountain Structures in Plains: CHARLES KEYES.

The larger tectonic features of the substructure of the prairie region of the continental interior are of unusual interest because of the fact that well-defined mountain structures are now discovered here for the first time. A carefully constructed geologic cross-section extending from the northwest corner of Iowa to the southeast corner of Missouri presents one of the most perfect synclinoria known. Within this remarkable hinge are preserved our great coal deposits.

At the north end of this synclinorium is the structural remnant of old Triassic mountains, a range which in its prime was comparable to the Appalachians of to-day. At the south end is the Ozark dome of Tertiary date. Associated with the great trough is a noteworthy system of profound dislocations.

Exhumed Sea-coasts: CHARLES KEYES.

A curious geologic coincidence occurs on the shores of Puget Sound. There has been in this region during late geological times more or less oscillation of the land. In a previous cycle the hard igneous rocks were carved out by the waves into low, irregular sea-cliffs. On the sinking of the islands sands and gravels covered the belt to considerable depths. To-day, with a marked up-rising, the new shore-line is contraposed on the ancient one. In a quite remarkable way the latter is being now exhumed by the action of the waves.

Progress Report of Physiographic Work in the Driftless Area: A. C. TROWBRIDGE.

The Paleontology and Stratigraphy of the Upper Carboniferous of Iowa: GEORGE L. SMITH.

The Loss of Pease, Hungary (with lantern slides): B. SHIMKE.

A discussion of true loess and an underlying water deposit which has been classed as loess. The true loess contains a strictly terrestrial molluscan

fauna, and in some places is divisible into a lower gray, and an upper yellow division, not unlike those which are common in this country.

The fauna of the lower, horizontally stratified deposit is mixed, consisting of both land and fresh water mollusks. This part is not loess, and is clearly aqueous.

Leaching of the Pleistocene Drifts of Eastern Iowa: MORRIS M. LEIGHTON.

This paper is a discussion of the process of leaching of the calcareous constituents of the drift in the area above stated. Attention is called to the fact of a narrow transition from the leached zone into the calcareous where limestone pebbles reach their normal abundance, and the contention is set forth that this may be a factor of slow percolation and rapid saturation. The contention is also set forth that the bottom of the zone of leaching in the young drifts may not mark the so-called permanent ground-water surface, as is commonly assumed, but that it may well be above the latter.

Some Unique Niagaran Cephalopoda; A New Crinoid Fauna from Monticello, Iowa; High Level Gravels in Floyd County, Iowa: A. O. THOMAS.

The Inheritance of Syndactylism: HENRY ALBERT.

An instance of thirteen cases of syndactylism (or fused or webbed fingers or toes), traced through four generations was reported. The element of heredity is obviously apparent. In view of the recent report of a family with cases of syndactylism in which the inheritance of the abnormal union of the digits apparently conformed to Mendel's law, as a dominant character, an effort was made to determine if the Mendelian law also applied to the cases in question. It was determined that although the disease was due to a factor which was apparently dominant rather than recessive, it did not conform entirely to Mendel's law. That it is not due to a Mendelian recessive character is shown by the fact that in three instances the disease appeared in children, neither of whose parents were affected by it, and in each instance the family history of at least one of the parents was negative for the disease in question. To have a disease due to a recessive character appear in an individual, neither of whose parents are affected by it, we must assume that both parents are hybrids as regards the condition in question.

Nor does it entirely conform to a Mendelian dominant character, since if it did we would expect that if the disease appeared in the offspring it should be present in at least one of the parents.

It is probable that the explanation for the lack of conformity of our cases to Mendel's law is due to an inhibition of the activity of the determiner for the disease in question by some other factor, causing the disease in such cases to be latent. The absence or non-operation of such inhibiting factor may again cause the disease to appear.

The Effect of Alcohol on the Liver as Shown Experimentally: A. L. GROVER. Introduced by HENRY ALBERT.

The Effect of Change of Lamp Voltage on Vision: WM. KUNERTH.

This paper is an experimental determination of the change of lamp voltage permissible before it is noticed, as also of the change permissible before it really becomes objectionable to the patron. The permissible change of voltage for the different sizes of carbon lamps is determined, as also the permissible change for vacuum tungstens and nitrogen-filled tungstens.

A Simple Device for Determining the Tempered Scale: L. B. SPINNEY.

An Attempt to Detect a Change in the Heat Conductivity of Selenium Crystals Under the Influence of Light: L. P. SIEG.

Notes on Certain Elastic Peculiarities of Phosphor Bronze Wires: L. P. SIEG AND A. J. OEHLER.

On the Wave-length Sensitivity Curves of Isolated Crystals of Selenium Between Wave Lengths 2000 Å. U. and 4500 Å. U.: F. C. BROWN AND L. P. SIEG.

A Design for Electrical Regulation of High Temperature Ovens; Notes on Production, and Some Electrical Properties of Tellurium Crystals: W. E. TISDALE.

A Resonance Method for Measuring the Phase Difference of Condensers: H. L. DODGE.

The Theory of Binaural Beats.—An Experimental Contribution: G. W. STEWART AND HAROLD STILES.

The experiments here reported were performed in order to secure evidence concerning the cause of the additional maxima which occur in binaural beats.¹ These additional maxima occur at certain phase differences, and the change in these phase differences should depend upon the frequency of the tones, but not upon the frequency of the beats. If the additional maxima are caused by interaural conduction then, as it can be shown, the phase differences should vary as the frequencies. If the data are plotted, instead of the straight line which

¹ See G. W. Stewart, *Physical Review*, Series 2, 3, p. 146, 1914, for a description of the phenomena.

should obtain in the case of interaural conduction, we have a curve which is far from a straight line.

After much consideration of theories involving interaural conduction, none seems to be in agreement with the evidence here shown.

The Absence of Liberation or Absorption of Electrons During a Change from the Conducting to the Non-conducting State: L. E. DODD.

Crystals of metallic selenium were melted in a metallic cup attached to a sensitive electroscop. The heating agent was a focus of sun's rays supplied by a convex lens; this method of applying heat was used in preference to flames, which possess high ionizing powers. Previous to the change of state of the selenium the electroscop was given a negative charge. During the time required for the change of state a certain deflection of the electroscop leaf was observed. With the crystals removed from the cup, and the sun's rays focused at the same point as before, two comparison readings were made over time intervals equal to that required for the change of state. Changes of deflection resulted of similar magnitude to that first observed.

The experimental conclusion is that in metallic selenium, when it changes by melting from the crystalline and conducting form to the amorphous and insulating form, electrons are neither absorbed from, nor liberated to, the surrounding medium, in any very appreciable amount.

The Crystal Optiphone in its Adaptation to Enable the Blind to Read the Printed Page through Ear Impressions: F. C. BROWN.

The Variation, with Temperature, of the Light-sensitiveness of Selenium Crystals: KATHRYN J. DITTRICH.

The Wave-length Sensibility Curves of Selenium Blocks: E. O. DIETRICH.

Psychology Applied to the Improvement of Control of the Pitch of the Voice in Singing: CARL J. KNOCK. Introduced by C. E. SEASHORE.

Psychology Applied to Measurement of Merit in Advertisements: HARRY H. GOULD. Introduced by C. E. SEASHORE.

The Psychogram in Vocational Guidance: C. E. SEASHORE.

A Bacteriological Study of the Wells of Toledo, Iowa: W. L. LAUNDERDALE AND L. A. KENoyer.

Primary Succession, the Animal Ecology of Johnson: M. BRUMF. Introduced by GILBERT L. HOOVER.

This paper is based on an early spring survey

of the forms of animal life found in a small stream. The rapids and pools are discussed with a division of the species into particular animal associations. The species have been catalogued with brief notes as to habits and a table has been prepared giving in concrete form the distribution, food habits and relative abundance of each species.

On the Lymphatic System of the Common Rat (*Epimys norvegicus*): TARELA T. JOE.

From fifty injected specimens, the gross anatomy of the common rat has been studied and outlined. The results of the work have further proven the studies of McClure and Silvester on the lymphatic-venous communications in the jugulo-subclavian district, and of Silvester on the renal vein communications, and have established two additional communications, the portal vein connection and the ilio-lumbar vein connection. The main circulation and disposition of the lymphatic system has been determined and the need of further knowledge concerning the histology of the lymph nodes, of which there appear to be two types, is pointed out.

Notes on the Development of the Lymphatic System of Turtles: FRANK A. STROMSTEN.

The Present Status of the Hessian Fly in Iowa: R. L. WEBSTER.

Tracheal Capillaries of the Grasshopper: L. B. ROSS.

The Inheritance of Fertility in Swine: EDWARD N. WENTWORTH.

Is the Appetite of Swine a Reliable Indication of Physiological Needs? JOHN M. HYVARD.

Notes on Iowa Pentatomicea: DAYTON STOKER.

The Cow: FRED BERNINGHAUSEN.

On Snakes "Swallowing" Their Young: E. D. BALL.

A common garter snake was frequently seen to "swallow" her young. The little snakes would often push their heads out of the mother's mouth and thrust out their little tongues.

The Building and Function of the College Museum: B. H. BAILEY.

Notes on the Distribution of the Prairie Spotted Skunk in Iowa: B. H. BAILEY.

Ictinia Mississippiensis in Nebraska: B. H. BAILEY.

Published in full in the *Wilson Bulletin* of Oberlin College.
